The Congress Street plant, the newest of the four, is designed to eventually contain four 1300-hp. boilers and two 2600-hp. boilers of the "W" type. In the effort to reduce the amount of attendance labor at this plant the auxiliaries are located, for the most part, on the boiler-room floor so as to be within convenient reach of the few men constituting the operating crew. Coal is hauled from bunkers at the railroad sidings to the plant in drop-bottom buckets of 5 tons capacity, which are lifted by a crane and emptied into overhead hoppers from which the coal is distributed by belt conveyors to the boiler bunkers. Ash-handling equipment is practically nil, the boilers being set at sufficient elevation to allow wagons to be driven beneath the hoppers.

Because of the fact that only a relatively small amount of condensation is returned to the plants, careful treatment of the raw water is necessary. The feedwater flows through live-steam purifiers, operating at boiler pressure, in which the scale-forming materials are precipitated. In addition, sodium carbonate is fed in automatically graduated amounts to reduce the slight amount of hard scale-forming material which finds its way into the boiler. Although Detroit water is not a bad boiler water, these precautions are necessary because of the large percentage of make-up water and the rather high rates of steaming at which the boilers are sometimes driven.

The auxiliaries are almost entirely motor-driven. The current is supplied by a 750-kw. turbo-generator unit exhausting into an open feedwater heater. The load carried on this generator is adjusted according to the requirements for exhaust steam for heating the feedwater and any excess current generated is delivered to the outside electric-distribution system. Conversely, if the electricity requirements of the plant exceed the output of the generator, current is drawn from the outside supply. Exhaust steam is thus made available for heating the feedwater and the advantages of motor-driven auxiliaries are also secured. Moreover the turbo-generator constitutes a source of electricity supply for the plant in case of local interruption of the outside service.

Steam is generated at a pressure of 130 lb. gage. This pressure is chosen in order to provide for considerable pressure drops in the outgoing feeders as calculated for present conditions. It may be raised to 160 lb. at some future date. The outgoing steam lines leave the plant through a tunnel shaft.

Distribution System

The popularity of the heating service in Detroit has led to its development on an extensive scale. The present distribution system covers an area of about 2 miles long and half a mile wide which includes the entire central shopping, business, and financial districts and a small portion of the residence district. About 2,700,000 sq. ft. of radiation, besides numerous water heaters and cooking fixtures, are served. The distribution system contains about 20 miles of underground mains and 2 miles of tunnels. The four boiler plants which supply steam to the system contain 17,470 rated boiler hp., and they delivered in 1918 nearly two million pounds of steam to the system. Over 1700 consumers are served.

The distribution mains, though originally built in three distinct sections, are now a practically continuous network and the plants are so much interconnected that the load can readily be shifted from one to another. In spring and early autumn two of the four plants serve the entire area.

Because of the great increase in connected load the transmission capacity of the distribution network, most of which was installed several years ago, is now quite inadequate. To have raised the pressure throughout the system would have increased its capacity; but the system pressure was permanently limited

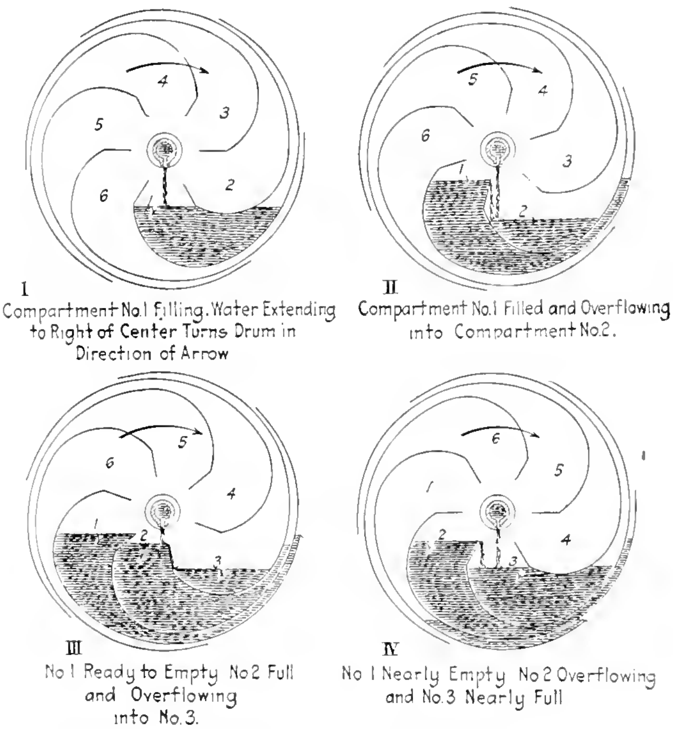

FIG. 6 CONDENSATION METER AND ITS PRINCIPLE OF OPERATION

by the fact that most of the underground fittings are of a low-pressure pattern, and temporarily by the fact that in those sections of the system formerly supplied with exhaust steam the customers' installations are not provided with reducing valves. Instead of attempting to change these conditions, which would have involved the reconstruction of much of the distribution network, the less expensive plan was adopted of running feeders from the plants to various centers of distribution. In selecting the pipe sizes for feeders, advantage is taken of the difference between boiler pressure and distribution pressure, and the size of the pipe is so chosen that at times of maximum load much or even all of this pressure drop will take place in the pipe itself. The diameter and the cost of the pipe line are thus materially reduced. In operation, the pressure of the steam delivered to the feeder is raised or lowered as required by the adjustment of a reducing valve at the plant, in order to maintain a constant pressure at the center of distribution which the feeder supplied. The pressure existing at this center of distribution is recorded at the plant by a long-distance gage, electrically operated.

The velocity of the steam flow in feeders at times of heavy load is very high. Velocities as great at 75,000 ft. per min. have

been measured. This high velocity does not appear to be at all objectionable, however, there being no apparent erosion of the pipe and no hammer, or objectionable vibration. The fact that the steam is in a superheated state because of the pressure drop is an advantage in these respects. Feeders are constructed with long radius bends and where the connection is made to the distribution mains the diameter of the pipe is gradually increased by special taper fittings so as to reconvert a portion of the velocity head to static pressure.

A considerable pressure gradient is also allowed to take place in the distribution mains as well as in the feeders; but this is relatively small, since the upper limit is fixed by the allowable working pressure of the older mains. The more recently laid mains are capable of withstanding a working pressure of 125 lb.

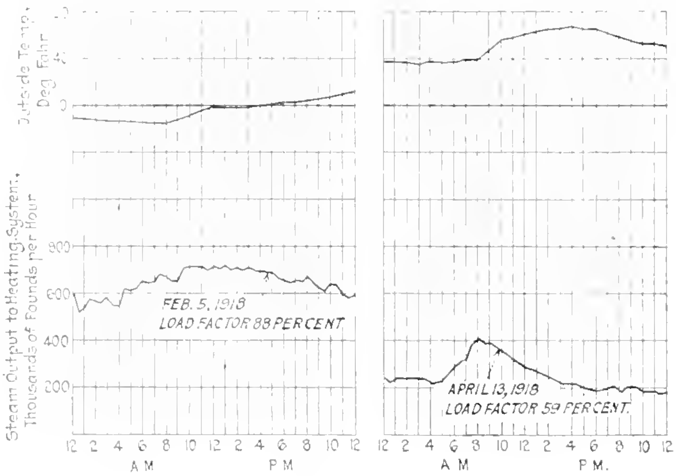

Fig. 7 Typical Load Curves of Heating System

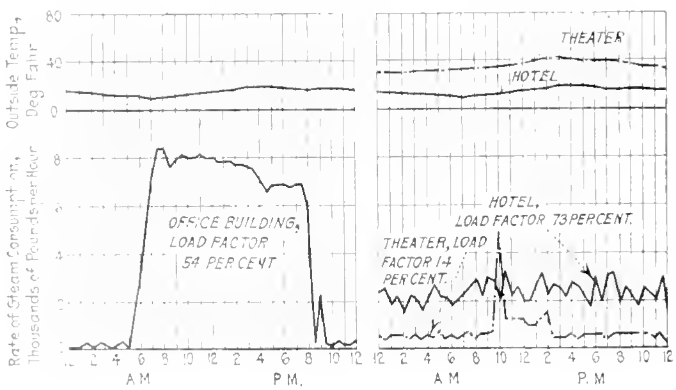

Fig. 8 Typical Load Curves of Individual Consumers

and the gradient in the mains can therefore be increased at some future date. From a standpoint of safety, however, the desirability of carrying pressures in excess of about 50 lb. on the service connections to buildings is questionable until further development in pressure-reducing apparatus is made.

This method of steam distribution is obviously an adaptation to previously existing conditions and would doubtless be modified if an entirely new system were being laid out.

Underground Construction

The distribution mains range in size from 20 in. near the stations to 4 in. at the outskirts of the system. The original underground pipes were laid in a segmental wood casing bound with wire. This construction has been fairly successful under favorable soil conditions, but the concrete conduit shown in Fig. 4 has been found to be superior in many respects and has been used exclusively for several years in all new construction. In this construction the pipe is insulated with a standard thickness of pipe covering and surrounded with an envelope of concrete poured over a wooden form, leaving an air space around the pipe. Proper underdrainage is of course essential.

The longitudinal expansion and contraction of the pipe, due to changes in its temperature, are absorbed, in the earlier construction, by means of expansion fittings of the copper-diaphragm type. In recent construction a slip joint, consisting of a brass sleeve, sliding in a packed gland, has been used. The use of slip joints decreases somewhat the cost of the pipe line as they will absorb more travel and can be placed at wider intervals than the diaphragm fitting.

The underground mains have not been laid sufficiently long to permit of an accurate estimate of their life. The oldest lines laid in wood casing have now been in service 15 years and, while the casing in many places has deteriorated considerably, in other places it is in fairly good condition. The concrete construction, dating back 10 years, seems to have deteriorated very little. The only repairs or replacements which have been made to date have been made necessary by external corrosion or pipe arising from some outside and local cause such as a water-pipe leak. An average life of 20 years for the wood-log construction and 30 years for the concrete construction would seem to be a very conservative estimate. Soil conditions in that part of the city where the heating mains are laid are particularly favorable, the soil being very well drained.

Manholes are located at intervals of about one city block (300 to 400 ft.), to house the slip joints, valves, and bleeder traps.

In the heart of the business district the pipes are in tunnels, of which there are about 2 miles, lying from 25 to 40 ft. below the street level. In cross-section they are similar to a horseshoe and are built of brick, with concrete floors. (Fig. 5.) For the most part they are about 6 ft. in height and 6 ft. wide. The tunnels are ventilated by suction fans which draw a small amount of air through them continuously and much larger amount when it becomes necessary for men to work in the tunnels. Their temperature ranges between 90 and 130 deg. fahr. When two of more pipes are to be laid under a street in a congested district it has proved desirable to build a tunnel to avoid the inconvenience to the public attendant upon tearing up the street, either for the original construction work or for subsequent changes. The tunnel permits of ready access to the pipes at any time, and since it is far below any other structures, no obstructions are met with. Tunnel construction is exceptionally simple in Detroit where the subsoil is a blue clay nearly impervious to water and well adapted to tunneling operations. The cost of tunnel construction is high but the advantages gained are compensatory.

Consumers' Installations

The consumer's equipment includes, besides the usual radiators and piping, a pressure-reducing valve, which reduces the service pressure to the lower pressure required for heating, and a trap whose function is to discharge the water of condensation from the system.

Any existing steam-heating system can be adapted for service by making a few minor changes. A hot-water system can be served with steam by substituting for the fuel-burning water heater a surface heater in which the water in the system is heated by the steam. A hot-air system can be adapted to the use of steam by substituting steam coils for the furnace and using the same duct system, though this is rarely done.

Economizer coils, utilizing the heat in the condensation, are recommended by the Company but not required. They are seldom installed in any but the largest buildings as few consumers see fit to make the necessary investment even though a demonstrated saving can be made. In some buildings the condensation is passed through a surface heater which preheats the water used for lavatory purposes, and this seems to be the most satisfactory form of economizer for large buildings.

The consumer's installation is the least reliable factor in the maintenance of uninterrupted and satisfactory service. Boiler plants can be and are designed and operated so as to be extremely

reliable. A distribution system, if properly laid out, with ample capacity and duplicate feeding routes, can be operated so that the steam supply to a building is practically never interrupted. But the consumer's piping system and the special appliances attached to it, operated by persons unfamiliar with mechanical apparatus, are a frequent source of trouble. Tagging of the valves to indicate their proper operation, distribution of printed instructions and other educational measures are employed with varying success, and the service is on the whole much more reliable than that obtained from the ordinary individual plant. A "trouble service" is maintained day and night to insure immediate attention to minor repairs and adjustments of consumers' equipment.

The regular heating season covers 8 months of the year, though summer service for cooking and water heating is supplied to a few consumers conveniently located. Cool weather in September usually makes necessary the commencement of service before the contract date of October 1. It has, in fact, been started in August. Steam was originally sold to some extent for power purposes but this service is now practically discontinued.

Meters

With the exception of a number of calibrated steam jets used in cooking fixtures, the steam is sold entirely on a condensation basis, the condensation flowing from the system through a meter and thence to the Company's return line or to the sewer.

The art of metering condensation was comparatively new when the Company commenced operations and although many advances have been made, it has not yet reached, and probably never will reach, the standards of reliability and accuracy of electrical metering. The troubles experienced are largely mechanical; but there are certain fundamental obstacles in the way of their entire elimination. The operating conditions, because of excessive temperatures, moisture, and dirt, are severe, and the allowable size and cost of the meter are limited.

The meter first used in Detroit was of the tilting type, consisting of a rectangular pan of two compartments hung on knife-edge or ball bearings, the compartments filling alternately and, when full, tipping the pan so as to bring the opposite compartment to the filling position. In 1907 a revolving meter was devised, consisting of a drum of four compartments which filled and dumped successively, the drum being revolved by the weight of the water. This meter was fairly successful and a few of that design are still in use, but a greatly improved design of revolving meter, operating on the same general principle, (Fig. 6) was originated in 1909 by Hans Resert and is being used at present, with slight modifications.

Load Characteristics

The daily boiler-plant load curves vary considerably both in magnitude and in shape with different outdoor temperatures. In moderate weather steam is used in many buildings only for a few hours in the morning, resulting in a decided peak at that time with a steady decrease in load throughout the remainder of the day. On the very coldest days, however, the heat is used continuously throughout the 24 hours, in most buildings, giving a daily load factor on such days of between 85 and 95 per cent. This is illustrated in Fig. 7. The monthly sales of steam are very closely proportional to the difference between 70 deg. fahr. and the average outside temperature. The annual load factor is about 35 per cent.

The load curves of the individual buildings show these same general characteristics although different types of buildings have markedly different daily load curves. In Fig. 8 are shown the load curves of three buildings of different types. The high peak, in the case of the theater was caused by the throwing on of the fan system. The steam in the office building was shut off at night, while in the hotel it was used continuously.

Detroit rates at the present time take no account of varying load factor, though this is done in some other cities in an approximate way. Possibly future progress in the art of metering will lead to the general establishment of rate schedules having a demand component as well as a consumption charge.

Fire Engines and Effective Fire Fighting

By CHARLES H. FOX,[1] CINCINNATI, OHIO

The importance of the fire engine and the methods employed in fire fighting are frequently underestimated by both layman and engineer, and this is due in no small part to the fact that the principles involved are not sufficiently understood. In this paper the author presents the essentials of effective fire fighting and shows the important relation thereto of the fire engine.

A brief historical sketch of the development of the fire engine is first given, and performances and methods of rating fire engines, as outlined by the National Board of Fire Underwriters, are next presented. The paper concludes with a discussion of the losses in fire hose and the design of nozzle areas.

STEAM power was not successfully applied to fire engines until the beginning of the year 1853. Up to that time the so-called "hand engines" were used exclusively, and it should also be understood that at that time the present-day system of water works was still in its infancy and therefore the chief dependence for a supply of water was upon methods of storage in vogue before water mains came into general use.

The conventional hand fire engine of that day comprised a rectangular wooden box suitably mounted on four low wheels. Pumps of the piston type were housed within, and since at this early period fire hose was not plentiful (the best was crudely made up of leather), the pumps were therefore placed close to the scene of the fire. Water, largely conveyed by a hand-to-hand passing of fire pails, was poured into the engine trough, where it was picked up by the pumps and forced through the leading hose and onward to be thrown on the fire. Somewhat later it became customary to equip these hand engines with a non-collapsible suction hose, so that water could be drawn directly from cisterns or wells, but the wooden tub or reservoir always remained a characteristic feature of these old-time machines.

Early Steam Fire Engines

Early in January 1853, Mr. A. B. Latta successfully tested his new steam-driven fire engine. Mr. Latta was a citizen of Cincinnati, and, although his pioneer effort resulted in the production of an extremely heavy machine, the engine was purchased by the city and known as the *Joe Ross*. This first steamer marked the beginning of a new epoch in fire fighting.

The real basic element of Latta's invention was embraced chiefly in a quick-steaming water-tube boiler, dependent entirely upon a forced circulation of water through the steam-generating coils. The fire pumps were of an ordinary piston type. They were laid horizontally and occupied positions forward on opposite sides of the machine. Two steam cylinders, in alignment with the pumps, were placed so that the pump rods extended to the steam pistons;

[1] President Ahrens-Fox Fire Engine Co. Mem.Am.Soc.M.E.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. Contributed by the Cincinnati Section. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

while the steam piston rods, passing through the rear cylinder heads, were each coupled to a crosshead and by the use of connecting rods motion was communicated to the two rear wheels of the engine. This arrangement obviously provided means for propelling the apparatus under its own power. As a matter of fact, however, the *Joe Ross* and later engines of similar model were always drawn by horses, as the rear driving wheels could be disconnected from the engine and the pumping mechanism by means of clutches.

Mr. Miles Greenwood, another of Cincinnati's public-spirited citizens and prominent as a manufacturer, was at that time greatly interested in fire-department affairs. He was a staunch advocate of anything which would improve conditions, and to further his unselfish aims he took personal charge and became chief of the department, with the result that, within three months following the installation of the *Joe Ross* engine, the fire-fighting forces were completely reorganized under his leadership and the first paid fire department was inaugurated in the city of Cincinnati. The year 1853, therefore, also marks the beginning of the present paid system, and which has since been extended and generally applied to all large fire departments.

Latta's second steam fire engine was built and installed in the year 1853. The purchase of this machine was made possible by popular subscription, and the engine was named and long known in Cincinnati as the *Citizens' Gift*. From the begnning, Latta's new industry did not result in a monopoly, for rival steam fire-engine builders were soon in the field. Before tracing the further development which followed, it seems proper to refer briefly to the salient factors associated with fire streams and the fire engine.

Essentials of Effective Fire Fighting

It may first be stated that many of the methods employed by fire departments are not properly appreciated, either by the layman or the engineer. The importance of the fire engine is frequently underestimated and the possibilities of averting disaster are also undervalued, this being due in no small part to the fact that the principles involved are not sufficiently understood. There is therefore need for greater knowledge of fire prevention and fire fighting.

When fire must be fought, fire streams can be effective only when the water is expelled from the nozzle at an appropriate speed. In other words, unless enough of the initial pressure available for starting the flow through the hose survives at a point immediately back of the nozzle orifice, the resulting jet will not measure up to its mission. The characteristics of a fire stream—good, bad or indifferent—are directly dependent upon the velocity of the jet, and obviously the velocity is proportionate to the surviving pressure just mentioned. For the best results the flow may be too slow, while on the other hand disappointment will follow when the velocity of discharge goes beyond what might be termed the maximum economical limits of nozzle pressure.

It can be shown that little is to be gained by forcing nozzle discharges at much beyond 100 lb. pressure, and the proper remedy when only such high pressures are available is to substitute a nozzle of larger bore. On the other hand, if the jet seems to lag, it is an indication that the surviving pressure is not high enough to afford the required velocity of discharge, and under these circumstances if the initial hydrant or pump pressure is already at its highest possible point, or if it is also impossible to augment the volume of water passing, then the proper remedy is to substitute a nozzle having a smaller bore.

It may be of interest in this connection to note that the range of nozzle discharge pressures is not large between a stream of inferior reach and the swiftest jet within the economical power limit. While it is true that larger nozzles will "carry" farther at the same velocity than nozzles of smaller bore, yet for practical purposes it will be found that the most efficient fire streams are developed under the following conditions:

A jet issuing at a velocity under 60 ft. per sec. (about 25 lb. pressure) would not be considered a good stream. Above 60 ft. per sec. the jet stiffens, and as the velocity of flow increases the stream becomes the more effective. However, when the flow attains a speed of approximately 120 ft. per sec., with a corresponding discharge pressure of nearly 100 lb. per sq. in., a point is reached where additional forcing fails to contribute much in the way of added distance.

Fire-Engine Performance

The function of a fire engine is either to draw water from any basin or other conveniently located source, or, when fire hydrants are available to make up the pressure which is seldom high enough in ordinary water mains to serve for effective fire service. In fighting fire, it is not uncommon to elevate the nozzle far above the source of the water supply. This procedure, of course, involves loss of forcing pressure, which is in proportion to the static head of the column. The greatest power-absorbing medium between the source of supply and the point of discharge is the fire hose. It may also be said that here is involved the point which is least understood in the subject of hydraulics as applied to fire-fighting practice.

Fire-engine pump pressures must necessarily be kept within limits compatible with the strength of the fire hose, and when working pressures are maintained at upward of 250 lb. there is always considerable risk, because the average fire department is not always supplied with hose which will safely withstand the high pressures which modern fire engines are capable of developing. The initial pressure as indicated at the pumps drops off steadily toward the point of discharge, and it should be well understood that all pressure which is not thus absorbed by the friction of the flow through the hose is finally manifested as velocity at the nozzle orifice. Hence, unless the several factors that enter are considered together it cannot possibly follow that the best results will be attained.

The preceding paragraph expresses the gist of fire-engine performance, and the variable features always associated with the work may be definitely stated as follows:

Pumping Capacity: The number of U. S. gallons discharged per minute—

$\left.\begin{array}{l} a \text{ At 120 lb.} \\ b \text{ At 200 lb.} \\ c \text{ At 250 lb.} \end{array}\right\}$ pressure registered at pump.

Water Supply: The source and adequacy of the supply—

d If at draft—height of lift represented by the vertical distance of water surface below center of pump intake

e If at hydrant—capacity as indicated by pressure registered when water is flowing.

[Note: High static pressure, as indicated when hydrant is not flowing, is no index to its capacity to discharge any required volume.]

The Layout: Conditions affecting the discharge are—

f Size and character of the fire hose
g Number of hose lines in use
h Lengths of hose stretched between engine and nozzle
i Number of streams played
j Bore and style of nozzles used
k Elevation at the point of discharge.

During a long period manufacturers of fire engines were unrestricted as to the ratings which they assigned to their machines, and when "gallons per minute" were given, no definite discharge pressures were associated with the expressed pumping capacity. In pumping tests, the actual discharge was seldom checked or verified, with the result that comparisons of fire-engine performance were more a matter of guess than of accurate determination. This condition, however, no longer obtains, and the change is largely due to the exacting supervision initiated and persistently pursued under the auspices of the National Board of Fire Underwriters. A corps of expert engineers is constantly in the field for the purpose of investigating and keeping in touch with the fire-fighting situation in all cities, and pursuant to this policy of the insurance interests, it is now generally known what may be expected of fire engines when new and in prime condition, and periodical inspections disclose weaknesses subsequently developed in service.

According to the standards formulated by the National Board of Fire Underwriters in addition to the normal rating of a fire engine, expressed in gallons per minute, there must also be suffi-

cient power to expel the rated volume of discharge at a pressure of not less than 120 lb. per sq. in. Inasmuch, however, as certain situations may demand higher initial pressures, the pumps must also be so related to the attending power plant that higher pressures can be realized. Therefore further qualifications are demanded, as follows: One-half the rated capacity should be discharged by the pumps at 200 lb. pressure and one-third the capacity at 250 lb. pressure. Furthermore, fire engines should not be limited to 250 lb. pressure, for the fire departments of our large cities are confronted with the so-called "sky-scrapers," and when water must be forced to their upper floors, the overcoming of the static head alone greatly lowers the effective pressure.

However, when the power of an engine is fully utilized in forcing water to extinguish fire in a lofty building the work and the consequent strains are perfectly legitimate. On the other hand, when pressures much in excess of 250 lb. are employed simply to overcome resistance, which could be reduced by a more intelligent use of hose and nozzles, then the work evidently represents not only a waste of power, but also very bad practice.

Losses in Fire Hose

A good engineering axiom to observe is that all work should be accompanied with the least expenditure of force, and the aim here is to express the fact that many firemen have yet to learn how to smooth their own way. The point can best be illustrated by an example.

The inside diameter of fire hose ordinarily used is 2½ in. Cotton-jacketed, rubber-lined hose is the most common kind and lengths of 50 ft. (each such length constituting a section) are the recognized standard. The conventional way of expressing friction loss, or the loss pressure when water is flowing through the hose, is in terms of pounds per square inch for a unit length of 100 ft. for any given rate of flow stated in gallons per minute. This drop in pressure or so-called friction loss varies somewhat with quality or make-up of the hose; varying diameters and the fact that some makes of hose present a smoother waterway than others are also causes which prevent formulating a coefficient which can be applied to all kinds of 2½-in. fire hose and by which friction losses can be predetermined with precision.

It therefore follows from the foregoing statements that all tables setting forth friction loss in fire hose should be accepted only as close approximations, and in actual practice the results may therefore not agree. However, within the range of velocities and the lengths of hose ordinarily encountered in actual service, it has been found that for water flowing through 100 ft. of average good quality 2½-in. rubber-lined and cotton-jacketed fire hose, the friction loss will be about 14 lb. when the rate of the flow represents 250 gal. per min. Accepting this approximation as a basis, it must also be kept in mind that the friction loss increases in direct proportion to the length of the hose; hence, for the same rate of flow (250 gal. per min.) through 200 ft. the total loss would be twice as much as indicated for 100 ft.

The effect of varying the rate of flow follows a different and more intricate law, the friction loss increasing more nearly in proportion to the square of the flow. Therefore, if the loss per 100 ft. is 14 lb. when 250 gal. are flowing, it will be quite correct to assume that it will require nearly 2×2, or four times as much pressure, i. e., 56 lb. to discharge 500 gal. through 100 ft., 112 lb. through 200 ft., etc. Stated as a formula,

$$L = 0.00023G^2$$

where L is the friction loss per 100 ft. of 2½-in. rubber-lined, cotton-jacketed fire hose of good quality, and G is the flow in gallons per minute. The results obtained by using this approximate formula agree closely with those in the tables compiled by Mr. John R. Freeman, which appear in Fire Stream Tables, issued by the Inspection Department of the Associated Factory Mutual Fire Insurance Companies, Boston, Mass.

The red book, Fire Engine Tests and Fire Stream Tables, published by the National Board of Fire Underwriters, New York, gives the formula,

$$L = 2Q^2 + Q$$

in which L represents the friction loss, as before, and Q the volume flowing in gal. per min. divided by 100. Mathematical precision is always laudable, but in action firemen could hardly be expected to work out problems other than such as might readily be solved mentally. However, while extreme accuracy is entirely unnecessary in fire fighting, it would seem altogether feasible that fire engines could be set to work with hose layouts arranged with nozzles compatible with the general conditions of a situation, so that the efficiency latent in modern apparatus and appliances would be more frequently realized.

A close approximation, reasonably well gaged according to a correct and definite line of reasoning, is preferable to merely a guess or no system at all. Given sufficient study, the difficulties of apparently intricate hydraulic formulæ will vanish most surprisingly, and the real need today is for a greater cultivation of mental capacity to the end that commanding officers in the fire service become especially proficient in obtaining the best possible results with the apparatus at their disposal.

Nozzle Areas

It will be evident from what has been presented that the characteristic of a fire stream develops according to the following interlocking factors:

a The pressure which survives at the nozzle
b The volume of water reaching the nozzle
c The relation of the nozzle bore to *a* and *b*.

The difficulties which attend in the existing system of nozzle bores are largely due to the fact that the diameters vary after the order of ordinary machine-shop reamers, i.e., ⅞ in., 1 in., 1⅛ in., 1¼ in., and it therefore follows that the areas of the orifice have increments which increase in arithmetical progression.

A more logical system has long been proposed, wherein the nozzle orifices would be multiples of a fixed standard. In accordance with this method it was suggested that the 1¼-in. nozzle, a size now most common, be designated as "100 caliber." Other nozzles in the same system would be made with orifices of such areas that the water-discharging capacity at the same pressures would be respectively as the caliber number by which each is to be distinguished. Therefore, instead of nozzles measuring ⅝, ¾, ⅞, 1, 1⅛, 1¼, 1⅜, 1½, 1⅝, 1¾, 1⅞ and 2 in. in diameter, the caliber system would leave the ⅝- and 1¼-in. sizes as before, calling these 25 and 100 calibers, with others, to cover practically the same limits, but with fractional bores arranged in multiple, such as 25, 50, 75, 100, 125, 150, 175, 200, 225, 250, 275 calibers. Table 1 gives these proposed caliber values in more detail, and for a complete discussion the reader should consult Caliber of Fire Streams, Report of Transactions of the International Association of Fire Engineers, 1911.

TABLE 1 CALIBER SYSTEM OF STANDARD FIRE STREAMS

Devised and Proposed by Charles H. Fox

Caliber Value	Area, Sq. In.	Diam. of Bore, In.	Nominal Diam., In.
25	0.3068	0.625	⅝ Exact
50	0.6136	0.883	⅞ plus 0.008
75	0.9204	1.082	1 1/16 plus 0.019
100	1.2272	1.250	1¼ Exact
125	1.5340	1.397	1⅜ plus 0.022
150	1.8408	1.530	1½ plus 0.030
175	2.1476	1.652	1⅝ plus 0.027
200	2.4544	1.767	1¾ plus 0.017
225	2.7612	1.875	1⅞ Exact
250	3.0680	1.976	1 15/16 plus 0.039
275	3.3748	2.072	2 1/16 plus 0.010
300	3.6816	2.165	2⅛ plus 0.040
325	3.9883	2.252	2¼ plus 0.002
350	4.2951	2.337	2 5/16 plus 0.025
375	4.6019	2.420	2⅜ plus 0.045
400	4.9087	2.500	2½ Exact

Note:—The true basic caliber unit is the area of a circle ⅛-in. in diameter, viz., .012271875.

THE RETURN OF THE ELEVENTH ENGINEERS

After 22 months of service over seas the famous Eleventh Regiment of Engineers, which made a glorious record at Cambrai, returned to America, and on April 30 marched down Fifth Avenue in final review, 1300 men strong. Col. Wm. Barclay Parsons and his staff, accompanied by Lt. Col. William T. Chevalier, headed the parade and the regiment was reviewed by Governor Smith, Mayor Hylan and other prominent men. Following the parade a dinner was tendered by the Military Engineering Committee and thus was brought to a fitting close the career of the Eleventh Engineers in the Great War.

This is the regiment which was recruited by the Military Engineering Committee of the Engineers' Club of New York, with which in this effort the National Societies of Civil, Mechanical, Mining and Electrical Engineers coöperated. Recruiting began before war was declared, for the purpose of forming a reserve regiment of engineers, and the Eleventh Engineers proved to be the first step toward the organization of the National Army.

The deeds of the Eleventh Engineers have been followed with the greatest interest by engineers throughout the country and the following abstract of a recent article in the New York *Evening Post* by Col. Wm. Barclay Parsons gives a brief history of "the Fighting Engineers."

Sailing on the *Carpathia* from "an Atlantic port" in the middle of July, the regiment arrived at Plymouth and was promptly ordered to a camp at Borden, in the Aldershot district. On July 18, it was reviewed by King George, having the honor of being the first American unit to be reviewed by a King of England.

Our training at Borden began in the use of gas masks, but before the instruction was completed we were ordered to the continent, arriving at Boulogne the evening of August 7. From there we were ordered to Audruicq and finished our instruction in the gas school at Calais. We were then ordered south to Plateau, in the valley of the Somme, northeast of Peronne and to our regiment was assigned the task of getting the railroads there in improved physical condition, building sidetracks, which were intended later to receive fleets of tanks, and also to prepare for the reconstruction and maintenance of the Nord railroad from Peronne to Cambrai. All the territory had been in German hands but had been abandoned in the retirement of February and March, 1917, following the battle of the Somme, in the summer and fall of 1916.

When the Germans retired they had destroyed this road, blowing up bridges and removing the rails and ties. Part of the line to be reconstructed was in advance of the British guns; part of it was in view of the German first line trenches. It was imperative, however, that our labor attract no attention from the enemy. The work was done in scattered pieces—first in one spot and then another—and sometimes we worked at night.

While engaged in this work two of our men were wounded—Sergeant M. J. Calderwood and Private Brannigan. These men were the first American sodiers to be wounded in an engagement in France.

On our arrival at Peronne we were assigned to the British Third Army under General Byng. By the end of October we knew an attack was planned on Cambrai. This attack was not to be preceded by heavy artillery fire, according to past custom, but instead, there was to be a surprise advance by the fleets of tanks, which had been unloaded on the sidings the boys of the Eleventh had constructed.

Two weeks before the battle all conditions favored the British. The country was completely shut in every night by a dense fog, making it impossible for the enemy to detect our movements. All through the night the British moved forward with troops, guns, ammunition, and tanks. All was quiet in the daytime and the German aviators could find nothing.

The battle began on November 20. Six-thirty was the zero hour. The attack was successful beyond expectations. The Germans were completely surprised. By two o'clock on the same afternoon I personally was a mile and a half beyond the Hindenburg line. That night the attack had progressed sufficiently for our men to begin laying track on the roadbed they had already constructed. The Germans had abandoned their railhead and when the Americans laid rails up to the beginning of the German road there was connection between Paris and Berlin for the first time since 1914.

The British advance continued until November 22, when a heavy artillery duel took the place of infantry action. The British had gained 6 miles, had captured 11,000 prisoners, and had inflicted heavy casualties with slight losses to their own forces.

On the morning of the 30th the Germans began their celebrated counterattack. It was concentrated at two points, Moevres on the north and Gonzeaucourt on the south. The northern attack failed, but at Gonzeaucourt the British line was lightly held, and the Germans, acting as the British had previously without preliminary artillery warning, broke through in great masses.

Our men, suddenly surprised at their work, were without arms. The gray-clad German forces were seen rushing up the road. Hurriedly a miscellaneous force was gathered to stem the advance. Seizing picks, shovels, the few rifles they could find—anything—the Americans joined what British infantry was available. The defence soon took the form of hand-to-hand fighting, the Americans and British battling desperately to halt the Germans, greatly superior in numbers. While our resistance was not sufficiently powerful to stop the Germans, it did delay them and enabled the British to reconstitute the holding line.

We suffered heavily in killed, wounded and prisoners. It was the first real fight of the war in which American forces had taken part. The fighting continued severely all day. At night the British held and the Americans took positions in the back-line trenches in case the Germans renewed their offensive. Finally the British straightened their lines by giving up part of the territory they had gained and leaving our rail connection in German hands.

At the end of January, 1918, we were withdrawn and ordered to report for duty in central France in the construction of railway lines and yards. On March 21 the big German offensive began. The Allies realized it was a really dangerous attack, aiming to break through to the Channel ports and sever the British and French armies. The British asked General Pershing for two regiments of engineers. The 11th was the first to be selected.

On our arrival in the northern sector we were assigned to the First British Army under General Horne. Our first duty was to build trenches and other defence works just behind Arras, the British having laid out a very complete series of trenches, one behind the other, realizing that a further German advance would seriously cripple the lines of communication. The British program was to hold at whatever cost.

After a month we were moved further north, just south of Bethune, to engage in the same kind of work. During the two months we were there we built about 36 miles of complete trenches, 6 ft. deep, with fire-steps, machine gun posts, dugouts, tunnels, drains, and all other details of trench construction. We also put in place about 7 miles of heavy wire entanglements.

We were kept in this section until the middle of June, but the Germans failed to renew their offensive. Then we were moved south again. One battalion was posted below Chateau-Thierry to build an ammunition dump. The other half of the regiment was sent east of Issoudon for the same purpose.

At the end of August we were ordered to report to the chief engineer of the First Army to make reconnaissance for changing a meter gage railroad into a standard-gage line and for strengthening the bridges so they could bear heavier traffic. This line was just south of St. Mihiel, running from Commercy through the French lines, across No Man's Land to the German lines east of St. Mihiel, and north to near Verdun. So the regiment proceeded to Commercy. As in the Somme country in the previous year, we began working in small groups so as to attract the least attention. The line was rebuilt, following up the American advance with both ammunition and food.

On September 24 orders were received for half of the regiment, with headquarters, to go north and build a new railroad line down the valley of the Aire, through points which were then well behind the old German lines, the work to begin immediately following the opening of the attack. This attack is known as the Battle of the Argonne. Later, as the movement developed, more of the regiment was ordered to participate, being located north of Verdun. In this district we remained, improving communications which would facilitate further Allied advances, until the armistice was signed.

Before the Eleventh Engineers left France the general staff authorized the placing of five silver bands on the staff of the regimental colors, denoting as many major engagements, as follows: Cambrai offensive, Nov. 20-24, 1917; Cambrai defensive, Nov. 30-Dec. 3, 1917; St. Mihiel offensive, Sept. 12-16, 1918; Toul sector, Sept. 25-Nov. 11, 1918; Meuse-Argonne offensive, Sept. 26-Nov. 11, 1918.

Value of Government-Owned Machine Tools

Referring to the note in the April issue of Mechanical Engineering regarding Proposals for Technical Institutions to Obtain Government-Owned Machinery, in which through a typographical error it was stated that there are probably \$2,000,000 worth of these machines throughout the country, a member writes as follows:

At the Rifle Plant of the Midvale Steel and Ordnance Company, Eddystone, Pa., there were 11,000 machine tools which were government-owned, and placing the extremely low valuation of \$500 per machine it will be readily seen that there was more than \$5,000,000 worth of machine tools at this plant alone.

The American Brake Shoe and Foundry Company was given more than \$8,000,000 for its plant at Erie, Pa. Altogether there were approximately 300 plants which were Government-aided with "increased facilities" and it is doubtful if any of these plants received less than from two to three hundred thousand and many of them went into a million or several millions of dollars. This estimate applies only to army ordnance.

A rough estimate of the amount expended for machine tools to provide increased facilities for Government contractors is about \$250,000,000.

Mechanical Lifts—Past and Present

And Particulars Regarding a New Balancing Method in Which the Movements of the Supporting Elements Are Synchronized

By LIEUT. J. F. ROBBINS,[1] U. S. N. R., WASHINGTON, D. C.

In this paper the author first describes at some length the various types of mechanical and hydraulic lifts that have been developed for use in canal locks. He then gives particulars regarding a new type of lift in which the points of support of two counterbalancing loads are so interconnected that the movements of the supporting elements of the structure are synchronized and it is made impossible for the supports to get out of level. The advantages of this scheme and its adaptation to freight-car lifts, lifts for launching and dry-docking, and lift bridges, as well as to canal-lock lifts, are also brought out.

MANY types of mechanical lifts or elevators for lifting vessels over elevations have been proposed and built in the course of the development of waterways. However, the original principle involved in the masonry lock invented by Leonardo da Vinci still holds its superiority mainly because efforts to develop mechanical lifts have failed to keep pace with the increasing size of vessels to be transported.

The inclined railway for hauling the load up and over elevations by cable served its purpose, to a certain extent, in the early days of canal development, but had its apparent limitations.

A gated tank on wheels was built in 1874 on the Chesapeake and Ohio Canal, to be hauled up an incline by means of cables with counterweights, but failed in its practical application.

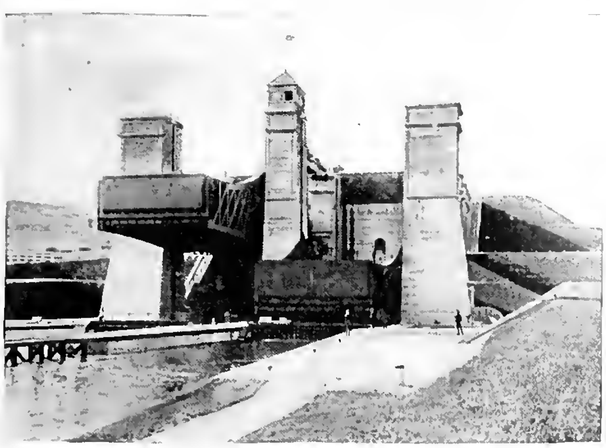

Fig. 1 Peterborough Hydraulic-Lift Lock, Trent Canal

In the same year, 1874, Edwin Clark, an English engineer, invented and built the first balanced hydraulic lift lock. This structure, built at Anderton, England, provided means for transferring vessels between levels of the canal on single plunger lifts.

Clark and his associates later built balanced lifts at La Louvière, Belgium, and Les Fontinettes, France, having a lift of 50 ft., the lock chambers being 140 ft. long and 19 ft. wide with a navigable depth of 7 ft. 10 in. He also proposed to use this principle for transferring trains of freight cars between different levels, but did not put the idea into practical use.

Canal Lift Developed in Germany

In Germany much work has been done in developing mechanical lift locks. Hoffman, a German engineer, invented and built a floating lock supported on tanks; and later, in the Dortmund and Ems Canal, locks were built on this principle, having a lift 68.5 ft. The lock chamber was built in the shape of a box with end gates 229.6 ft. long, 28.2 ft. wide and 8.2 ft. deep, supported on five steel cylinders or tanks. The weight of the structure and water load was supported by the buoyancy of these tanks, which floated in wells 30.17 ft. in diameter. The lift is made in approximately 15 min. by four large screws operated by 150-hp. motors. This installation, while larger than any mechanical lift previously built, fails to take advantage of the counterbalancing effect that obtains in the balanced lifts built by Clark. This necessitates a considerable expenditure of energy in overcoming the attraction of gravity which is, of course, unnecessary in any form of balanced lift.

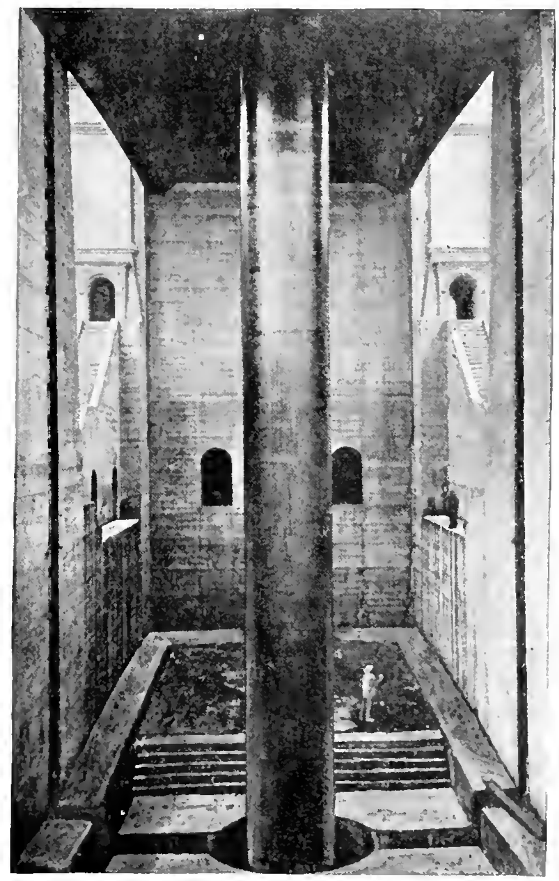

Fig. 2 One of the Plungers of the Peterborough Lock

The firm of Hoppe in Berlin has made a study of the application of a multiple of hydraulic plungers for operating large lifts, but found an insurmountable difficulty in maintaining the perfectly uniform and synchronous movement of a number of plungers which is absolutely necessary when handling loads greater than can be carried on one plunger.

Trent Canal Lift Locks

The largest and most successful example of the application of the balanced hydraulic lift was built in 1905 in Canada in

[1] Bureau of Steam Engineering, Navy Dept. Assoc.-Mem.Am.Soc.M.E.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

the Trent Canal at Peterborough.[1] This lock, shown in Fig. 1, together with the similar one at Kirkfield on the Trent Canal, has been in successful operation since put into commission and has various economic advantages over the masonry type of lock. The total lift of 65 ft.—over twice the height of the lift of the Panama Canal locks—has been made in the record time of 6½ min., the average time necessary to pass a vessel being from 10 to 12 min. Since only a comparatively small amount of water is used in making a lockage, most of the normal flow through the canal is available for water power, some of which is used for operating auxiliary pumps and lighting.

The lock at Peterborough consists of two steel boxes 140 ft. long, 33 ft. wide and carrying 10 ft. of water, each supported on its centrally located plunger 7½ ft. in diameter with a 65-ft. stroke. (Fig. 2). The cylinders or presses into which the plungers extend are connected by a 12-in. pipe with a gate valve, so that with one box with its water load at the upper level and the other at the lower level of the canal, by opening the valve in the cross-connection the position of the lock chambers is changed and the lockage made.

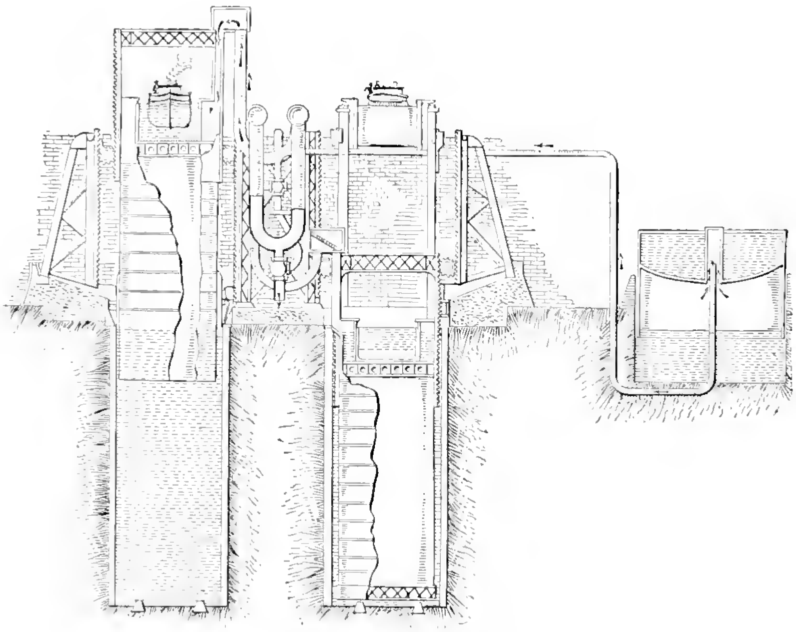

FIG. 3 AIR-SUPPORTED LIFT LOCK PROPOSED FOR N. Y. STATE BARGE CANAL

The stroke of the plungers has been set so that the box at the upper level stops with the water level in the box about four inches below the water level in the canal, and takes on this additional water load. This excess load, amounting to about 50 tons, when taken into the upper lock acts as a surcharge to overcome friction and gravity and bring the upper lock down and the lower one up.

When it is desired to transfer a boat from one level to the other, the boxes being in their respective positions at the end of the stroke of the plunger, the clearance between the end of each box and canal is first closed by inflating an air hose laid down the side walls and across the sill. Then this clearance space is filled through wicket gates in the end gates of the lock and canal. The clearance space having been filled and water levels in canal and lock having been equalized, the end gates which are hinged across the sill of lock and canal are folded down, making a continuous stretch of water from the canal to lock. Then the vessel is moved into the lock, displacing its own weight of water, of course, so that the load is constant, regardless of the size of the vessel. After the entrance of a vessel into one or both of the locks the end gates are closed, the clearance space emptied, and the cross-connection valve gradually opened, allowing the upper box to come down and forcing the lower one up.

While this installation of balanced lifts has proved to be economical in first cost, operation, time and quantity of water required to make a lockage, the locks are not large enough to accommodate vessels or cargo barges of very great capacity.

It was found, however, that the size and load to be handled were about as extensive as could be supported on the cantilever structure of the box over one plunger. Also, the total weight of one lock chamber, plunger and water load, which is in the neighborhood of 1900 tons, was about the maximum that could be safely supported on the masonry foundation for the cylinder castings.

For these reasons, and because no scheme has been found for safely supporting the load on more than one plunger, no balanced lift has ever been built of greater size than the one at Peterborough.

PROPOSED LIFT LOCKS FOR N. Y. STATE BARGE CANAL

A vertical lift lock was proposed for the Erie Canal at Lockport, N. Y., where a single mechanical lift was to take the place of a double flight of masonry locks there used to overcome an abrupt change in elevation of 56 ft. The design called for a steel box 225 ft. long, 29 ft. wide, and 9 ft. deep, which was to be supported by 88 link-and-pin chain cables attached to floor beams and running up and over sheave pulleys and down to 1000 tons of cast-iron counterweights. The sheave pulleys were to be carried by steel shafts supported, one on each side, in the permanent structure built at each side of the canal. The movement of the load was to be controlled by a number of brakes on the shafts.

At Cohoes, on the New York State Barge Canal, the installation of a mechanical lift lock was seriously considered, and a board of engineers investigated and reported on three different designs. Here, in the place of 16 masonry locks, it was proposed to install a pair of balanced lifts to overcome an elevation of about 120 ft. The specifications called for two counterbalancing tanks 310 ft. long, 28 ft. wide, and 12 ft. deep, each capable of floating two vessels of 1000 tons capacity. The three designs considered proposed to make use of three different supporting mediums; air, sets of cables, and hydraulically operated plungers.

Air-Supported Lifts. In the pneumatic design the weight of the steel box, or lock and water load, was to be directly supported on the elastic cushion of air maintained under the load by having the steel sides of the box extend downward below the surface of water maintained inside a large rectangular caisson built in the canal. See Fig. 3.

The two similar structures, either in tandem or parallel, were to have the air space under each box connected by huge air mains 21 ft. in diameter, with the necessary return bends and valves for shifting the supporting air from the space below one lock to the other when the locks were to be shifted between levels.

Cable-Supported Lifts. The second design considered by the board of engineers covered a pair of steel boxes of the specified dimensions supported by numerous cables running over sheave pulleys on the permanent structure from one box to the other, each load thus counterweighting the other and being shifted from one elevation to another by a surcharge of water in the upper box.

Plunger-Supported Lifts. The third proposal covered a pair of steel boxes working up and down in balance with each other and supported on three steel plungers under each load. The cylinders were to be connected by piping with suitable valves so that when the upper lock came down the lower lock would be forced up, registering with the upper level of the canal. As in the pneumatic scheme, it was recognized that some device for maintaining the level of the box would be necessary. In

[1] This lift has been fully described and illustrated in the *Scientific American*, July 7, 1906, the *Engineering Record*, March 30, 1907, and various other engineering publications.

this case the movement of the three plungers was to be coordinated by a central counterweight directly connected with both ends of the tank "in such a manner that the weight would always act to overcome the effect of any unbalanced load."

In this, as well as in the second proposal, the equilibrium of the structure and water load was to depend on the operation of a mechanical device, the positive action of which would be questionable for maintaining the level of an unstable water load.

The report of the board of engineers shows considerable interest in the future possibilities of the hydraulic plunger lift, but recommended four masonry locks with a lift of 28 ft. each.

Proposed Cable-Supported Lift Locks

An interesting design for a balanced lift lock has been described by Dr. J. A. L. Waddell[1], in connection with the proposed Lake Erie and Ontario Sanitary Canal and Power project. See Fig. 4.

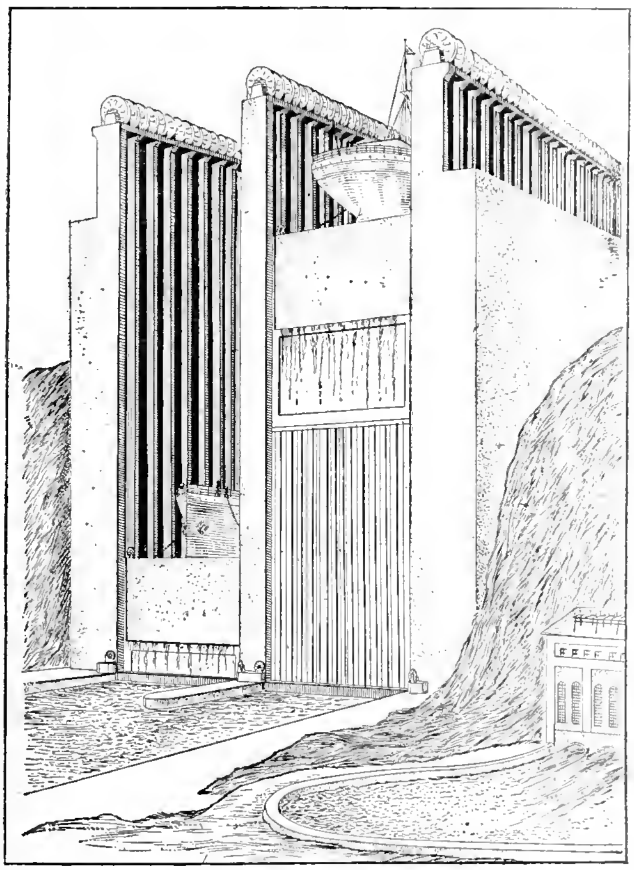

Fig. 4 Cable-Supported Lift Lock Proposed for Lake Erie and Ontario Sanitary Canal

Here, in order to make available for power purposes the water which would be used for lockage in the masonry type of lock, it is proposed to install two pairs of balanced lifts, one of 208 ft. and one of 104 ft. lift. The lifts, as described, are to be supported by cables connecting the inboard side of the two parallel boxes and running over fifty-six 20-ft. diameter sheave pulleys, mounted on the retaining wall between the boxes. The outboard edge of each box is connected by a similar set of cables running over pulleys and to counterweights suspended outside the two outer retaining walls.

This design, adopted as the most feasible *known* method of overcoming the high lift with locks of large size, is somewhat similar to that which was proposed for the New York State Barge Canal. It is believed that there would be considerable difficulty in maintaining the equilibrium of these lock chambers, which are to be 660 ft. long, 70 ft. wide, and carrying 30 ft. of water; and that some extensive braking apparatus would be necessary on the sheaves or supporting shafts. Any excess load on one end of one lock, tending to force it down, would lift the same end of the other up and would be cumulative in effect with the water load.

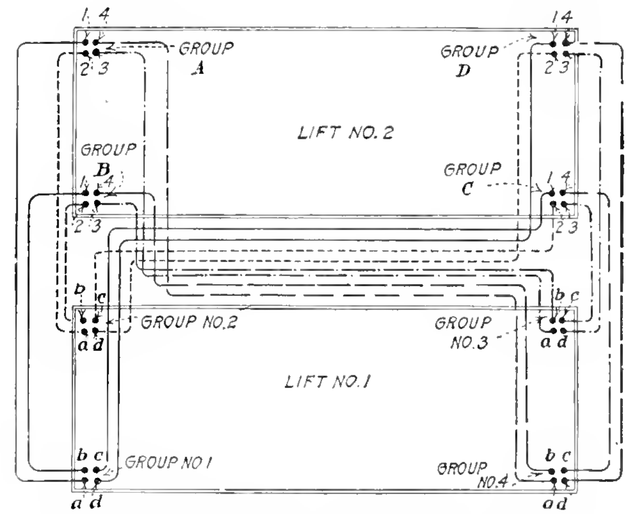

Fig. 5 Diagram Showing Connections for Harris Balanced Lifts

Lift No. 1: Plungers of Groups Nos. (1, 2, 3, 4) connected to plungers Nos. (1, 2, 3, 4) of Groups (A, B, C, D) of Lift No. 2, and conversely from Lift No. 2 each plunger of Groups A, B, C, D is connected to a similar plunger in Groups (1, 2, 3, 4) of Lift No. 1.

(Plungers of each group of one lift are hydraulically connected to the four corners of the other lift, so that the pressure due to one lift is uniformly distributed to the other, making it impossible for either lift to get out of level)

As has been well said by the inventor of one of the many designs of balanced lifts, "No mechanic has yet put into successful operation an apparatus in which a number of hydraulic plungers are so controlled and synchronized as to move at equal speed, as they must in operating a lock chamber."

This difficulty of synchronizing the movement of a number of supporting plungers has stood in the way not only of the development of hydraulic lifts of a size sufficient to meet the demands of modern canals, but also has prevented the use of balanced lifts in other applications where their use might be the means of solving urgent economic problems.

A Basic Principle Solving the Balancing Problem.

Through many years of study of this problem no feasible scheme has been proposed up to the discovery of the simple method of interconnecting systems of balancing plungers, or cables, as hereinafter presented.

This scheme virtually does away with limitations as far as size of the lift and load to be handled is concerned. The accompanying diagram, Fig. 5, illustrates this principle of interconnecting the points of support of each load. As indicated in the figure, each lift is supported by a group of four plungers (or cables) at each corner. The plungers *a*, *b*, *c* and *d* in group No. 1 of lift No. 1 are hydraulically connected with plunger No. 1 of groups *A*, *B*, *C*, and *D* of lift No. 2; plungers in group No. 2 of lift No. 1 are connected with plunger No. 2 of groups *A*, *B*, *C* and *D* of lift No. 2; plungers in group No. 3 of lift No. 1 are connected with plunger No. 3 in groups *A*, *B*, *C* and *D* of lift No. 2; plungers of group No. 4 of lift No. 1 are connected with plunger No. 4 of groups *A*, *B*, *C* and *D* of lift No. 2. Conversely, from lift No. 2, each plunger of groups *A*, *B*, *C* and *D*

[1] *Scientific American*, March 23, 1918.

is connected to a similar plunger in groups Nos. 1, 2, 3 and 4 of lift No. 1.

Thus the plungers of each group of one lift are hydraulically connected with the four corners of the other lift, so that the pressure due to one load is uniformly distributed to the other.

A simple illustration of a cable-supported lift of this type is shown in Fig. 6, in which two shelves are supported by 16 cords. In this model four cords are white, four are red, four are brown and four are blue and white twisted. In the figure the red and brown cords cannot be distinguished from each other.

To each corner of shelf No. 1, supporting the glass of water, four cords of the same color are attached, each cord passing through a screw eye directly above the point at which it is attached. The four white and four twisted cords can be followed in the figure from the corner to which they are attached, up through the screw eyes, across the frame, where one of each color passes through a screw eye over each corner of shelf No.

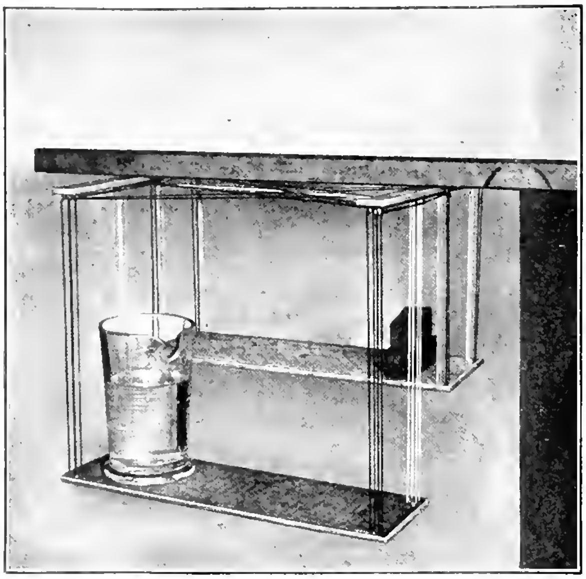

Fig. 6 Simple Model of Harris Type of Balanced Cable-Supported Lift

2 supporting the lead weights and finally down to each corner of shelf No. 2, where they are attached.

If pressure is applied downward on the corner of shelf No. 1 where the white four cords are attached, the other ends of these cords being attached to the four corners of the shelf carrying the weights, the latter shelf will be raised and will at all times be level. Also, since the red, brown and twisted cords are carried in the same way from the other three corners of the first shelf to all corners of shelf No. 2, no part of either shelf can move up or down without all parts of the other shelf moving an equal distance in the opposite direction.

Any part of either shelf will sustain loads equal to the full combined strength of the cords supporting that part.

The device is not limited to any one size or shape in securing these results. If the shelf is too long to carry the necessary load by the cords supporting it at the corners, a second group of cords can be attached to each shelf at any equal distance from the center of each shelf, carrying from each part of shelf No. 1 to each corresponding part of shelf No. 2, and duplicating the arrangement of the first set, these shelves can then be loaded to the combined strength of the 32 cords and at the same time practically divided into three sections as to their strength for carrying these loads. Then, if force enough to overcome the combined friction of all the cords be applied to either shelf, all parts of each one will travel up or down the same distance at the same time.

It is apparent that with the two loads supported in this manner, either by plungers below the lifts, or overhead cables, no load, up to the limit of the design of the structure, could force either lift out of its normal plane or level, however eccentrically the load might be placed. If it were desired to build a pair of lifts several hundred feet long, the total length would be divided into a certain number of spans required by economy of design, and the required number of similar systems of balancing plungers would be used and the various systems connected as shown in the sketch of a single system. Thus, by increasing the number of similar systems it would be possible to build lifts of practically unlimited size.

Freight Lifts

The utilization of the potential energy of one of two similar loads to shift them between different levels, has only been applied in a large way to the transfer of vessels in canals. But the foregoing illustrated scheme of supporting two such loads makes it feasible to apply the principle to other uses.

Clark's idea of transferring trains between different levels on single-plunger lifts may now be applied to the handling of freight between subway and surface levels, on lifts of sufficient size to carry any number of freight cars.

In view of the difficulty and expense of present methods of delivering freight, for example, into New York City by car ferry and the fact that no feasible method has hitherto been proposed for getting freight from subways to surface levels other than the hauling of trains up inclines or breaking freight below and lifting it on elevators of small capacity, this scheme is put forward as a solution to the problem of overcoming freight congestion.

With the increasing value of real estate, the use of large surface areas becomes prohibitive, making many floors above and below surface levels necessary. This scheme, applying balanced lifts to freight-terminal warehouses and points of distribution, would obviate present long hauls both by truck and train, and make it possible to utilize space to the greatest advantage.

For the handling of freight it would be advisable to design the lifts so that a certain load could be lifted up in excess of that coming down. This could be done by having a certain number of lifting plungers under each lift with a pumping plant of the necessary capacity to lift the e-cess load.

Fig. 7 shows a typical design of a freight lift for handling fifteen cars on each of two three-track bridge structures between subway and surface levels. After assuring the level and uniform travel of the lifts by a certain number of balancing systems of plungers, certain plungers of the remaining groups have their pipe connections led through a pumping plant for controlling and lifting excess loads.

While it is true that in less-than-carload-lot freight terminals the outgoing tonnage is usually two or three times the incoming tonnage, this capacity for lifting a certain per cent excess load would be advisable and methods of handling such incoming and outgoing freight would have to be so coördinated as to make use of the loads in so far as possible. The available portion of the potential energy of the excess outgoing tonnage might be used to advantage to lift occasional excess incoming loads by storing the excess energy in accumulators and using it to assist in elevating incoming tonnage.

Lifts for Launching and Dry-Docking

This principle may have a possible application in the field of shipbuilding in connection with the dry-docking and launching of vessels. For example, it might have been applied to advantage in the launching elevator recently built at the Ford plant for launching Eagle boats. In this installation two pairs of simple hydraulic jacks on each side of the platform are used to support the movable structure and boat and to lower the boat into the water. It is then necessary to pump the jack plungers and platform back up into position.

An elevator of this kind might be supported by groups of four plungers under each corner with a nearby counterweight to balance the weight of the platform, supported on an equal

number of plungers. With the plungers connected as described, there would be no possibility of their tipping or binding, of plungers, even though the platform were eccentrically loaded. The counterweight would bring the platform back up into position, without the necessity of a pumping plant or any power for control or operation.

Lift Bridges

This scheme may be applied to lift bridges where the span is too great for the use of the so-called "jack-knife" bridge. Here again the bridge structure could be supported by four plungers at each corner connected to four plungers under each corner of the counterweight situated under the roadway at one end of the bridge. The plungers under the counterweight might be two or three times the diameter of the plungers supporting the bridge, and so reduce the stroke of the counterweight to one-half or one-third of that of the bridge.

The same principle of interconnecting the points of support of bridge and counterweight may be applied with supporting cables instead of plungers. It is probable, however, that the plunger lift would be the most economical design as no heavy overhead truss would be necessary and the towers now used in counterweighted vertical-lift bridges to support the overhead truss, counterweights and motors could be made very much lighter, since these towers would only be needed as guides at each end of the bridge.

The movement of the bridge would be properly regulated by a train of throttling valves in the system of interconnecting pipe lines, and all operations would be governed by an interlocking system of automatic control.

Balanced Lifts as Applied to Erie and Ontario Canal Projects

While the lift of 208 ft. in the proposed lock of the Erie and Ontario Canal project is considerably higher than any existing plunger lift, it is within the range of the feasible application of a multiple of supporting plungers. Such lifts as are proposed, supported on plungers, would be absolutely positive in their relative movement and would have their equilibrium and level assured without auxiliary apparatus. Plunger lifts would render unnecessary the immense counterweights, the total weight of which has to be equivalent to the weight of one lock with its water load. By supporting the loads on plungers below the structure, the retaining walls, which support the sheaves and total weight of the locks, could be made very much lighter as they would be needed simply to act as guides to the movable structure. With these locks supported on the proper number of systems of balancing plungers, as determined by economical design, the groups of four plungers at several points in their travel upward would pick up guides to act as stiffeners similar to those used with long single plungers of passenger elevators. These guides would hang by chain or cable from the lock structure and would be provided with a loose collar for each plunger and guide in tracks in the side walls, thus breaking up the unsupported length of the plunger columns sufficiently to carry the load without bending.

In the cable-supported lifts described by Dr. Waddell it is proposed to use electric motors connected to the sheave pulley shafts for shifting the locks. Since the friction of the extensive cable system and the inertia of two such loads, estimated to be approximately 50,000 tons each, would be very great, this would entail a considerable expenditure of power. In view of this fact it would seem more economical to make use of a surcharge of water in the upper lock for shifting the locks, similar to the manner in which the Peterborough locks are operated. With the two loads supported on systems of balancing plungers, assuring perfect synchronism of movement, control in starting and stopping would be maintained by a train of simultaneously operated throttling valves in the various interconnecting pipe lines.

The proper sequence of events in the operation of such an installation, as a whole, would be governed by semi-automatic interlocking control systems under the supervision of one man, so there would be little possibility of anything going wrong.

Figs. 8 and 9 illustrate the hydraulic-plunger application of this principle. Fig. 8, a view of the underneath side of Model No. 3, shows the four pipes running from the four balancing plungers at each corner of one platform to the four corners of the other platform. Under the middle of each platform are two groups of four pump plungers connected to a common pipe through a small geared pump to the other platform. At the left end of the model is a small accumulator, with a hand pump, which can feed through a common pipe and check valve in each of

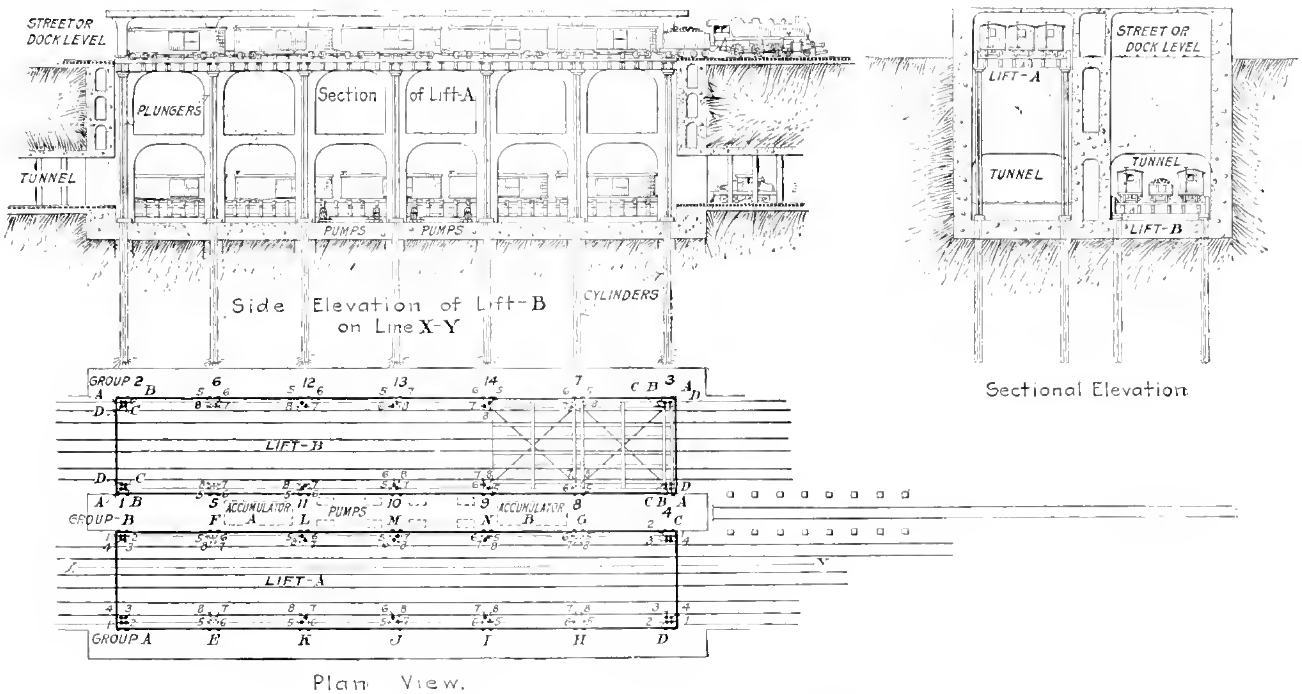

FIG. 7 TYPICAL DESIGN OF A HYDRAULIC BALANCED FREIGHT-CAR LIFT

the 16 small pipe connections between the balancing plungers. The accumulator is kept under sufficient pressure to feed through any check valve to replace leakage in any part of the system. Another train of check and throttling valves, one in each of the 16 interconnecting pipe lines—connects to a common pipe and back to the accumulator for throttling down the platform that happens to be in the upper position when it is desired to put the lift out of commission for repairs.

In the other view of Model No. 3 (Fig. 9) the pump plungers were secured down out of the way, and a load of two pigs

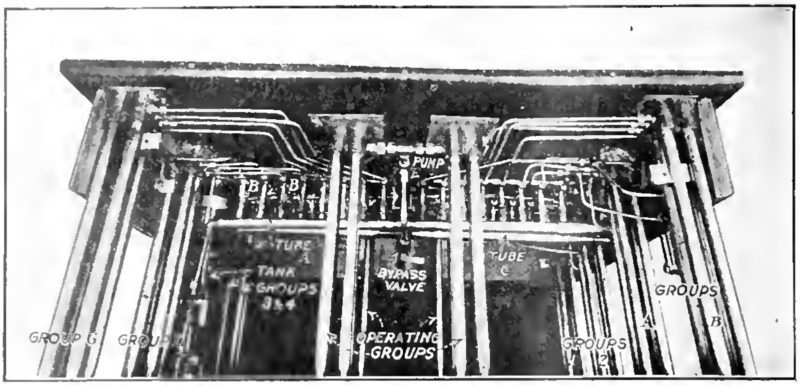

Fig. 8 View Underneath Model No. 3 of Harris Hydraulic Balanced Lift, Showing Plungers, Piping Connections, Etc.

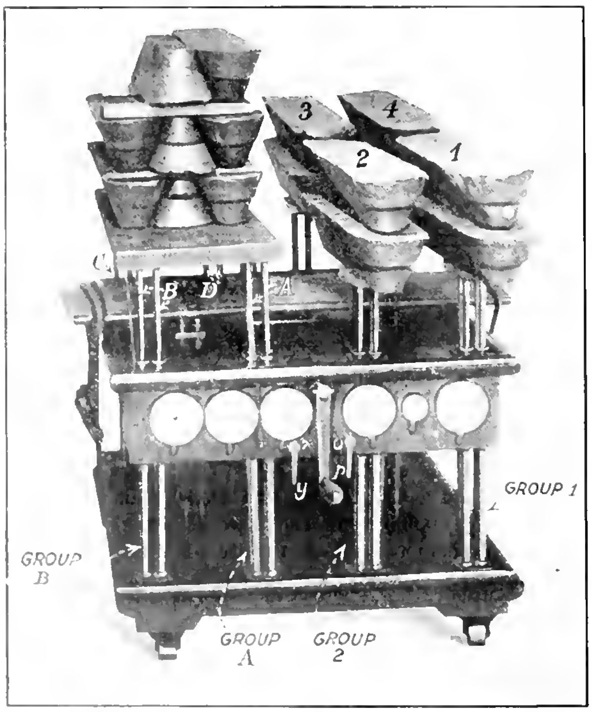

Fig. 9 Model No. 3 with Each Group of Plungers of One Lift Carrying Individual Loads, an Equal Load Resting on the Platform of the Other Lift

of lead was balanced over the cap of each set of balancing plungers. An equal load was placed on the other platform. With the model loaded in this way, it was possible to force down any one of the four groups of plungers by the pressure of the hand, when the other platform would rise and the remaining three groups of plungers would descend at the same rate; showing that no dependence was necessary on the platform structure for maintaining the level of the groups and that no strains would be produced in such a structure for maintaining the loads level. Moreover, when loads of 1200 lb. were placed eccentrically on each platform, the lifts remained level when moved up or down by means of the pump and pump plungers.

The gages on the front of the model were installed for the purpose of studying the various pressures. The first one on the right shows the accumulator pressure; the small gage indicates the pump pressures, and the remaining four gages are installed in the pipe lines from the cylinders of one group of balancing plungers.

In its application to canal-lock lifts this principle has no limit to which it may not be extended. It may be applied in the great canal systems being developed in Canada, and in the possible future canalization of the United States for ocean-going shipping. It has the very great advantage of economy of water necessary to supply the leakage of vessels. This feature makes it possible to build canals over territory where the rainfall over areas at summit levels is insufficient to supply the water necessary for lockage in the old masonry type of lock. This matter of taking the water supply now used for water power for use in proposed canal systems has alone been a considerable item of cost of proposed waterways.

While this scheme of interconnecting points of support of two loads, as described, has been granted basic patent rights and some little work has been done in the design and development of models and in anticipating the many engineering problems involved, no application of it has yet been undertaken.

It is believed, however, that by the development of this principle of so connecting the points of support of two counterbalancing loads as to synchronize the movement of the supporting elements of the structure and make it impossible for the loads to get out of level, its inventor, William Thomas Harris, of Chicago, has solved an important mechanical problem and has opened a way to the future development of waterways and to more efficient methods of handling freight.

The shipment of 50 locomotives without the use of lighters was recently accomplished directly from Erie Railroad Pier H at Weehawken, N. J., into the holds of the single-decked ocean freighter *Feltore*. The work was done with the standard pier equipment, and no special preparations were necessary. Direct loading of vessels had never been attempted before because of the well founded impression that damage to fixed equipment would result, which is based on the fact that in many ships the hatches do not have sufficient area to permit free passage to packages of large dimensions, with the result that forcing methods in loading have had to be resorted to. That is to say, large packages often became wedged in the hatchway, and when pried loose would drop and shift quickly, setting up strains sufficient to break rigid equipment. As the hatches of the *Feltore* extend across the ship for almost its full width, no difficulty of this nature had to be overcome while loading it directly, and the operation proved to be a complete success.

The 50 locomotives were delivered unassembled to the pier in 200 cars. The car loads were made up of 20-ton locomotive boilers, 14-ton tender tanks, 12-ton locomotive frames, 4-ton cabs, 4-ton drivers and 3-ton cylinders. During the first day 19 of the 20-ton boilers were loaded in seven hours, a cycle being completed in about 22 minutes.

Following usual methods, the ship would have been anchored off shore and the cargo moved from the pier by cranes, loaded on to barges, and from these transferred to the hold of the vessel by the usual lighterage methods.

As the cargo could not be loaded on to barges in less time than is required to load it into the ship, the initial saving by the method of loading directly into the ship is apparent. The time which would be required to transfer the load from the barges to the ship would depend on the location of the ship in reference to the pier and cannot be arrived at definitely. As a comparison, however, it may be said that the estimated time for transferring a 20-ton locomotive boiler from a barge to a ship is about one hour as compared with the 22 min. mentioned. (*Railway Age*, April 18, 1919)

The Status of Industrial Relations

By L. P. Alford,[1] New York, N. Y.

At the Annual Meeting of the Society in 1912, a report was presented by the Sub-Committee on Administration, of which the late James M. Dodge was Chairman and L. P. Alford Secretary, on The Present State of the Art of Industrial Management. This report was replete with information upon the broad aspect of the management problem as it then existed in the industries of the country.

During the seven years which have intervened since the preparation of this report, the question has been studied from many different angles and has come to be viewed in quite a different light from that in which it was regarded when the original report was prepared. In consequence, the Committee on Meetings and Program appointed Mr. Alford a committee of one to prepare the following new report upon the subject for presentation at the Session on Industrial Relations at the Detroit meeting.

This report not only comprises a review of the new aspects of the problem which have recently developed, but also a historical summary of the progressive stages in the development of industrial relations since the period immediately following the Civil War. It has proved to be inevitable that after any great economic disturbance like that produced by the Civil War, or the present period of unrest following the world conflict in Europe, there should be unrest and uncertainty in the field of labor and employment; and it thus seems appropriate at this time to outline briefly the most important transactions which have occurred in this field, beginning with the time of the Civil War and including the situation which now exists, so similar in character, but greatly amplified.

IN the presidential address made to this Society in 1882 is the following remarkable statement of the responsibility of engineers in solving the problems involved in the relations of employers and employees:

> In singular and discreditable contrast with all the gains in recent and current practice in engineering, stands one feature of our work which has more importance to us and to the world, and which has a more direct and controlling influence upon the material prosperity and the happiness of the nation than any modern invention or than any discovery of science. I refer to the relations of the employers to the working classes and to the mutual interest, of labor and capital. It is from us, if from any body of men, that the world should expect a complete and satisfactory practical solution of the so-called "Labor problem." More is expected of us than even of our legislators. And how little has been accomplished.

Dr. Thurston was speaking of conditions as they were a full generation ago, yet his words are as true today as they were then. The world is looking to the engineers for leadership in these matters "and how little has been accomplished."

The topic of industrial relations is so complex and far-reaching that any treatment within the space of a professional paper must of necessity be restricted to certain aspects of the problems. So in attempting to outline the present position of the body of fact that is comprehended in the term "industrial relations," the scope will be limited to a survey of the more important developments of the last thirty or thirty-five years, and to a statement of a few of the more outstanding tendencies revealed by events of the immediate present.

Before we can attempt to outline the status of industrial relations it is necessary to define what we mean by the term. To that end this statement is offered:

> *Industrial relations comprises that body of principle, practice and law growing out of the interacting human rights, needs and aspirations of all who are engaged in or dependent upon productive industry.*

[1] Chief of Staff, *Industrial Management*. Mem. Am. Soc. M. E.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the pages are available to the members gratis upon request. All papers are subject to revision.

It will be observed that this definition does not include directly the feelings of uneasiness and unrest among industrial workers, but views them as the expression of real, or fancied, rights or needs, and considers strikes and lockouts as but the assertion of the same or similar claims. On the other hand, the definition does include not only the interests of employers and employees who are actually engaged in industry, but likewise of others who are dependent upon productive industry for the satisfaction of some of their needs, or for the safeguarding of some of their rights.

Beginning with about 1880 there were developed and put into use two practices expected to mitigate or help solve the labor difficulties of that time, namely, profit sharing and methods of wage payment intended to give the worker a direct share in the benefits of increased production. At the present time we are seeing another heightening of interest in profit sharing and the widespread installation of the so-called shop-committee system. Thirty years ago and today are similar periods of experimentation in industrial relations.

Although the beginnings of the development of industrial relations took place during the 80's of the last century the situation in industry did not become acute in the United States until about 1905. That date fixes approximately the time when the evils of absentee directorate of large corporations came into prominence. Many of our great industrial consolidations had taken place before 1905 and the owners had put into effect a system of control and management arbitrarily determined in a few of our large cities, principally New York City, while the plants of these corporations were spread throughout the country.

It is frequently stated that the necessity for establishing industrial relations today is the growth of the factory system wherein all personal contact is lost between owner or manager and the worker. While this is true, it does not sum up the entire loss. In the system of absentee directorate there are other evils as well, and these taken together have set up situations where there have been clashes over the rights, needs and aspirations of those who belong to the class of employers and those who form the great group of employers. These losses in fitness for control may be stated in this wise:

a The loss of personal contact and relationship that formerly existed between the master and his skilled workmen and apprentices

b The loss due to the lack of personal knowledge of the work being done on the part of present-day directors and managers

c The loss due to the lack of personal knowledge of the tools and equipment used in production on the part of present-day managers

d The loss of the direct oversight of saving and conserving materials and human effort on the part of present-day managers

e The withdrawal from productive work of the families of the directors and managers

f The loss of equality of living conditions between the families of the directors and managers and the workers.

The effect of these losses in creating a situation where there may be a clash of interest, and failure on each side to understand and appreciate the other, is brought home when we contrast the human relationships in the days of craftsmanship with those of the factory system. In former time the employer or master knew how to do all parts of the work himself, had in fact done so with his own hands, was in personal contact with all of the tools, equipment and materials used in his shop, had complete personal oversight of everything that was done, and held a relationship of almost father to son with his apprentices who, in many cases, lodged and boarded in the master's home and were served by the master's wife and daughters. Not only did the master instruct his ap-

prentices in the requirements and skill of the trade, but he likewise set them the example of right living. All of the activities of the master opened to the apprentice as he became able to exercise them. There was a complete community of interest between the master and his family, his workmen, their families and his apprentices.

By contrast, in American industry today far too often the owners and directors live hundreds and thousands of miles away from the workers in their plants, under entirely different conditions, as varying as New York City and a Massachusetts mill town or a Middle-West factory community. All exact knowledge one of the other is lacking, there is no community of interest or purpose, and no assurance that a policy determined upon in the directors' room will meet the needs and rights of the workers in some far distant locality.

It is the creation of this situation of absentee directorate that has done much to focus attention upon the necessity of developing a body of principles, practice and law to satisfy the needs and safeguard the rights of all who are engaged in or dependent upon American industry.

Examination reveals six major lines of development amid the various methods, plans and systems that have been tried in seeking to work out better industrial relations. These are:

a Profit-sharing plans
b Methods of wage payment
c Methods and laws to reduce the hazards in industry and mitigate the effects of injuries and also of occupational diseases
d Employment management
e Declaration and enforcement during the period of war of three rights of workers, namely, collective bargaining, restricted hours of labor and the living wage. Declaration of these same rights and others in the Treaty of Peace.
f Systems for mutual or joint control by employers and employees.

A controlling reason for considering these six lines of development is their actual or promised permanence and widespread acceptance and application. For this same reason it does not seem pertinent to the purpose of this paper to devote space to welfare methods, industrial betterment, suggestion boxes or systems, shop gardens, factory bands, dances, minstrels, glee and athletic clubs, employees' loans, benefit associations, pensions and many other activities that properly classify under our definition of industrial relations. Without doubt successful applications of every one of these activities can be mentioned, and likewise, without doubt, experiences can be pointed out where they have had a beneficial effect in promoting satisfactory conditions and assisting to develop a "spirit of the organization." It is more than likely that many of these activities will always find a place in industry, but none of them seem to be a major line of development, and in fact all classify under welfare work or industrial betterment, which have fallen into disrepute because of the motive of charity or paternalism that has inspired them in many places.

The element of failure in all these agencies is the lack of removal of the fear of unemployment. For the fundamental cause of industrial unrest is the dread of losing the opportunity to work and thereby secure the necessities of life, or of being cut off from deserved promotion.

Profit Sharing

Profit sharing has been mentioned as one of the lines of development that became prominent during the period ending in 1889. A few of these were mercantile establishments, but all were large employers of labor.

Not only is there reason to believe that these attempts were inspired by conditions of industrial unrest, but there is direct testimony to this effect in two cases. The Globe Tobacco Company, of Detroit, Mich., entered into an agreement in regard to its profit-sharing plan in 1886 with the district board of the Knights of Labor; and the plan of the H. O. Nelson Company, of St. Louis, Mo., which was announced on March 20 of that year, was an outgrowth of the great railroad strike, strikes in the building trades and the movement for the eight-hour working day.

Within the past six months a number of large industrial plants in this country have announced or put into effect profit-sharing plans, so we seem to be having a repetition of what took place during the 80's of the last century.

It is worth while to point out that although profit sharing was put into effect in a number of American industries a generation ago, it has never had widespread adoption. This fact may cause us to question its effectiveness as a promoter of good industrial relations. Several reasons are recognized for this situation: Payment of gains under profit-sharing plans are deferred and so lack an immediate appeal; the gains do not come directly nor entirely from the efforts of the workers, but are dependent upon the hazards of the enterprise; the amount distributed to any individual worker is equivalent to an increase of only a few cents an hour for the year; the amount shared by each person among the owners and managers is many times greater than that received by each workman.

Plans for stock participation have the same purpose and value as those for profit sharing.

Methods of Wage Payment

The pioneer work that has since yielded the science and practice of industrial management was performed during this same period of industrial unrest, that is, from 1880 to 1889. During this decade Mr. Henry R. Towne presented two papers before this Society that have been frequently referred to as the beginnings of the literature of industrial management. The first was read in 1886. In it Mr. Towne called the attention of his fellow-engineers to the need of a study of the financial and profit-making aspects of shop management. He urged his associates to become "economists" because the engineer is one who essentially effects economy. His second paper was presented in 1889 and in it was described a gain-sharing plan that Mr. Towne had applied in his own shop. The object was to enable his employees to share the profits of the business depending upon gains in efficiency as shown by careful accounting.

Influenced by his study of the epidemics of strikes during the same decade, Mr. F. A. Halsey originated his premium plan of wage payment that was disclosed to this Society in a professional paper read at the Providence meeting in 1891. A recent letter written by Mr. Halsey to the author mentions the activities of the Knights of Labor and the great street-car strike in New York City as two of the events that influenced him to study the possibility of some form of wage payment that would reward the worker for increased effort and production.

This same decade was the period of the work of Dr. Frederick W. Taylor, which later on gave to this Society several papers outlining his system of shop management. It will be recalled that a part of his methods was a system of wage payment known as the "differential system."

Since that time several other methods of wage payment have been originated and developed, so that today we recognize some half a dozen that have more or less extensive application. Each one has been developed with the purpose of improving the relationships between employer and employee in regard to the division of the earnings and profits of industry, or to provide an extra reward for extra productive effort.

The "Safety-First" Movement and Workmen's Compensation

About 1910 American juries began to award large sums in suits for personal damages, where the plaintiff had been injured by machinery or otherwise in industry. Employers turned to liability-insurance companies to defend these suits and settle with their employees, thus bringing an outside party between them and their workers. Appreciation of the hazards in industry and the hardships endured by incapacitated workmen and their families, not only during the period of recovery from the injury itself but perhaps throughout the life of the wage earner due to decreased

earning power, gave rise to the "safety-first" movement and the enactment of workmen's compensation laws.

It is interesting to note that the safety-first movement was fostered largely by men residing west of Pittsburgh, many of whom were in the employ of large corporations where directorates were in New York City. Furthermore it was from the outset a young man's movement. Here and there a few progressive firms paid generous compensation voluntarily before laws were passed making this practice compulsory. Mr. John L. Henning instituted such a plan in 1904 in a mining operation in Louisiana of which he was chief engineer. This is the earliest attempt of this kind in the United States that has reached the author's attention.

In the enactment of compensation laws the rights and needs of the community were recognized. An entirely different view of the legal relationship of employer and employee was taken than that which had existed before, and which was summed up in the expression "master and servant." The responsibility for the injuries was placed squarely upon the industry through the employer, and in boards and commissions, machinery was set up to make sure that employees would receive the compensation to which they were entitled. The leader among the states having compensation laws is New Jersey and the effective date was July 4, 1911.

But the safety-first movement has yielded much more than this group of legal enactments. There has grown up a large body of practice in regard to safeguarding machinery and working spaces, establishing and operating first-aid rooms and factory hospitals, toward improving the heating, ventilation and sanitary conditions in factories, removing or mitigating conditions tending toward occupational disease, providing medical, dental and nursing service for the families of employees, establishing medical examinations before employment and at stated intervals thereafter, teaching personal hygiene to employees and their families, and, in fact, a complete new outlook in regard to the health and physical welfare of all who are engaged in industry. Through it all there has been a moral motive.

The movement has also brought into being two strong organizations, the National Safety Council and the Workmen's Compensation Bureau. In addition there is an association of physicians who are engaged in industrial practice.

The American Society of Mechanical Engineers has contributed to this development through taking the initiative in preparing several safety codes or standards. It is estimated that the safety-first movement of the past ten years has reduced the number of annual fatal accidents in the United States from 35,000 to 22,000 with a corresponding lessening of maiming and disabling accidents. This line of development is the most significant of all from the viewpoint of the interests of the community.

Employment Management

Since 1916 there has come into prominence what is now recognized as a new profession in industry, that of employment management. It comprehends in its broadest interpretation the establishment of all policies and direction of all of the functions having to do with personnel. It has taken over, expanded and developed the former work of hiring and discharging, has sought to reduce labor turnover and has fostered and directed those activities which are usually comprehended under the term welfare.

The oldest organized employment department of which the author has knowledge has been in operation about nineteen years in the plant of the B. F. Goodrich Company, Akron, Ohio. In 1907 Mr. H. F. J. Porter in a discussion of a paper presented before this Society called attention to the evils of labor turnover and outlined some methods that he had taken for its reduction. In 1914 Mr. Magnus W. Alexander presented a striking address before a convention of the National Machine Tool Builders' Association in which he gave statistics gathered from some twelve metal-working plants revealing the tremendous amount of the turnover of labor and its excessive cost. A small group of men in and around Boston, Mass., worked on this problem of employment for a number of years and as early as 1910 organized the Boston Employment Managers' Association.

But the movement did not gain headway until about 1916 when it was ready for the truly marvelous expansion that has taken place during the period of the war. No other line of development in industrial relations has had the rapidity of growth of employment management. But the impelling motive has not been entirely that of fostering good industrial relations, although that result has come in many cases where the work has been well done. The major reason in the minds of most industrial executives in establishing employment departments has been to secure employees during the period of labor scarcity and to find out why men leave. Another impetus to the movement came through the action of the United States Government in insisting that such departments should be installed in plants manufacturing munitions, war supplies and ships. To meet the demand for trained managers a number of colleges and universities established six-week courses in employment management under the direction of the War Department. Since the signing of the armistice several of these have been modified and put on what will probably prove to be a permanent basis.

Declared Rights in Industrial Relations

As a war measure President Wilson by proclamation created a National War Labor Board to establish principles and policies in regard to the employment and utilization of labor during the period of war, more particularly in war industries, and to set up machinery for considering and adjusting grievances. At the outset this Board declared three rights of labor: The right to organize and bargain collectively; the right to a limited number of hours of labor; the right to a living wage. The Peace Treaty written at Versailles recognizes these three rights and several other principles that are of "special and urgent importance." The recognition of these rights is a great step in the development of industrial relations, and they can never be abrogated in American industry. The same situation is reflected in British conditions as shown by the report of the Employers' Industrial Commission of the United States Department of Labor.

Mutual or Joint Control

The sixth major line of development has to do with control in industry. Students of the present condition of unrest have pointed out that the fundamental is a "struggle for control," the opposing forces being the owners and the workers. The expression "industrial democracy" is frequently used as describing a state that is about to come, or is now being ushered in. The parallel between our political democracy and the expected industrial form is sometimes put in this wise: The slogan that gave birth to this nation and brought our political democracy was, "No taxation without representation." The parallel slogan expressive of the movement to bring industrial democracy is "No control without representation."

The method that is being followed to put this ideal into practice is the shop committee. It is a new development. The oldest was put into effect in 1903 and most of them were started in 1918. Bridgeport alone has 44 plants where this system is in force. The plan installed by Mr. H. F. J. Porter in 1903 in the plant of the Nernst Lamp Company in Pittsburgh was described by him in an article published in *The Engineering Magazine* in August 1905. The shop committee was made up of secretly elected employees under the chairmanship of the shop superintendent. Conditions in the plant that might be bettered for the employees were discussed, and the committee evidently functioned as a safety-first committee as well as a representative shop committee.

Without doubt the success of the safety committees, with which there has been some six or seven years of experience, has paved the way in many plants for the representative shop committee. In fact, a prediction of this development is found in a paper presented before this Society in 1915 written by Mr. W. H. Cameron.

A general classification of these shop committee plans yields three types:

The first sets up an organization roughly paralleling the Cabinet, Senate and House of Representatives of the United States

Government. The Cabinet may consist of some or all of the directors or higher executives of the plant. The Senate may consist of all or a portion of the foremen, while the House of Representatives is a body secretly elected by the employees.

A second type divides the workers in the plants into divisions, each having a definitely determined and equal number of employees, not necessarily defined accord to craft or occupation. Any one division may include employees from several trades and doing varying kinds of work. Each division secretly elects its own representative, and these representatives coming together form the shop committee. This plan is simple, but is not adapted to industries where there is a high degree of organization or where the workers naturally divide into a series of recognized trades.

The third plan is the one adopted by the National War Labor Board and installed under its direction in a number of plants making war materials. Its essential features are outlined in the following official statement of procedure for election:

> Shop committees shall be selected to meet with an equal or lesser number of representatives to be selected by the employer. Each department or section of the shop shall be entitled to one committeeman for each one hundred employees employed in the department or section. If in any department or section there shall be employees in excess of an even hundred, then an additional committeeman may be elected providing the additional employees beyond the even hundred shall be fifty or more; if less than fifty no additional representation shall be allowed. As an example: In a department or section employing 330 men, three committeemen will be elected; in a department employing 375 men, four committeemen will be elected.

In plants where shop committees have been in operation for some time, a wide variety of topics has come up for discussion and determination. One grouping lists some forty-two different kinds of matters, of which only one was wages. The plans are too new, however, to estimate the extent of the effect they may have in developing good industrial relations. But a sufficient amount of experience has already been accumulated to indicate that the application of the ideas of joint consideration and control on the part of employers and employees will produce favorable results. To reach a workable basis, the employer must voluntarily limit his own authority and agree to conduct his business by the rule of reason and even-handed justice as interpreted by the representative shop committee that he may set up. The plan seems to restore, so far as possible in a large-scale business, the simple and effective relationship that used to exist between the master and skilled workman, and which largely exists even to-day between the small employer and his half-dozen employees.

A rather more formal mechanism for establishing representation in industry is the protocol system worked out in the coat and suit trade in New York City, and which has been applied in a few other instances in similar trades.

From one viewpoint the rapidly developing movement to put shop committees into effect in the United States is a confession on the part of employers and those who have the responsibility for industrial enterprises that they have already lost some of their control. Under such condition there is a readiness to experiment. From another viewpoint it is an earnest attempt to find a basis of democratic coöperation in the control of industry.

A parallel movement has taken place in Great Britain leading to the proposal to establish Industrial Councils through which the British Government may promote effective coöperation between the organized employers and workers, believing that representative government in industry will foster good relations.

DEVELOPMENT OF MOTIVES

After having sketched these six lines of development in improving industrial relations and in building up a great body of principle, practice and law, it is wise to examine some of the predominating motives.

One that came into play early and brought to the front those practices and activities summed up under the headings welfare work and industrial betterment was the motive of altruism. The successful manufacturer, taking the part of the autocratic benefactor, enjoyed the swelling of the heart and feeling of personal gratification that came to him when he arranged for the spending of money to provide conveniences and benefits for his employees, as bathrooms, restaurants, flower gardens, reading rooms, rest rooms, and the like. But workers are quick to resent favors if they are substituted for justice, and the welfare movement as such has very properly been discredited and has practically disappeared, although many of its activities have been retained but inspired by a different and proper motive.

The safety-first movement from its inception was influenced by engineers who saw the essential economy in preserving the life and limb of the workers. The employers translated this engineering economic viewpoint into the commercial motive "it pays." Selfish though this was and is, nevertheless it was neither charitable nor paternalistic, and because the movement had a firm basis in sound industrial economics and in morals it has met with deserved and widespread success.

But even this engineering-commercial motive is inadequate to provide the impetus for the developing of the industrial relations that we all hope for. It does not comprehend the interests of all who are dependent upon and must be served by productive industry; so many of the leaders of thought on industrial matters have declared and emphasized another motive, saying that it must predominate and prevail, else we will never have the development that we need. This is the one of *service*. A recent magazine article by Mr. H. L. Gantt clearly presents this motive. Once it becomes active we can hope for the working out of a new body of principle and practice in regard to industrial relations that will bring far happier conditions than any we have yet experienced.

INTERESTS IN INDUSTRY

With this development of motive has been a broadening of the recognition of those who are interested in the proper carrying on of industry itself. In the early days the expression "master and man" or the legal "master and servant" summed up these interests and relationships, but as industry developed and the clash of rights, needs and aspirations became apparent the familiar term became "capital and labor," used more particularly to denominate antagonistic forces. In fact, this term is used very generally at the present time, although it has been pointed out that there can be no conflict between capital as such and labor, for we cannot conceive of a man fighting with accumulated wealth represented in the physical means of production. So, to clarify thinking, some authors have insisted that we should use the term "capitalists and laborers" instead of capital and labor. Point is given to this contention by a quotation from a speech delivered by President Lincoln before the Wisconsin Agricultural Society in 1859: "Labor is prior to, and independent of, capital —in fact, capital is the fruit of labor, and could never have existed if labor had not first existed. Labor can exist without capital, but capital could never have existed without labor."

The next development of interests brought consideration of the needs and rights of the public, which depends upon the proper carrying on of industry for much of its well-being. This thought brought a new grouping—"capitalists, laborers and the public." Quite recently in studies of industrial relations some writers have included five parties, namely: The capitalists who supply the materials and means for production; the laborers who supply productive capacity; the managers who provide direction and control; the community in which the industry is located and upon whose operation its welfare to a certain extent depends; and the public that purchases the articles and goods produced.

There is more than ample reason for including the interests of the community and public in any such classification. The laws regulating the hours of labor for women and children, for the elimination of hazards in industry, and for compensation for industrial accidents are but one expression of the rights of the community as well as the worker in the operation of industry.

Before justice can be framed in the form of law there must have been developed a body of general principles. It is evident that the principles underlying industrial relations are now in a process of rapid formulation. It is probable that before long our courts will have to pass upon an increasing number of industrial-

(*Concluded on page 556*)

Production of Liberty Motor Parts at Ford Plant

By W. F. Verner,[1] Detroit Mich.

The Liberty motor was designed for quantity production and consequently many interesting methods were developed to speed up the work. Those employed in producing cylinders in six operations are particularly unique and this paper gives a brief account of the process as carried on at the Ford Motor Company's plant at Detroit during the period November 1917 to December 1918. A description is also given of the twenty-one operations necessary to produce connecting-rod crankshaft bearings, and in the complete paper will be found details regarding the method of installing crankshaft bearings in the upper and lower halves of the crankcase.

On November 22, 1917, the Ford Motor Company entered into a contract with the United States Government to build 5000 Liberty motors. The contract was accepted at a time when Ford cars were being manufactured at the rate of 3500 per day and to change over from their production to that of Liberty motors was by no means a minor undertaking. The manufacture of Liberty motors differs in many essentials from the manufacture of the ordinary type of motor used for automobiles, and of the 14,000 tools used on Ford car production only 987 were adaptable to the production of Liberty motors.

It was estimated that 350,000 sq. ft. of floor space would be required to produce 50 Liberty motors per day of eight hours. The ultimate space required was 550,000 sq. ft. As no floor space was available, this necessitated the dismantling and removing of several thousand machines and the rearrangement of over 50 per cent of the regular plant equipment. The new arrangement was so made as to allow an entire building for the production of Liberty motors. This permitted the concentration of production and therefore maximum efficiency and production in the shortest time, and since production in the shortest time possible was the great issue, no expense was spared in this shop rearrangement.

The shifting of labor from standard-car production to Liberty motor production was gradual. No labor trouble was experienced as the curtailment in regular products released enough labor for the production of Liberty motors. Table 1 shows the growth in the number of men employed in the Liberty Motor Department.

TABLE 1 SHOWING GROWTH OF FORCE BUILDING LIBERTY MOTORS AT FORD MOTOR CO. WORKS

Date	No. of Men Employed	Date	No. of Men Employed
Nov. 22, 1917	0	Aug. 1, 1918	7,976
Feb. 2, 1918	675	Sept. 5, 1918	9,390
March 1, 1918	779	Oct. 1, 1918	10,653
April 1, 1918	1,550	Nov. 1, 1918	11,288
May 1, 1918	2,450	Dec. 1, 1918	826
June 1, 1918	3,412	Jan. 2, 1919	543
July 1, 1918	5,141		

In accordance with the terms of the contract deliveries were planned as follows:

April 1918	200
May 1918	800
June 1918	1000
July 1918	1000
August 1918	1000
September 1918	1000
Total	5000

This schedule was subsequently revised with instructions from the Government to attain a maximum production of 100 motors per day in anticipation of an order for 7000 additional motors. The schedule was revised to obtain a production of 2500 motors per month by December 1918.

Production was fast approaching the goal when the armistice was signed, as evidenced by Fig. 1, which shows the production of Liberty motors at the works of the Ford Motor Company for the period from November 1917 to December 1918. As is invariably the case in any new undertaking, the production of these motors was retarded by many factors which it was the effort of the engineers to eliminate. Among the predominating ones were the following:

1 Orders for raw material could not be placed immediately on account of incomplete detailed specifications
2 There were many changes. For a period of 14 months, 1013 changes were authorized: March 1918 showing 167, April 109 and May 115; then tapering off to December 1918 which showed only eight changes. These changes represent Government changes and do not include those made by Ford Motor Company in dies, jigs and fixtures, which averaged from three to five for each of the above

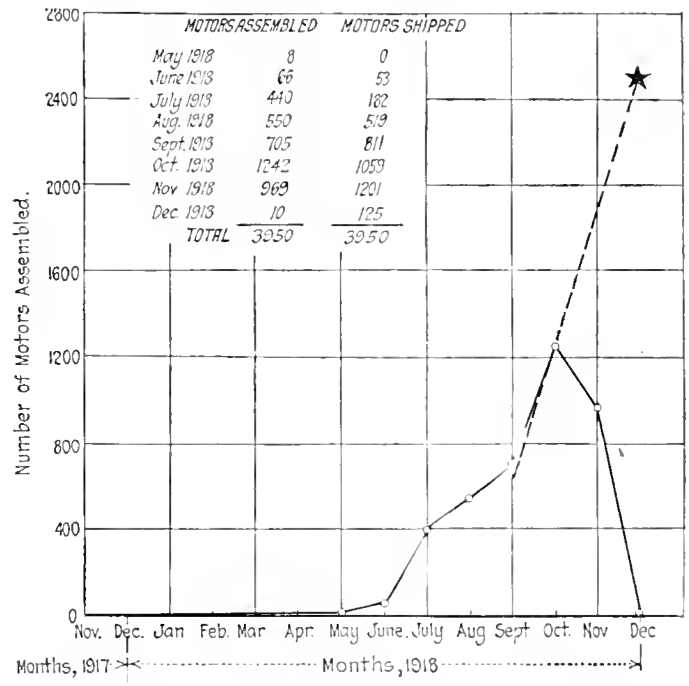

Fig. 1 Production of Liberty Motors at the Ford Motor Company's Plant

3 Material specifications were constantly revised
4 Shortage of fuel, especially with sub-contractors
5 Railroad embargoes delayed shipment on shop machines and raw materials
6 A-4 priority on shop machinery instead of A-1
7 Lack of acceptable thread gages
8 Lack of actual shop experience by Government inspectors.

The falling off in production in November was of course due to the signing of the armistice. On the day the armistice was signed, the highest mark was reached in the number of motors assembled in one day, namely, seventy-five.

Method of Producing Motor Cylinders

Several major and important developments were brought about by the Production Department of the Ford Motor Company. First among these was the cylinder forging made from tubing.

[1] Mechanical Engineer, Ford Motor Company, Detroit, Mich. Mem.Am. Soc.M.E.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. Contributed by the Detroit Section. The paper is here printed in abstract form and copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

This method resulted in an enormous saving when considering the cost of machining a cylinder from a solid forging and also the cost of making a solid forging. The Liberty motor cylinder was forged from a high-carbon steel tube $5^3/_4$ in. outside diameter, $4^3/_4$ in. inside diameter by $39^3/_4$ in. mill length, and completed in six operations as follows:

Operation A—Cut off
Operation B—Close head
Operation C—Form the head
Operation D—Rough-drill bosses for inlet- and exhaust-valve ports
Operation E—Upset and form flange
Operation F—Heat-treat.

Operation A—Cut Off. The tube was heated, at the point at which it was to be cut to about 1200 deg. fahr., in a specially

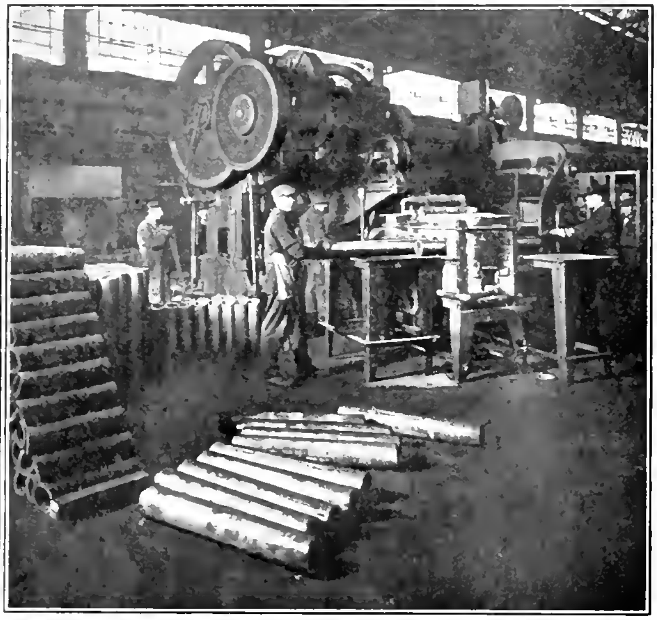

FIG. 2 GAS FURNACE FOR HEATING TUBES—OPERATION A

designed rectangular gas furnace having a series of circular openings along two sides, and through which the tubes were inserted. The capacity of the furnace (Fig. 2) was such that the successive tubes were heated sufficiently for cutting within the time required for the cutting operation. Once started, the operation was continuous with a production rate of 150 tubes per hr. per machine.

Upon removing the tube from the furnace it was placed in the shearing die of a press equipped with a special punch and die. The tube was then fitted with an arbor so constructed that as the punch of the press sheared the outer wall of the tube, the arbor transmitted the shearing power to the lower wall, thus shearing the whole without distorting the tube. The punch and die were set on the press so that the end of the tube was cut at an angle of 19 deg. with the center line of the tube, to the required length of $20^5/_8$ in. at one side of the angle and $19^1/_8$ in. at the other side. This angular cut was essential to Operation B.

Operation B—Close Head. It was considered for a long time next to impossible to forge a Liberty motor cylinder from a tube on account of the manufacturing difficulties encountered in closing the head. When the end of the tube to be closed was cut at right angles to the center line, it was found unsatisfactory due to cold shuts or unfused sections in the metal occurring in the center of the dome.

However, by cutting the tube at an angle of 19 deg. with the center line of the tube it was found that the forming dies could be so constructed as to cup or draw inward the tube wall, the high or extended portion of the wall causing the converging or closing of the metal to one side of the center line of the tube until, in the final forming of the head, the metal was joined at right angles to the 19-deg. cut (See Fig. 3.) After this operation the appearance of the closed end resembled the common type of explosive shell with the nose portion at an angle of 19 deg. The central portion of the dome is thus formed without a weld and retains to the fullest extent its fibrous strength.

The angular head of the tube was then heated in a furnace similar to the one previously described to about 1900 deg. fahr. preparatory to forming the head so that the point could be used as a part of the boss which later was drilled for an intake or exhaust post.

The die used in this operation was of the double-action type and comprised two semicircular steel jaws, tapered on the upper outside diameter and pivoted in the rear to swing horizontally. A cast-iron locking plate was attached to the blanking foot of the press and tapered to correspond to the taper of the jaws, so that when the blanking foot was in down position the tapered surfaces of the jaws served to lock the tube in position. The interior upper parts of the jaws were bored and fitted with split bushings or bronze bearings to fit the punch. Resting flush normally with the upper surface of the jaw was a semicircular steel supporting band equipped with three guide pins supported on springs.

When the jaws were swung in position around the tube, they formed a steel ring which gripped the tube around the top or heated portion and as the punch descended, the ring slipped down the tube, and the supporting springs depressing under the pressure of the punch thus prevented the tube from bulging when the punch closed in the head. The punch was designed so that the dome was drawn to a point 19 deg. to one side of the center line of the tube, as previously described.

Operation C—Form the Head. This operation was performed on a press (Fig. 4) provided with a specially designed punch and die. To serve as a die, a bolster or base plate was mounted on the bed of the press. The base plate was bored in the center to re-

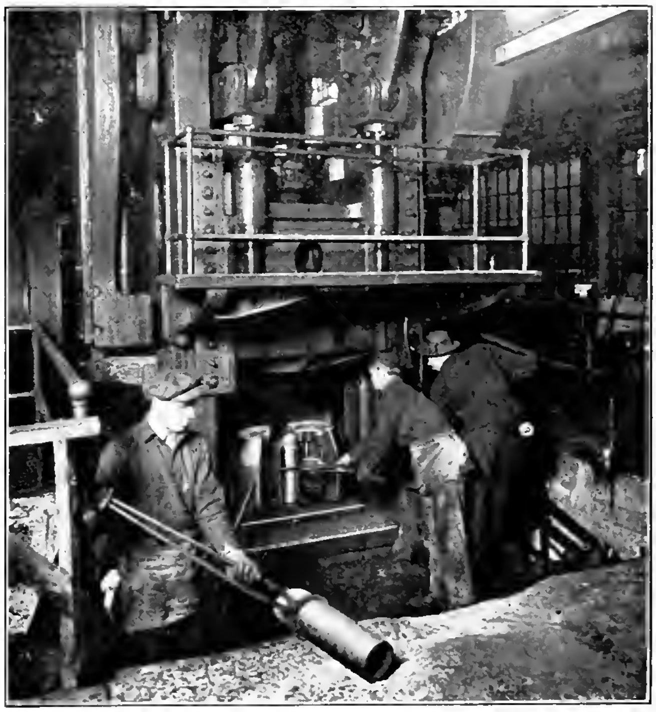

FIG. 3 PRELIMINARY FORMING OF THE CYLINDER HEAD—OPERATION B

ceive the shank end of an upright cylindrical locating arbor and counterbored to receive a thrust plate. Two sections made up the arbor, the lower of which was made of soft steel bored to receive the hardened-steel tip or top section. The top section tapered slightly inward at the extreme end and the top surface was curved to properly form the dome or head of the cylinder.

Horizontal sliding jaws around the locating arbor were held open by springs and operated by cams attached to the ram of the press. The upper interior portion of the jaws was shaped to form the expanded area for the combustion chamber. When the jaws were closed by the cams, they fitted snugly around the punch.

As the ram descended, the cams attached thereto forced the jaws together so that as the punch pressed down the head of the tube on the arbor it formed the valve-port and spark-plug bosses and the jaws formed the expanded area for the combustion chamber. On the back stroke, the jaws were forced apart by the springs as soon as the pressure of the cams relaxed. In case of adhesion to the cylinder, a wedge attached to the ram and operating between the two ends of the jaws breaks the adhesion on the back stroke. A knock-out sleeve located about the base of the arbor and operated by an arm beneath the bed of the press on the back stroke was carried upward and loosened the cylinder on the arbor. Production on one machine totaled 150 per hour.

Operation D—Rough-Drill Bosses for Inlet- and Exhaust-Valve Ports. The cylinder was held in a trunnion fixture attached to a drill press so that the center line of the valve port swung in line with the spindle. The cylinder was located by using the valve-port bosses.

Operation E—Upset and Form Flange. These operations were performed on a 5-in. forging machine in one heat-treat on two separate dies. The die used for the first portion of the operation (upset) comprised two horizontal sliding steel jaws operated by cams and bored at both ends to fit tightly about the body of the cylinder. At the middle the jaws were undercut or recessed so that in the upsetting the metal would so flow as to form a heavy ring of metal at the section at which the flange was to be located on the cylinder. The punch was in the form of a mandrel with a shoulder which fitted the closed jaws and which on striking the bottom of the skirt or open end of the cylinder forced the heated metal to the proper upset dimensions about the mandrel and in the recess of the jaws.

The die employed in the second portion of the operation (form flange) was of the same type above described, with the exception

Fig. 4 Press Used in Final Forming of Cylinder Head—Operation C

that the jaws were counterbored at the entrance end to the forged flange dimensions, instead of being recessed in the middle. The punch consisted of a mandrel with a shoulder surrounded by a sleeve which extended beyond the shoulder. The sleeve fitted the closed jaw of the die and the inside extended portion upset the metal by pressing it against the die, thus forming the flange. The sleeve was provided with two vent holes permitting gases that might be formed during the forging to escape.

In operation the skirt of the cylinder was first heated to about 1900 deg. fahr. in a furnace, then dipped in water to a depth of about 1½ in. This cooling was done to form a ring of hard metal at the bottom of the skirt for the punch to act upon. The cylinder was then placed in the forging machine and the flange made. Production totaled 85 per hour on one machine.

Operation F—Heat-Treat. The completed forged cylinder was placed in a large rectangular heat-treating furnace and heated to a temperature of 1525 deg. fahr. and then quenched in a brine solution. After quenching it was heated in an annealing furnace to a temperature of 1125 deg. fahr. and cooled in air. Brinell test was 217-255. This heat treatment left the cylinder ready for the machine operations.

Method of Machining Connecting-Rod Crankshaft Bearings

Next in importance to the method just described of producing Liberty motor cylinders was the development of a special process of making bronze babbitt-lined bearings for the crankshaft end of

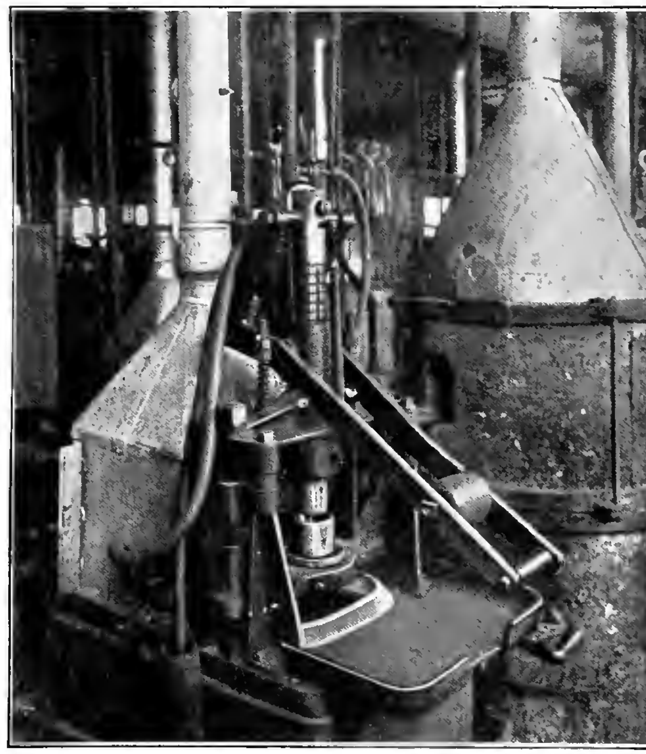

Fig. 5 Babbitting Machine—Operation 4

connecting rods which would stand up under the Government's 50-hour test. The method comprised 21 operations, as follows:

1. Rough-drill closed end
2. Rough- and finish-bore bronze and face one end
3. Turn outside diameter to fit babbitting fixture and face one end
4. Babbitt
5. Cut off gate, rough- and finish-bore babbitt
6. Finish-turn outside diameter to 3.095 in. and face ends to length
7. Press in broaching ring
8. Broach hole to 2.4275 in. in diameter
9. Press out of broaching ring
10. Grind outside diameter to 3.075 in.
11. Cut in halves with 3/64 in. saw (2 on)
12. Close in
13. Swage
14. Finish-mill the parting line
15. Face ends to length
16. Fillet both ends
17. Cut two grooves for forked-end rod
18. Drill and ream dowel holes in lower half bearing only
19. Cut two ⅛-in. semicircular oil grooves on the parting line
20. Cut twelve oil pockets in both halves
21. Burr.

Operation 1—Rough-Drill Closed End. A 21-in. drilling ma-

chine was used in this operation, which was necessary only on castings where a thin web of metal entirely closed one end.

Operation 2—Rough- and Finish-Bore Bronze and Face One End. This operation was performed in a 12-spindle 14-in. multiple machine. The bushings were gripped in a chuck and bored at the rate of about 80 per hour.

Operation 3—Turn Outside Diameter to Fit Babbitting Fixture and Face One End. A 12-spindle 14-in. multiple machine was also used for this operation. The bushings after boring were clamped on special arbors and the outside diameter turned to fit babbitting fixture.

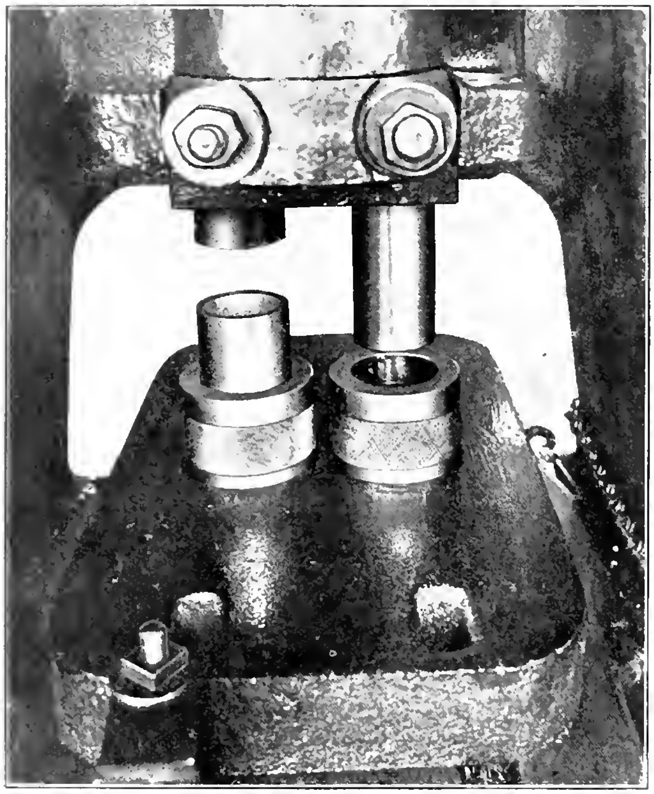

FIG. 6 PRESSING IN BROACHING RING—OPERATION 7

Operation 4—Babbitt. The equipment required for this operation consisted of acid vats, tinning furnaces, die-casting machines with water circulating systems, a furnace large enough to supply a unit of four die-casting machines with molten babbitt and a compressed-air outfit to use with the gas furnaces.

The bushing was first dipped into a flux made proportionately of 11 lb. sal ammoniac, 9 lb. zinc chloride, 6 qt. muriatic acid and 13 qt. water. The hydrometer reading was 23 to 25 deg. B.

Before placing the bushing in the specially designed die-casting machine to be babbitted it was immersed in the molten tin. The die casting machine, Fig. 5, consisted of a rectangular plate mounted on suitable legs or base, having a cored hole for receiving a crucible containing the metal; a crucible with suitable rim having two bosses on which were fitted bearings for a pump-lever shaft; a pump fastened to two bosses of the rectangular plate for forcing the metal through a nozzle into the die proper; and a fixture mounted on the plate straddling the pot for casting the bearing.

The fixture for casting the bearing was made up of a circulating water cooled mandrel or arbor sliding vertically in a housing. This housing was secured to two side support brackets which were bolted to the plate. The lower die holder carrying the die spans the crucible and slides vertically on guide pins. Springs received the weight of the holder in suspension. Just inside of the guide-pin bearings and screwed into the holder were two suitable rods which extended through the housing. The housing was drilled and counterbored to receive rods and springs. The lower die holder in its normal or loading position was suspended on the springs so that the opening or gate of the die was slightly above the nozzle of the pump.

For babbitting, a tinned bushing was inserted in the lower die and the water-cooled arbor was moved downward until stopped by the arbor stripper ring, clamping on the upper end of the bushing to be babbitted and the gate end of the lower die on the pump nozzle. The movement of the arbor was controlled by an upward movement of the hand lever. While holding the arbor firmly in position with one hand, the operator with the other hand pulls upward on another hand lever attached to the pump lever, thereby forcing the molten babbitt from the pump cylinder through the nozzles and into the bushing.

The metal was allowed to set for about 30 sec., when the pump-control lever was pushed downward. The piston of the pump upon its return uncovers ports permitting molten metal to flow into the cylinder preparatory to another casting. Simultaneously the arbor-control lever was thrown downward, assisted by the weighted end, causing the arbor stripper ring to strike violently against the lower face of the arbor housing and thereby stripping the babbitted bushing from the arbor. This upper movement of the arbor allowed the lower die holder to regain its normal position

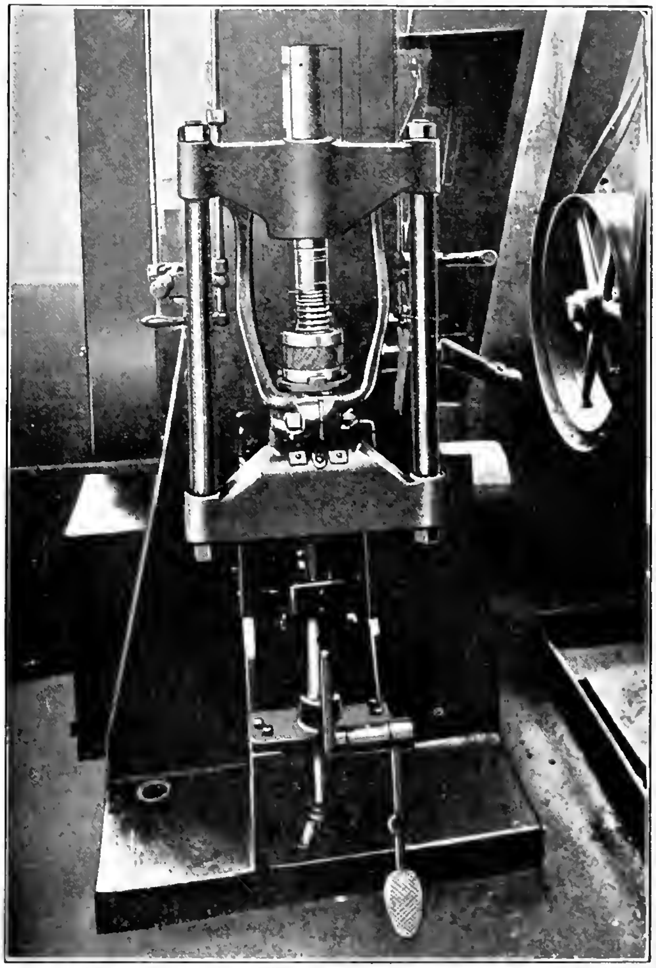

FIG. 7 SPECIAL BROACHING MACHINE—OPERATION 8

and severed the connection between the lower die and pump nozzle, which assured the bushing sticking to the water-cooled arbor and not becoming gate-anchored to the lower die. The thickness of the babbitt wall at the top for best results in babbitting was 3/32 in. and for the bottom 3/16 in.

Operation 5—Cut Off Gate, Rough- and Finish-Bore Babbitt. Geared-head screw machines were used for this operation. The bushing was held by a three-jaw clutch; an ordinary cut-off tool held in the tool block of the cross-slide was used for cutting off the gate, and a boring bar with two cutters (one for roughing and one for finishing) was mounted in the turret for boring hole to proper diameter, with an allowance for broaching.

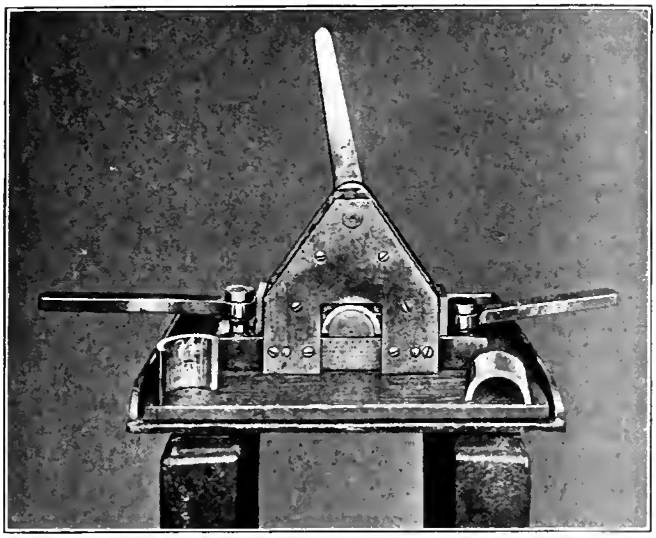

Fig. 8 Machine for Bending Bearings—Operation 12

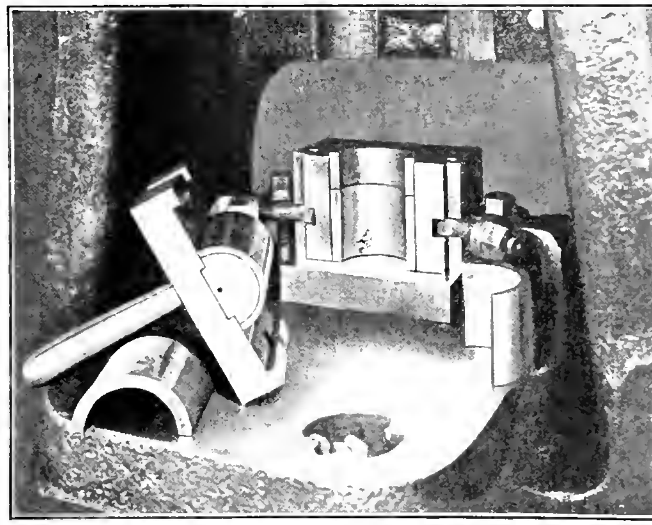

Fig. 9 Upsetting of Bearings to Finished Dimensions—Operation 13

Operation 6—Finish-Turn Outside Diameter to 3.085 In. and Face Ends to Length. In this operation 14-in. x 4-ft. lathes with back-arm attachments were used. The bushings were held on an expanded arbor, which was held in the spindle of the machine. A cutter mounted in the tool block of the lathe cross-slide turned the outside diameter to fit the broaching ring. The back arm carried a tool block with two cutters spaced to face the bushing to its proper length.

Operation 7—Press in Broaching Ring. For this operation (see Fig. 6) a bolster plate with two holes bored large enough to allow the bushing to drop through and counterbored to suit outside diameter of the broaching ring was strapped to the bed of a press. In the ram of the machine were carried two cylindrical punches slightly smaller in diameter than the outside diameter of the bushing but differing in length.

In operation a ring into which had been pressed a broached bushing was placed in the counterbored hole under the long punch and a bushing that was not broached was slightly entered into an empty ring and placed under the short punch. When the press was tripped, the long punch forced the broached bushing out of the ring and the short punch forced the bushing, which had not been broached into the ring.

Operation 8—Broach Hole to 2.4275 In. Diameter. A special broaching machine, Fig. 7, was designed for this operation. The legs were removed from a No. 1 Knowles keyseater and the body complete with gears, rack, slide, etc., was bolted in a vertical position to a special base casting. An upper guide of cast iron, with a hardened and ground steel bushing for the broach-holder quill was dovetailed to the ways of the machine. Below this upper guide was the extended work-holding bracket (a part of the bed of the Knowles keyseater) which carried the work holder. This work holder was a hardened steel bushing ground on its outside diameter to fit the hole in the bracket and counterbored to fit the broaching ring. On the special base casting below the work-holding support was bolted the lower guide, a gray-iron casting with a hardened bushing ground to fit the broach holder. The broach holder was a long tool-steel bar hardened and ground on one end to fit the guide bushings and on the other end to fit the holes in broach and broach-holder quill.

The foot-pedal bracket was bolted to the base of the machine and was bored to fit the broach holder to which it served to guide and keep in alignment. Between the lower guide casting and the foot-pedal bracket was disposed a collar firmly fastened to the broach holder, and attached to this collar was a yoked lever. This lever was so fulcrumed that the weight of the broach was just slightly more than counterbalanced by a cast-iron weight which insured the broach end of the holder being piloted in the quill when the broaching was being done. A hand lever with lift rods was attached to the yoked lever to control the loading.

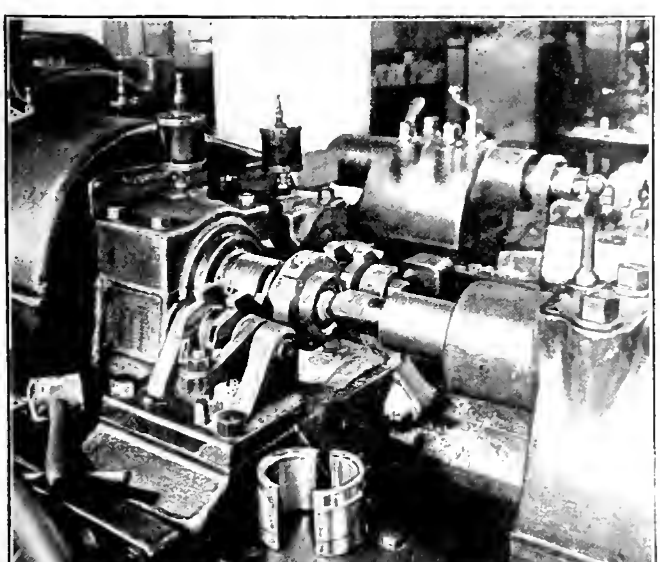

Fig. 10 Method of Cutting Grooves for Forked-End Rod—Operation 17

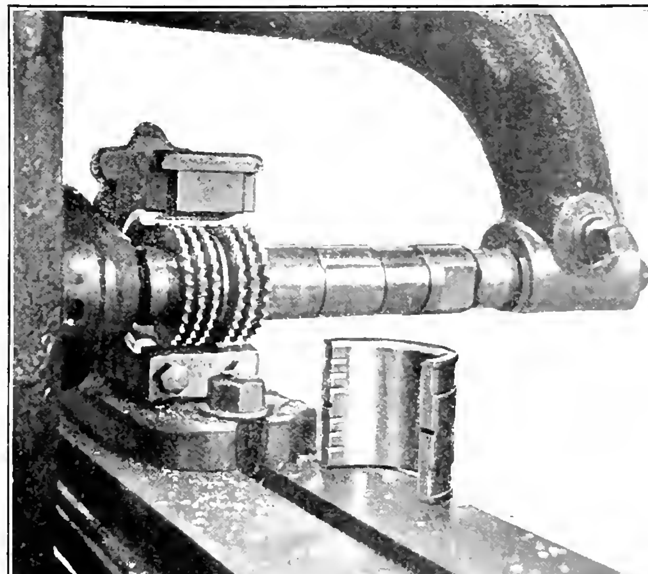

Fig. 11 Method of Cutting Oil Grooves—Operation 20

The broach had eight cutting edges varying in size from 2.422 in. diam. to 2.4273 in. diam. In addition to the cutting edges, the upper end of the broach had three burnishing surfaces, the diameters of which were 2.4274 in. The broach was 5 in. long and had a hole ground to 1.625 in. diam. to fit the end of the broach holder.

In operation the keyseater functions normally, with the exception that the down (or what would be the return) stroke of the ram is utilized for pushing the broach through the work. The hand lever controlling the broach holder is pulled down until the latch on the foot lever engages the top of the collar on the broach holder. This operation holds the pilot end of the holder and the broach-holder quill apart, allowing the broaching ring containing the work to be mounted in place. The broach holder was then allowed to ascend until the end of the holder protruded enough to allow slipping on the broach, and then further until its end was piloted in the hole of the quill. The machine was then tripped and the broaching was done on the downward stroke of the slide carrying the quill, the broach being forced through the work by the pressure exerted on descending quill. This downward stroke was carried far enough to allow the foot-lever latch to engage the collar on the broach holder automatically. The machine was reversed, disengaging the quill and the broach holder. The broaching ring containing the work was then lifted out and the broach was removed from the holder, leaving the machine ready for the next operation.

Operation 9—Press Out of Broaching Ring. This operation has been previously described under Operation 7, and is shown in Fig. 6.

Operation 10—Grind Outside Diameter to 3.075 In. The bushing was ground between centers on a 6 x 18-in. plain grinder. A split hardened steel ring ground on its outside to a diameter of 2.4275 in. was inserted in the bushing and a hardened arbor ground with a slight taper was in turn inserted into the split ring, the hole of the latter being ground tapering to conform to the arbor. A light pressure applied to the end of the arbor expanded the ring sufficiently to firmly hold the bushing for grinding.

Operation 11—Cut in Halves with 3/64-in. Saw (2 on). This operation was done on a plain milling machine with an indexing type of fixture. The work-holding arbor of the fixture was made long enough to accommodate two bushings. The bushings were clamped on the arbor with a "C" washer and stud bolt. A common 3/64-in.-wide milling cutter was used.

Operation 12—Close In. After being cut in half, the bearings were bent to decrease their diameter so as to allow their fitting easily into the swaging fixture used in Operation 13. The bending fixture, Fig. 8, was made with a semicircular arbor bolted to a base plate. A housing with three cam-lever slides was fastened to the base plates. Openings in both sides of the housing allowed for the insertion of the bearing over the arbor. The top cam lever clamped the work in position and the side cam levers closed in the bearing the necessary amount.

Operation 13—Swage. This operation, which was performed on a press, was the keystone operation in the successful production of accurate bearings, as the set given them insured their holding the shape of the master forms.

The fixture, Fig. 9, comprised a hardened and ground steel base plate fastened to a hardened steel form. Two eyebolts were held by pins in each side of the form. These parts assembled formed the female section and were fastened to the bolster plate. The male section was made up of a half-round arbor of hardened steel on the clamping plate, the joining surfaces of which were also ground. Two slots in each end of the clamping plate allow the eyebolts to hold the two sections together. A tongue-and-groove construction on the joint surfaces of the sections kept them in alignment. A filler piece made of hardened steel and ground to the finished bearing dimensions was used to take the flow from the ram of the press. A hardened-steel cylindrical punch with a flat-ground bottom surface was fitted into the ram of the machine.

In operation, a half-bearing with a filler piece on top of it was clamped between the male and female section of the fixture; the press was then tripped and the cylindrical punch on descending struck the filler piece, which projected slightly above the upper surface of the fixture. This upset the metal to the finished bearing dimensions with an allowance on the parting-line surfaces of about 0.003 in. for finish-milling.

Operation 14—Finish-Mill the Parting Line. A plain milling machine on this operation was very satisfactory considering the close limits of plus or minus 0.00025 in. A fixture with a half-round seat or nest bored to fit the outside diameter of the half-bearing was bolted to the plate of the machine. The parting-line surfaces of the half-bearing were leveled by the hinge gage attached to the fixture. The work was clamped with a half-round hardened and ground steel clamp, the curved surface of which was made to fit the inside diameter of the half-bearing. Two plain milling cutters were mounted on the arbor and were so spaced that they straddled the clamping bolt and nut.

Operation 15—Face Ends to Length. A 14-in. x 4-ft. lathe without a tailstock was used for this operation. A hinged clamping ring was used to clamp the work tight on the steel arbor, which was mounted in the spindle of the lathe. Two halves, or one complete bearing, were machined at one setting. A special tool block with two cutters straddling the clamping ring faced the bearing to the proper length.

Operation 16—Fillet Both Ends. The fillet cuts in both ends of the bearing, to clear the radius of the crankshaft pin, was done on 21-in. drill presses. The fixture comprised a circular-shaped base bored in the center to receive a flanged hardened-steel pilot bushing. The outside diameter of this pilot bushing above the flange was made to fit the inside diameter of the bearings and the hole of the pilot bushing was a fit to the pilot of the filleting cutting holder. The half-bearings were clamped in pairs about the piloting bushing by means of two hinged clamps rotating on a pin located in the rear of the fixture. A single formed filleting center was fastened in a slotted holder. The holder was held in the spindle of the drill press with a tapered shank.

Operation 17—Cut Two Grooves for Forked-End Rod. A 14-in. x 5-ft. lathe, Fig. 10, with a special cross-slide arranged with front and back tool blocks, was used for this operation. A stub arbor mounted in the spindle of the machine was made with a flange to serve as a stop for locating the work while clamping with a hinged ring, similar to the one used for Operation 15. The half bearings were clamped on the arbor at one setting. The arbor was provided with a center so that the lathe tailstock could be utilized to stiffen the support of the work under the pressure of the cut. The grooving cutters were of the circular forming type, with six cutting edges. The adjustment of the cutting edges was controlled by the movement of a toothed lever. The teeth of this lever meshed with the teeth in the boss about the center of the grooving cutter. The cutter in the rear tool block was used for roughing, and the front cutter for finishing. Suitable stops were arranged on the cross-slide to control the depth of the cut.

Operation 18—Drill and Ream Dowel Holes in Lower Half-Bearings Only. A two-spindle 14-in. drill was used on this operation. The drill jig comprised a base with side supports, to which was fastened the drilling plate. On the under side of this plate was fastened a locating block formed to fit the contour of the work. A slide disposed between the side supports and actuated by a cam lever served to clamp the work in position for drilling and reaming. Slip bushings were used in the drilling plate, one for the drill and one for the reamer to insure accuracy.

Operation 19—Cut Two 1/8-in. Semicircular Oil Grooves on the Parting Line. This operation was done on a hand miller. The cast-iron fixture supported the work in a semicircular nest and was clamped in place with a strap and thumbscrew.

Operation 20—Cut 12 Oil Pockets in Both Halves. This operation was also done on a hand miller. The fixture, Fig. 11, was made to so clamp the work that the parting surfaces were in a vertical position. The oil pockets were cut on a radius; the cut being 1/32 in. deep at the parting line and running out to the inner surface of the bearing 1/4 in. below the parting line. An arbor with six 1/32-in. wide plain cutters properly spaced was mounted in the spindle of the machine and supported by the over arm.

Operation 21—Burr. A No 1 keyseater was used for removing

(Concluded on page 556)

Economy of Arizona Power Plants Using Oil Fuel

By C. R. Weymouth,[1] San Francisco, Cal.

This paper treats of the performances of three steam-electric power plants situated in Arizona where load factor and high fuel cost demand economical operation. Tables and curves of operating characteristics are accordingly given and some of the difficulties encountered in practice are enumerated.

In certain Arizona steam power plants the combination of favorable load factor and high fuel cost has not only nessitated but has also made possible the attainment of high fuel economy, and even in plants where cooling ponds are used for condensing purposes. This paper refers to the performance of three such power plants, namely, those of the Inspiration Consolidated Copper Company, Inspiration, Ariz.; the New Cornelia Copper Company, Ajo, Ariz.; and the Arizona Power Company, Clarkdale, Ariz. These plants embody many similar features. They differ, however, in methods of condensing as cooling ponds are used at the Inspiration and New Cornelia plants, and water from the Verde River at the Arizona Power Company's plant.

The Inspiration plant was designed in the winter of 1913-14. The International Smelting and Refining Company's smelter adjoins the Inspiration power plant site, and the steam generated in wasteheat boilers in the smelters is utilized for the operation of the reciprocating blowing engines, which are designed for about 175 lb. steam pressure. These blowing engines are located in the same power-plant building as the steam turbines, and since the waste-heat boilers are connected to the same steam header as the oil-fired boilers, their steam pressure and the economy of the turbine plant have been limited by the common steam pressure of from 175 to 185 lb. The New Cornelia Copper Company's plant was designed in the winter of 1915-16, and being independent of blowing engines, the boilers were selected for 250 lb. pressure. While a higher steam pressure would have been possible, the remote location of the plant and experience at the date of design led to the lower boiler pressure being selected. The Arizona Power Company's plant was designed in the winter of 1916-17, and has boilers for 250 lb. pressure.

The Inspiration plant is 25-cycle, 3-phase, 6500 volts. The New Cornelia plant and the Arizona Power Company's plant are both 60-cycle 3-phase, 2300 volts. The maximum load at the Inspiration plant was estimated to be 12,000 kw.; three 6000-kw. Curtis turbines were therefore selected, thus giving one spare turbine. For the New Cornelia Copper Company's plant the load was estimated to be 7500 kw., and this led to the selection of two 7500-kw. turbines, one unit being a spare. The Arizona Power Company's plant was designed as an auxiliary to a hydroelectric system, and intended to carry a peak load of 5000 kw. Owing to the quick shipment required, however, a turbine previously ordered for another company, and rated at 6000 kw., was installed, whereas the remaining equipment was selected for a 5000-kw. load.

All three plants have Stirling steel-encased boilers, with Peabody-Hammel oil furnaces, Green fuel economizers, Moore automatic fuel-oil regulating systems, Wheeler surface condensers, Wheeler dry vacuum pumps, centrifugal hotwell pumps, direct-connected exciters, steamer-driven boiler-feed pumps, etc. Superheaters are installed in all plants, specified to give 100 deg. superheat for the Inspiration plant, and 150 deg. superheat for both the New Cornelia and the Arizona Power Company's plants, all measured at the boiler, and at normal rated capacity of boilers. All the plants also have centrifugal circulating pumps, the Inspiration pumps being turbine-driven, and the others motor-driven.

[1] Chief Engineer, Chas. C. Moore & Co., Engineers. Mem.Am.Soc.M.E.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, of The American Society of Mechanical Engineers. All papers are subject to revision.

The nozzles for the cooling pond for the Inspiration Copper Company's plant were furnished by one of the spray pond companies, who also proportioned and designed the pond arrangement. The actual vacuum shown by the operation of this plant, however, has been a disappointment, as a pond of insufficient area was installed. Since the design of the Inspiration plant this detail has been corrected by the addition of cooling towers. The condensate is returned to the oil-fired boilers, and make-up water for the pond is purified by a Booth water softener. A Cochrane hot-process purifier purifies the make-up for the oil-fired boilers if needed, but it is primarily for purifying boiler feed for the waste-heat boilers installed at the smelter. The blowing engines operate at slightly lower vacuum than the turbines, and advantage is taken of this fact to heat slightly the turbine condensate by passing it through the Volz heaters in the surface condensers of the blowing engines.

Cole-Bergman water weighers and Lea recorders are installed for feedwater measurements, for computing the steam supplied from the waste-heat boilers and the steam required by blowing engines, as well as the steam consumption of the turbines. Steam-flow meters are also used for checking purposes. By this means a separate record is kept of the economy of the turbine plant on the basis of operation independent of the blowing engines.

The feedwater for the New Cornelia plant contains from 30 to 50 grains of impurities per U. S. gallon. The water is low in calcium sulphate and carbonate, high in sodium sulphate, and very high in sodium chloride. It is not practicable to purify this water by chemical treatment. The condensate from the condensers is returned to the boilers, and raw make-up water is used for the pond and boiler-feed make-up purposes. Frequent blowing down is required for the cooling pond, as well as for the boilers. Scale is also formed both in the condensers and the boilers, and this requires frequent cleaning, as condenser scale tends to impair the vacuum.

The Arizona Power Company uses Verde River water for condensing purposes, this being taken through a flume at such a point that the pumping head is reduced by gravity flow. The condensate is returned to the boilers, and the raw make-up water is purified in a Cochrane hot-process purifier.

Economy of Inspiration Consolidated Copper Company Plant

Upon the completion of the Inspiration plant it was placed in regular service. The performance of the individual pieces of apparatus was investigated in order to make certain that everything was working to the best advantage, particular attention being paid to the efficiency of boilers, the adjustment of burners, furnaces, and the automatic firing system. A number of uniform load tests were made of boilers for checking purposes, and the results obtained are given in Table 1 and the curves of Figs. 1 and 2. These tests show a fairly high efficiency at rating, and, rather contrary to the usual results obtained with non-easing boilers, a higher efficiency at fractional loads than at rating. The higher efficiency is due to the tightness and the insulating efficiency of the steel casing. As a result of these tests, instructions were given the operators to divide the load equally among all boilers and this, of course, was done automatically by the firing system. The operators, however, were instructed to keep as many boilers on the line at light loads as could be properly fired, maintaining a fire in each of the three burners per boiler; below this load boilers were cut off the line, and only refired when the load again increased.

The curves of Figs. 1 and 2 show the relation between the steam pressure of the atomizing steam and the oil pressure, both

measured in the supply pipes at the individual burner, between the throttle valve and burner. From data obtained from these curves, the steam-to-burner regulator was set to give the proper pressure of atomizing steam, based on the momentary oil pressure.

A complete description of the automatic oil-firing system in use in these plants will be found in a paper by the writer entitled Unnecessary Losses in Burning Oil Fuel, and an Automatic System for Their Elimination, page 797, Vol. 30, of

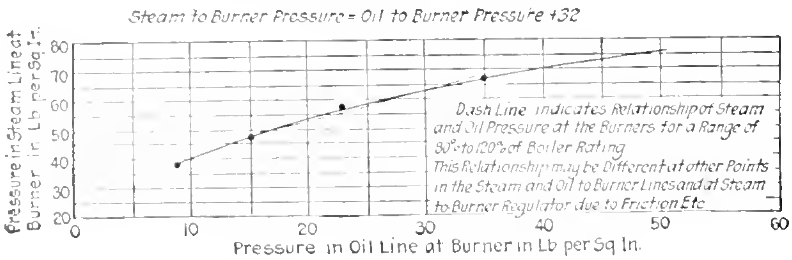

Fig. 1 Steam and Oil Pressures at Burner Lines

Transactions, and the system used in these plants differs from that described in the paper merely in the use of a diaphragm pump governor to maintain a constant predetermined maximum pressure at the oil pumps; the oil-to-burner regulator then operates a throttle valve to give the desired pressure at the oil burners.

Under variable load the damper controller has been able to maintain CO_2 readings varying from 12 per cent to 14.5 per cent CO_2, for which the corresponding excess air for normal conditions is 28 per cent and 6 per cent, respectively.

After instructing the operators, and while the plant was still under the control of the engineers, an average economy was obtained for the month of September, 1915, as given in the following table:

Average number of turbine units in operation	1
Average daily load, 24-hour basis, kw	5980
Average steam pressure at boilers, lb. per sq. in.	178
Average vacuum in condensers, in. of mercury, absolute	2.66
Average rating on boilers, per cent	95
Gross boiler efficiency, per cent	80.9
Average economy, kw-hr. per bbl. of oil as fired	281
Average economy B.t.u. per kw-hr.	2,5900

In the subsequent operation of this plant by the owners the economy has been maintained practically equal to that shown under the direction of the engineers, but during the winter, due to colder circulating water, the economy is even better than indicated above. On the other hand, during the summer months, with the warmer circulating water and falling off in vacuum, the economy naturally drops to a lower figure than that given for the month of September.

This plant operates in conjunction with the hydroelectric plant at the Roosevelt Dam, and at periods of the year preference is given to hydroelectric power. As a result, there is a fractional load, or partial shutdown of the steam plant, and for certain months this in turn has naturally resulted in a reduced economy.

The operating results for the plant, furnished by Mr. W. W. Jourdin, Mem.Am.Soc.M.E., Chief Engineer of the Inspiration power plant, are given by the curves of Fig. 3. It will be noted that the best monthly economy for winter conditions has been 294.5 kw-hr. per bbl. of oil, or 20,910 B.t.u. per kw-hr.; and the poorest economy for summer conditions for the normal load has been 257.5 kw-hr. per bbl. of oil, or 23,700 B.t.u. per kw-hr., although for the month of September 1917, due to the very light load, the economy was only 237 kw-hr. per bbl. or 25,970 B.t.u. per kw-hr. As previously stated, this plant, in comparison with non-cooling-pond plants, is subject to an accumulation of scale in the condensers, and as a result there is a slight loss in vacuum. Since purified feedwater is used, the plant is not subject to troubles from scale formation in the oil-fired boilers, nor does any loss of fuel result from shutting down boilers for cleaning or boiler blow-off.

The curves of Fig. 3 give the operating records for combined boiler and economizer efficiency, atomizing steam deducted; this being the form in which the power-plant records are kept. A comparison of this result with the boiler efficiency tests would seem inconsistent without the explanation that the economizers at this plant heat the feedwater through a temperature range of from 40 deg. to 45 deg., whereas it will be noted that results for the Arizona Power Company's economizers, given in Table 2, indicate a temperature rise in the economizer of 91 deg. fahr. In proportioning the Inspiration economizers with reference to the investment and fuel saving, it was assumed that the average period of operation would be less than half the year, owing to the use of hydroelectric power; it was also assumed that the fixed charges would be very high. This combination of circumstances, together with high freight rates and construction costs in Arizona, resulted in the selection of an economizer of comparatively small surface, giving a favorable return on the investment but a result considerably less favorable than that attained in the average economizer with oil fuel, when measured only by temperature rise.

Economy of the New Cornelia Copper Company's Plant

Following the installation of the New Cornelia plant in November 1917, an attempt was made by the designing engineers to check the economy of the station, but owing to the war and a scarcity of labor this work had to be abandoned before completion. While it has never been possible to show the best performance of which the plant is capable, the operating crew have, for the most part, been very efficient in handling it, except during an illness of the chief engineer, when the economy of the plant fell off to a disappointing figure. This occurred during the summer and fall of 1918, and the figures for economy for that period are thus hardly fair to the plant. It should also be borne in mind, in connection with performance data, that the feedwater condition at this plant is such that the frequent shutdowns for boiler cleaning and the large amount of hot water blown off from the boilers affect appreciably its economy.

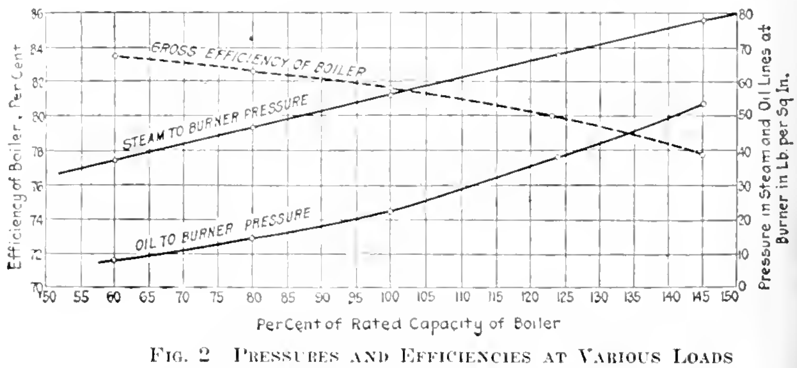

Fig. 2 Pressures and Efficiencies at Various Loads

This plant, due to its location in the southwestern portion of Arizona, is subject to more intense summer heat than probably any other power plant in the western territory, and this in turn gives rise to considerably less favorable cooling-pond and condenser performance, with respect to vacuum, for the summer months than for the winter months. The vacuum performance is also influenced by the accumulation of scale within the condensers between the periods of cleaning condensers, due to concentration of salts in the cooling pond.

The best economy for this station known to the writer is for the month of January 1918, the average performance for four successive days being about 324 kw-hr. per bbl. of oil, as shown in the following table:

Date 1918	Average load, kw.	Economy, kw-hr. per bbl. of oil	B.t.u. per kw-hr.
January 26..........	7921	321.7	18,975
January 27..........	7830	324.1	18,833
January 28..........	7725	324.2	18,829
January 29..........	7800	326.2	18,711

The poorest economy for this station, during the summer of 1917, was for the month of July, namely, 293.5 kw-hr. per bbl. The average vacuum was 1.66 in. absolute and the average load 5550 kw. The poorest economy during the summer of 1918 was also for the month of July, or 287.5 kw-hr. per bbl. The average vacuum was 2.14 in. absolute, the average load 5850 kw., and consequently the economy for the summer of 1918 was abnormally low.

The monthly report for December 1918 gives the following: Average load, 7800 kw.; average economy, 312 kw. per bbl. and 19,913 B.t.u. per kw-hr. The monthly report for January 1919 gives: average load, 7790 kw.; average economy, 317.9 kw. per bbl., and 19,535 B.t.u. per kw-hr. The improvement for the month of January over December is due to a straightening out of the aforementioned difficulties experienced in the summer of 1918, and it is the writer's belief that the station will soon be operating at its best previous economy for the corresponding season.

It will be noted that the economy of the New Cornelia plant is materially better than that of the Inspiration. This is due somewhat to the larger turbine units installed, but in the main to the higher steam pressure and to the improved design of cooling pond, which results in better vacuum. In comparing the economy of these cooling-pond stations with that obtained in tidewater plants, allowance should be made for the size of turbine units, the obtainable vacua under operating conditions, the increased head on circulating pump due to the greater quantity of water which must be handled through the condensers, and the increased pumping head due to the cooling-pond nozzles and longer lengths of circulating-water line.

Economy of the Arizona Power Company's Plant

This plant was completed in September 1917, and due to the war conditions in the mining region it was difficult to assemble a skilled operating crew. The plant was furnished under a contract covering a complete plant-economy guarantee at 5000-kw. load, and the final test, covering 48 hours' operation in regular commercial service, under variable load, was concerned mostly with the economy at this load, although a run was made at 6000-kw. load, which is the rated capacity of the turbine. The results for the final test are given in Table 2. At all times during this test the plant was subject to a variable load, due to the regulation of the hydroelectric system. The oil was carefully weighed and the electrical output was measured by calibrated meters. The electrical output given is the net useful output for the station at the 2300-volt bus, deduction having been made for the power consumption of electric auxiliaries, including lighting for the operators' cottages, circulating water pump, deep-well pump and air washer. The average electrical auxiliary load was 46 kw., which is somewhat smaller than would have been the case had the entire head on the circulating water been overcome by pumping; against this condition is the fact that during the test the quantity of circulating water was somewhat less than specified, so that, roughly speaking, the one condition nearly offsets the other.

It is not possible to give daily operating results for this plant, at the load for which it was designed, for since its installation it has been maintained only for reserve purposes, carrying occasional peaks but the majority of the time a very light load, and for a number of hours during an average day with the turbine at standstill. Of course favorable economy is not possible under such conditions, as the fuel losses due to keeping hot boilers, piping, etc., the dead-load losses for the operation of auxiliaries, and the zero-load steam consumption of turbine result in a zero-load fuel consumption of the plant which is an appreciable percentage of the full-load fuel consumption. With the foregoing explanation, the results for February 1918 are as follows:

Total kw-hr.	1,235,580
Total bbl. of fuel oil used	4783.9
Total hours of operation	444
Average kw. for operating period	2800
Kw-hr. per bbl. of oil (delivered to lines, net)	258.5
Operating period load factor	0.467
Average kw. for monthly period	1838
Monthly period load factor	0.306

It is of interest to note that the turbine at the Arizona Power Company's plant is practically a duplicate of those at the Inspiration Copper Company's plant, having the same number of stages; the difference in the operating economy of the turbines being largely due to steam pressure. Here again is a marked

Per cent excess air over chemical requirements at front of damper		4.19		4.19	6.14

[1] Apparent discrepancies in the draft readings of power-plant instrument and thermometers are due to the different location of the nozzles and to slight leaks in flue-gas piping.

[2] On account of the waste-heat boilers and intermittent firing of the other boilers the load was very jerky. On this account the damper was fixed to a low point on the draft and the ashpit door was regulated during the test.

TABLE 2 RESULTS OF TEST OF THE ARIZONA POWER COMPANY'S STEAM PLANT AT TAPCO, ARIZ.

Duration of test, hours	6
Boiler pressure, lb. per sq. in., gage	250
Steam pressure at turbine throttle, lb. per sq. in., gage	238.5
Avg. temp. of superheated steam at boilers, deg. fahr.	546

B.t.u. per kw-hr., gross	18,478
B.t.u. per kw-hr. net	18,628

increase in plant economy due to an increase in steam pressure, and also by reason of the colder river water at the Arizona Power Company's plant as compared with the cooling-pond water at the Inspiration plant and the consequent improvement in vacuum. All economy figures are based on oil as fired, without deduction or correction for moisture, sulphur, or silt.

The engineers have endeavored to instill in the minds of the operators of these plants and to show by example that high economies need not merely be looked for during the test period, but can be maintained during the operating period. The Inspiration plant is large enough to permit the employment of a boiler-room engineer, but, due to their smaller size, such an engineer is not maintained at the other two plants. This plant was designed on the assumption that the average load would be maintained for a period of six months only during the year, and that oil delivered would cost about $1.45 per bbl. The New Cornelia plant was designed on the assumption that oil would cost $1.25 per bbl., but since the date of design of these plants the cost of oil has materially increased.

PERSONNEL

The selection of the principal equipment for the Inspiration plant and its general layout were made jointly by John Langton, Consulting Engineer for the Inspiration Consolidated Copper Company, and Chas. C. Moore and Co. Engineers, which firm was also responsible for the detailed designs, installation and tuning up of the plant.

For the New Cornelia plant the entire work was in the hands of Chas. C. Moore and Co. with the approval of A. G. McGregor, Consulting Engineer for the New Cornelia Co.

The Arizona Power Company's plant was designed and built by Chas. C. Moore and Co. Engineers, with the approval of R. S. Mason, Chief Engineer for the Arizona Power Co.

A considerable portion of the testing work on the Inspiration plant was handled by A. G. Budge, under the writer's direction, and for the New Cornelia and Arizona Power Company plants by T. B. Paulson, also under the writer's direction.

Air Fans for Driving Generators on Airplanes

By CAPT. G. FRANCIS GRAY[1], U. S. A.; LT. JOHN W. REED,[1] U. S. A.; and P. N. ELDERKIN [1]

In this paper the authors first briefly describe the method employed by the Radio Development Section of the War Department in testing air fans used for driving the electric generators usually installed on airplanes for radio communication. They next discuss at some length the various types of air fans used during the war and present numerous photographs and curves clearly illustrating the construction of the fans and their operating characteristics.

The difficulty of the problem lay in designing a fan which would turn at constant speed in the air streams of widely varying speed set up by the airplane in flight. The various types of fans tested were: Fixed-blade fans of special blade shape; fixed-blade fans with wind brakes centrifugally regulated; fixed-blade fans using a friction clutch or a friction brake centrifugally regulated, and pivoted-blade fans in which the pitch is centrifugally regulated.

DURING the war extensive use was made of radio telegraph and telephone apparatus on military airplanes, and the problem of power supply for such equipment received a great deal of attention. The possible sources of energy may be listed as follows:

a Storage batteries or dry batteries
b Generators driven from the airplane engine, with or without floating storage batteries, and supplying the radio sets directly or through dynamotors
c Generators driven by separate gasoline engines
d Generators driven by air fans, or "windmills" placed in the air stream outside the airplane fuselage.

From an economical point of view, method *b* is preferable. It was seriously considered, but since it involved coöperation between organizations normally operating independently, its adoption was delayed. Meanwhile the practice in our Army followed that of our Allies, principally the French, in the use of method *d*, mounting the generator outside the airplane fuselage and driving it with an air fan.

The work done on the development of air fans for this service was carried out by the Radio Development Section of the Signal Corps, and since it was done under the press of military necessity it was directed entirely by utilitarian considerations, was often fragmentary, and neglected investigations, the need of which was realized, but for which time and personnel were not available. This record is presented with the work still in unfinished form in the hope that results obtained may be useful to those who may have occasion to carry out further investigations on the problem.

Conditions for Which the Air Fans Were Designed

Two sizes of generators were to be driven by the air fans it was desired to develop. The essential data on these are as follows:

	Generator for Radio Telegraph Sets	Generator for Radio Telephone Sets
Generator diameter, in.	6¼	4 13/16
Generator output, watts	200	80
Required power from fan, watts	330	250
Normal speed, r.p.m.	4500	4000

[1] Engineering and Research Division, Radio Development Section, War Department, Washington, D. C.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

Methods of Test

Practically all of the tests recorded in this paper were made with the wind tunnel of the Bureau of Standards, and the management and personnel of the Bureau aided materially in expediting them. A special testing generator was mounted in the wind tunnel and the fan to be tested was attached to it. This generator was provided with a magnetic tachometer, a separately excited field, and convenient means for applying load to the armature circuit. The external shape and size of the machine were made identical with those of the radio generators, with which the air fans were to operate in service, and with this generator and the regular wind-tunnel equipment for measuring wind velocity, tests could be made rapidly and accurately.

All of the air fans considered in this development have normal speeds of 4000 r.p.m., or above, and the centrifugal forces are very considerable. It was therefore found necessary to provide an overspeed test to precede the wind tunnel test. For this purpose a 30-hp. motor operating through a 43-to-3 De Laval speed-increasing gear to a suitable shaft extension for the fan was set up. This device was capable of driving the air fans at speeds up to 14,000 r.p.m. and to prevent damage to gears or bearings in case of failure of the fan, a "weakest point" was provided by a replaceable notched-shaft extension. Failure at this point merely resulted in the breaking of the replaceable shaft extension and of course the destruction of the fan, without injury to bearings or gears. Heavy guards prevented the flying fragments from causing any damage. This equipment was designed by Capt. F. E. Pernot, Officer in Charge of the Signal Corps Laboratories at the Bureau of Standards.

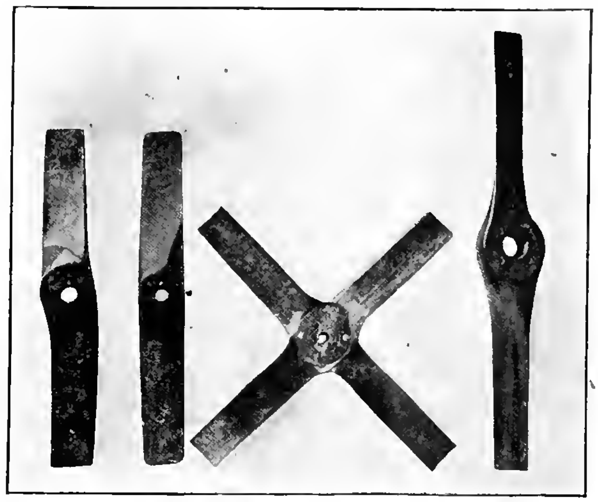

Fig. 1 Pre-War Air Fans

There is one serious objection, however, to this method of overspeed testing in that it absorbs a large amount of power and puts abnormal thrust strains on the fans. A baffle to prevent air flow materially reduced this effect, and later experience indicated that it would have been preferable to make the overspeed test in a very simple auxiliary wind tunnel with an aperture just large enough to drive the unloaded fans at the speed desired. Nevertheless the apparatus just described was used in all tests discussed in this paper.

In cases where the strength of a fan was problematical, it was first given an overspeed test only slightly in excess of the running speed expected in the wind tunnel. After the wind-tunnel test it was again tested to the required overspeed or to destruction. The best fans were required to withstand up to practically double normal speed.

Simple Non-Regulating Air Fans

As in all power-plant problems, the ideal in this development was a constant-speed drive for the radio generator. When the development began, the only air fans available were non-regulating wooden fans such as those illustrated in Fig. 1. These fans have the characteristic that rotational speed is practically proportional to air speed, and when combined with the normal variations in the speed of the airplanes this fact leads to very severe requirements for the generator. As an example, a generator which would give satisfactory performance at 3750 r.p.m. was required to withstand an overspeed test of 14,000 r.p.m. for mechanical performance and, with the addition of a very special regulating device, to hold its voltage within 15 per cent at speeds from 4000 to 12,000 r.p.m.

Although the need for better air fans was obvious, the non-regulating types had to be used until others could be developed, and a considerable amount of work was done in adapting them to the particular requirements to be met. Fig. 2 shows the construction of one of the final forms used with generators for radio-telephone sets, and Fig. 3 its performance in the wind tunnel. Figs. 4 and 5 give similar information on a larger-size fixed-blade fan used for radio-telegraph sets. Fig. 5 also gives an idea of the variation in individual fans supposed to be identical. Considerable trouble was experienced with these fans due to the fact that the method for calculating air fans was assumed to be the same as that used for propellers.

Obviously it is desirable to establish the correct method of calculating these fans, but the pressure of more important work prevented its being undertaken by the Radio Development Section. The subject, however, was given much attention by Mr. E. N. Fales, of the Airplane Engineering Department, Bureau of Aircraft Production of the Army, who assisted the Section very materially during the early stages of the development described in this paper, and it is hoped he will publish his conclusions.

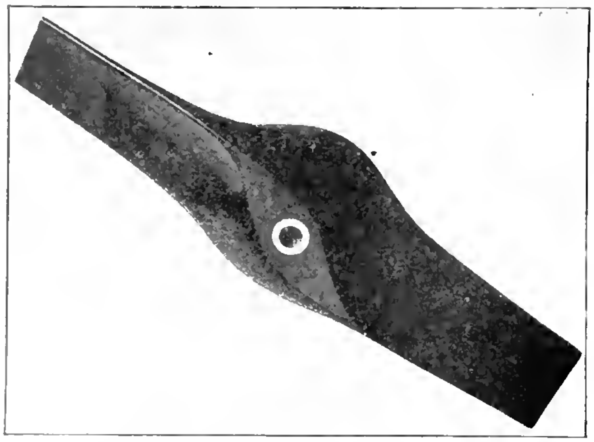

Fig. 2 Type FA-3, Non-Regulating Air Fan, for Radio-Telephone Generators

Regulating Air Fans

No one can work with simple air fans without being impressed with the desirability and apparent simplicity of modifying them so that instead of the straight-line relation between air speed and speed of rotation there will be more or less tendency toward constant rotational speed with varying air speed. Among the disadvantages which may be corrected by making the air fans self-regulating are the following:

a Undue head resistance
b Excessive centrifugal stress in armature windings
c Vibration
d Commutator and bearing troubles
e Troubles with voltage regulators
f Troubles in radio sets due to varying voltage.

During the progress of this development a great many schemes for the construction of self-regulating fans were proposed. As all previous experiences led to the conclusion that the performance of a fan could not be predicted with any degree of accuracy, every reasonable suggestion was carefully considered and if possible tried out. Fundamentally all the fans tested may be classified under five principles of operations as follows:

a Fixed-blade fans of special blade shape
b Fixed-blade fans with wind brakes centrifugally regulated
c Fixed-blade fans using a friction clutch centrifugally regulated
d Fixed-blade fans using a friction brake centrifugally regulated
e Pivoted-blade fans in which the pitch is centrifugally regulated.

Fixed-Blade Fans of Special Shapes. Certain air fans submitted to the Signal Corps were supposed to give speed regulation on the principle that the angle of attack and efficiency can be made to alter with the wind velocity in such a way that the ratio of wind velocity to r.p.m. need not be constant. Tests were made first on a series of blade sections and later on a fan, shown

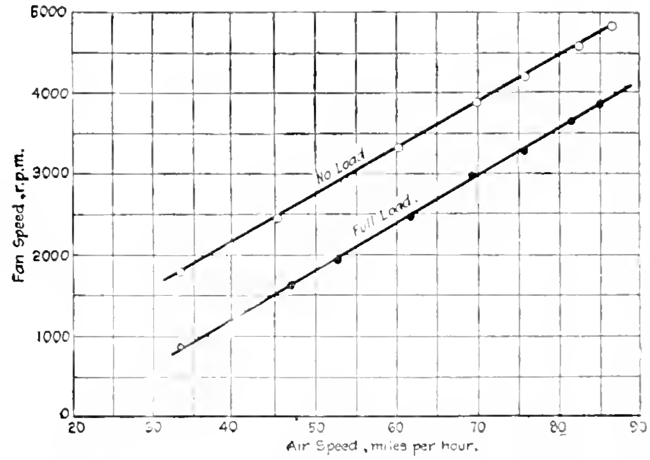

Fig. 3 Performance Curves of Type FA-3 Air Fan
(Diam., 15 in.; pitch, 2.1 ft.)

at the right in Fig. 1, which was said to possess the regulating features in a marked degree. The conclusion from these tests was that at no load the performance of properly designed fans tends to confirm the hopes of the designers though the magnitude of the regulating effect is small; but under load, particularly varying load, it was impossible to distinguish any improvement over the ordinary fixed-blade types of fans. Consequently this method was discarded as of no practical value.

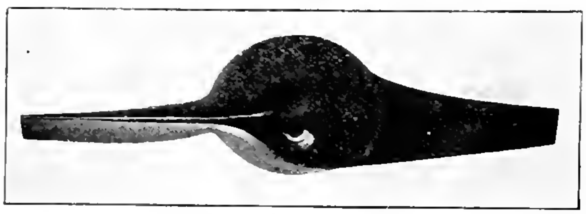

Fig. 4 Type FA-6, Non-Regulating Air Fan, for Radio-Telegraph Generators

Fixed-Blade Fans with Wind Brakes. Fans of this type are provided with wings, pins or other projections which are normally enclosed in a recess in the blade, but which are caused by centrifugal force to emerge and so retard the rotation of the fan. They have the disadvantage of low efficiency and consequent high head resistance, but were considered worth trying. Fig. 6 shows various development models. Round rods, rods with cloth and metal wings, flat strips, etc., were tried for the moving brake element. Many showed practically no regulation of course, but others were reasonably promising. Among such was the type in which the brake arms were pivoted and moved out into the

air by the action of centrifugal weights. Another interesting fan had the break arms actuated not by centrifugal force but by the air pressure on a plate mounted in advance of the nose of the fan, and gave a curve in which, for a certain range, the r.p.m. actually decreased with increase in air velocity.

The net conclusion from this research was that the wind-brake principle would give fairly good characteristics over a limited range of air speed, and with further refinement it might have been worth putting into production. However, that stage was never reached due to the work on the pivoted-blade type of fan described below.

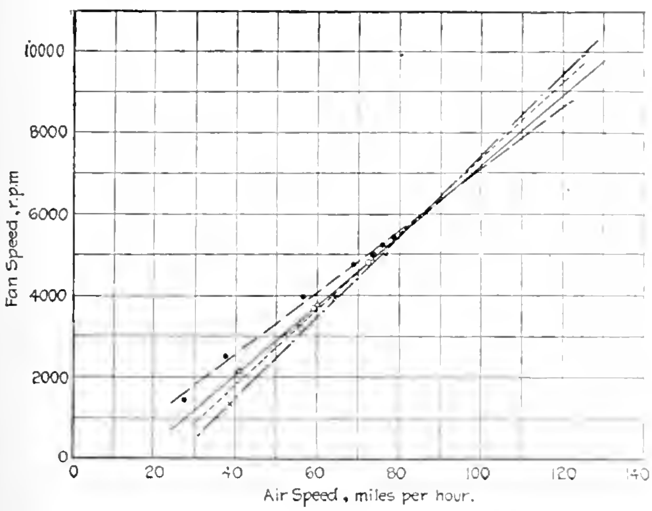

FIG. 5 PERFORMANCE CURVES OF TYPE FA-6 AIR FAN
(Diam., 20 in.; pitch, 1.75 ft.)

Friction-Clutch and Friction-Brake Fans. As in the types of regulating air fans discussed above, the friction-clutch and friction-brake principles of operation are inherently objectionable on account of their low efficiency and consequent high head resistance. They offered a possible solution, however, and were tried out experimentally. In the friction-clutch type of fan the fan hub is capable of free rotation about the shaft of the generator, which it drives through a friction clutch. The clutch is released by the action of centrifugal weights when the speed passes the predetermined maximum, permitting the fan to run at higher speed than the driven shaft of the generator. The curve of this fan

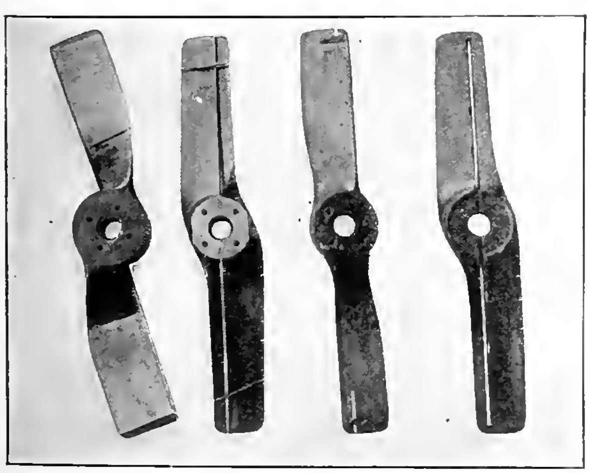

FIG. 6 FIXED-BLADE FANS WITH WIND BRAKES

was satisfactory for the first model, but the heating due to slipping of the clutch at high velocities was too great to permit the use of the fan in practice and the development was abandoned.

In the friction-brake type of fan the fan is keyed to the generator shaft and is prevented from exceeding normal speed by a brakeshoe operated by a centrifugal weight and bearing on a plate attached to the generator frame. This also was tried, and gave results essentially similar to those obtained with the clutch type. With the very considerable variation in air speed met with on airplanes, the friction devices generated so much heat that their use was impossible.

Variable-Pitch Air Fans. The ideal principle for the design of a regulating air fan is that of varying the pitch of the blades to correspond to the variation in air speed; this principle is by no means new, having been considered in a variety of forms for propellers for a number of years. The great difficulty in actual construction has been that the mechanical strength necessary to withstand the very high centrifugal forces and the delicacy of operation necessary for close regulation are very hard to combine.

This objection does not apply so forcibly to fans using very thin blades which are expected to warp under centrifugal action to change the pitch and a few samples which it was hoped would operate on this principle were tested. They were unsuccessful principally on account of mechanical construction and improved samples were never made up. The method is in any case of doubtful utility since it can probably take care of only limited variations in speed, whereas the pivoted blade fans are capable of regulating over the widest variations in air speed likely to be met with in airplane practice.

Pivoted-Blade Air Fans. The earliest pivoted-blade fan to come to the attention of the Radio Development Section was made by the Sperry Gyroscope Company, but it proved unsuccessful, due to mechanical weakness. It was, however, the forerunner of very successful fans, and serves to illustrate the general principle on which all operate. The blades are mounted on bearings and are capable of rotating through a considerable angle. Centrifugal weights are mounted on arms attached to these blades and tend to turn them in the proper direction to increase the pitch. A resisting spring and necessary hub complete the mechanism.

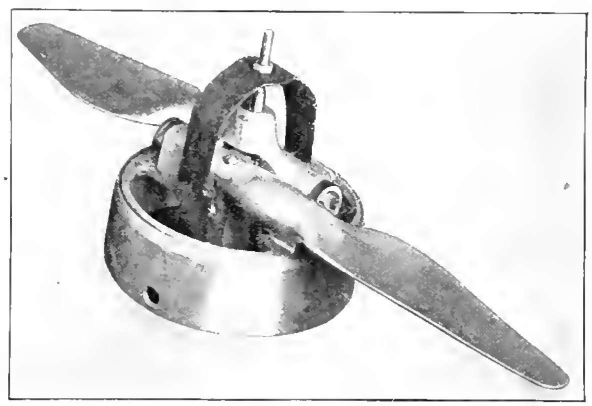

FIG. 7 TYPE FA-4-A. VARIABLE-PITCH AIR FAN

The first model to perform satisfactorily was designed by Mr. Thomas Slate, of the American Mechanical Improvement Company, of Washington, D. C. The very great improvement over the fixed-blade fans then in use made the production of this fan highly desirable, and it was undertaken at once under purchase specifications as follows:

Operating air-speed limits	45 to 300 m.p.h.
Normal speed	4500 r.p.m.
Speed variation less than	Plus or minus 4 per cent
Overspeed test	8000 r.p.m.

It was, of course, realized that this fan was by no means in its final form, and work toward improving it and providing new sources of production was carried on as rapidly as possible. One of the objections to the original design was that the particular mechanism used caused the centrifugal force to increase as the sine of twice the angle, while the spring restraining force increased according to a straight-line relation. In the second successful design this was corrected by the use of a special linkage between spring and blade which modified the curve of spring resistance to fit that of the centrifugal weight. Fig. 7 shows one of these fans and Fig. 8 its performance. In this as in many other cases of radio develop-

ment work, the design was conceived and outlined by the Signal Corps engineers and the details worked out at once by the manufacturer (in this case the American Propeller and Manufacturing Company) in a form ready for immediate production.

The third successful design of variable-pitch air fan was the work of Mr. Pinaud, of the Des Lauriers Aircraft Corporation, and differs very radically from those previously described. It uses

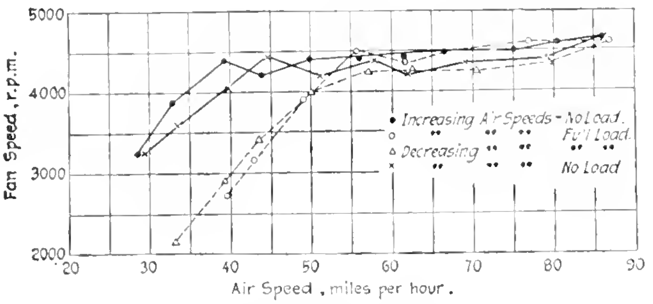

FIG. 8 PERFORMANCE CURVES OF TYPE FA-4-A AIR FAN (Diam., 20 in.; pitch variable)

only one blade, and its principal advantage is that by ingenious counterbalancing practically all strain is taken off the bearings whereas in other forms the thrust bearings must carry a very considerable load—both radial and thrust—due to the high speed of rotation, and the unbalanced designs of the blades. Friction, of

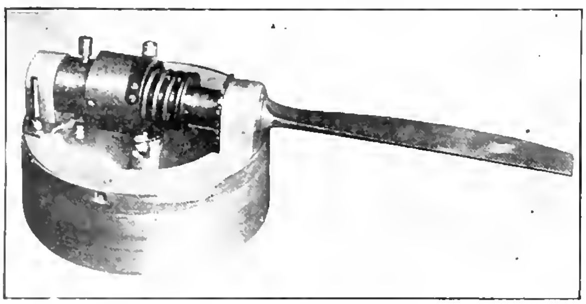

FIG. 9 TYPE FA-8, VARIABLE-PITCH AIR FAN, SINGLE-BLADE, 200-WATT

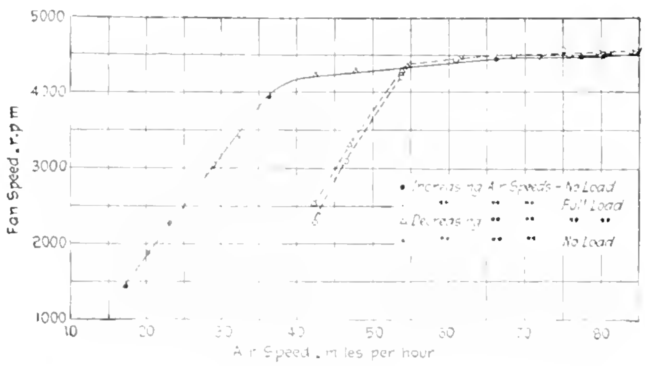

FIG. 10 PERFORMANCE CURVES OF TYPE FA-8 AIR FAN (Swept diam., 20 in.; pitch variable)

course, results in considerable "lag" in the performance of the fan. The mechanical construction of the Pinaud fan is also a considerable improvement over its predecessors in simplicity and ease of manufacture. Figs. 9 and 10 show its construction and performance.

HEAD-RESISTANCE TESTS

A demonstration of the value of the regulating air fans in reducing head resistance was made by the direct test of a complete radio-telegraph transmitting set in the wind tunnel. A run was first made with the set equipped with a fan hub and nose cap but no blades; then a second run was made with a fan operating normally with the generator both loaded and running light, and finally a third run was made with the fan blades locked at several values of pitch. The results of these tests are shown in Fig. 11, from which the following conclusions may be drawn:

The head resistance of the set fully loaded in an air stream of 75 miles per hour is 6.5 lb. At this air speed the resistance of the blades alone equals the resistance of the body, after which the resistance of the blades remain nearly constant, while that of the body increases as the square of the air speed. The body alone has 5 lb. head resistance at an air speed of 90 miles per hour, and at the usual ratio of 1/8 hp. from the engine per lb. of head resistance, this requires 0.36 hp. from the engine. On a basis of 20 lb. in the fuselage per hp. from the engine, the set would weigh 13 lb. more than it now does and still be no more load on the

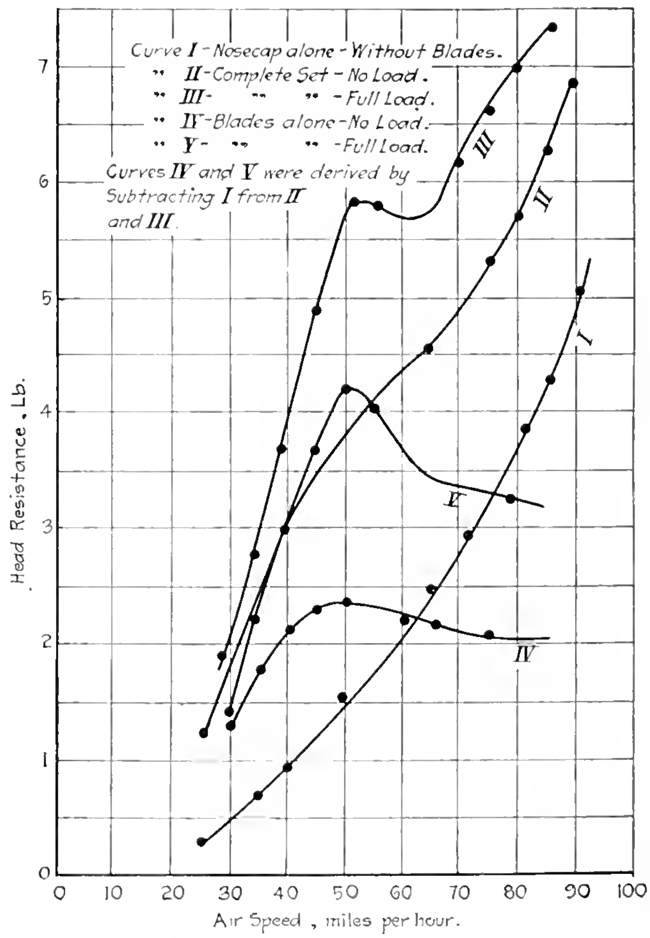

FIG. 11 HEAD-RESISTANCE CURVES, TYPE FA-4 AIR FAN

engine provided it was mounted in the fuselage and obtained its power directly from the engine. This emphasizes the desirability already mentioned of obtaining all electric power by direct drive from the engine rather than from air fans where it is possible to do so.

AIRFOIL TESTS ON BLADES FOR REGULATING AIR FANS

In designing blades for regulating air fans, the effect of wind pressure in producing torque around the blade axis has been questioned, and obviously such an effect might seriously interfere with the performance of the fan. To obtain data on this point tests were made on blades from a fan of the type shown in Fig. 7, using an airfoil balance.

The results thus obtained show that this effect is negligible so far as practical designing is concerned.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of MECHANICAL ENGINEERING by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

Threads and Thread Gages[1]

TO THE EDITOR:

The war brought with it many new problems, among which were the building up quickly from raw labor of a force capable of attaining and maintaining a high standard of work upon an emergency production basis, and the organization and education of a competent force to inspect the work done.

A cause of misunderstanding has been the fact that the inspection force, not being well grounded in the fundamentals of manufacture, have thought the manufacturer lax in his methods or deficient in knowledge, and the manufacturer on the other hand has taken it for granted that the inspector was familiar with manufacturing methods and has not taken pains to explain manufacturing difficulties.

The greatest of our troubles in this respect has probably been the question of threads and thread gages. Threads at best are a debatable and theoretical subject of which more is guessed at than known, and of which figures do not tell all that should be said. At the beginning of the war the Bureau of Standards was asked to devise means of checking gages, and with its usual thoroughness at once developed excellent means of measurement; but unfortunately no gages that were manufactured could pass their tests.

This, however, was remedied in time, but our ability to measure still outstripped our ability to make gages and much time and money was wasted. Eventually such progress was made in thread-gage manufacture that today almost perfect gages are turned out; but to what end? Threads have not improved nor the method of making them, and again in our gages we have far outstripped our ability to make threads. There seems to be no reason for making the production of threads more costly than at present, since they are satisfactory as regards strength; and whether they are or are not satisfactory otherwise the gage does not definitely tell us.

In no other place that I can at present recall is the gaging of a piece made more severe than the service required by the use to which it is to be put. For instance, if we are to measure the outside diameter of a cylindrical body, we do not use a cylindrical gage the height of the piece and set the piece in it; we use a snap gage or a ring gage. In the case of a thread, however, we make our gages at least one diameter thick—in some cases more—and while we use a wrench for ultimately screwing down a bolt and usually throw it out if it goes in by hand, we expect every bolt to go in the thread gage by hand and without force and make no allowance in our gages for final screwing down, thus defeating the very object we are striving for, to wit: a good fitting male and female thread. I do not think it an exaggeration to say that if we took a bolt and nut that fitted perfectly in the gages, we would reject both when we used them. The inaccuracies or burrs are what make the apparent good fit.

Further, we do not cut the same thread upon different kinds of material with the same die. In manufacturing we have to deal with open-hearth and bessemer steel, brass and copper, which neither tap nor thread the same. Should we not then make our gages different for each material? The number of good threads in a given lot of pieces made with the same die or tap is dependent first upon the nature of the material used; second, the tolerance allowed; third, the method of relieving threading tools; fourth, the relation of the weight of the die and the nature of the piece it is cutting; fifth, the mechanical means used to cut; sixth, the nature of lubricant used and uniformity is thus a matter of percentage.

In a mechanical sense the only part of the thread that is vital is at or near the pitch line. Still, we have insisted upon 100 per cent height of thread because the draftsman so pictured it and it has been necessary to make taps and dies to cut as the gage demanded, rather than to make them as they should be.

Another fact to be considered is that in most other things we usually gage only finished parts. We never think of holding to close limits on a roughing cut, but still we insist upon doing so on a thread which is precisely a rough cut as it is made in a single cut with a tool which fundamentally lacks necessary clearance, rake, and rigidity.

Another point which shows the weakness of our thread-gaging methods is that many threads enter the maximum gage with difficulty the first time and shake the second time. The answer to this, of course, is that the threads are rough at first and fit the gage snugly. In the process of trying them in the gage, however, they become smooth and where gaged a second time are a loose fit. This is more particularly true of brass. Also, using a ring gage often takes off the point of the thread so that it will not pass the maximum-diameter test. I know of a firm that lost thousands of brass pieces with a fine thread by their being pressed into a ring gage, and it took very little cocking or pressure to do it.

While we must maintain standards, we do not need watchmaking on locomotives. Traction engines are built differently from automobiles and while both use practically the same parts, the gaging that may be vital on an automobile is a non-essential on traction engines.

In practice it is usually the difference in the lead between the male and female thread that makes the fit. We make our gages accurately in this respect and then find it is impossible to procure taps and dies anywhere near as accurate.

The question of lead and angle has never been considered so important as since we entered the war. I think it may be stated without exaggerating that there are not a hundred lathes in the United States having lead screws of identically the same characteristics, considering as a basis the degree of accuracy used by the Bureau of Standards in measuring gages. This being so, it follows that it is impossible to get taps from different makers, or even from the same maker, which will check up accurately with a gage made by some one else, and a lead adjuster does not entirely cure this fault.

With the introduction of the wire method of measuring, it is now necessary in cutting a thread to figure out in abstruse mathematics the angle the thread tool should have in order to generate a thread of the required angle and pitch diameter.

The question naturally arises, then, Are we not making our threads to conform to the results secured by wire measurements, and misleading ourselves as to the angle and pitch diameter obtained? Are we not taking the wire system as an end and making our threads conform to the wire rather than using the wire as a means of measurement? In other words, we do not know whether we are getting the correct angle and pitch diameter with our wires, but we make our threads conform to them, nevertheless, and i believe that the wire system of measurement should be used for duplication only and not to set standards.

When the cross-section of the thread of a gage is projected on a screen the surface is shown to be full of hills and valleys even when ground—quite often the tooth is rounded. The object of the projectoscope is to indicate whether or not the tops of these hills constitute the desired angle. It is obvious that in using

[1] Contributed as a discussion of the subject of Threads and Thread Gages presented at the Annual Meeting, December, 1918.

wires one may rest in a valley and the other on top of a hill—which shows the fallacy of attempting to say that a thread is 0.0002 in. or 0.0003 in. undersize or oversize on the pitch diameter. We do not know that we are measuring on the pitch diameter, which is simply a mathematical point of departure where two theoretical circles touch.

It may be asked why a thread is not as readily measured on the pitch diameter by the wire method as is a gear, where the method originated. The answer is that on a gear the wire has a long bearing on a finished, smooth surface with the tool marks parallel with the wire and much finer in proportion, giving it a true seat. It would not be attempted to measure helical or bevel gears by this method. It is obvious that the only way to do this would be with a ball and not a wire. This same is true of helical threads.

Many thread gages have been rejected because they were 0.0002 in. off on the pitch line, and when this occurs it begins to tax our credulity as to the ability of man to make these measurements, since we know that on a straight, flat piece two men can seldom measure within 0.0002 in., even with the same micrometer, the difference being due to the difference in pressure and feel. Of course here again we must not confuse the facilities of the Bureau of Standards with those available to the tool manufacturer doing war work.

When we consider that 0.0001 in. on the wire used for measuring a 32-pitch thread makes a difference in angle of 0.5 deg., we can see to what impossible refinement we are carrying things when gages were rejected that showed an error of more than 10 min.

The question of the maximum diameter is always a subject of discussion and dispute. Most drawings call for a theoretical 100 per cent thread or leave it to be inferred. In practice in the past we have been able to secure 75 to 85 on bessemer rod; from 85 to 90 with open-hearth rod and 90 to 95 on good brass. With the thread miller it is possible to get 75 to 85 per cent of pieces with 100 per cent thread, but fine threads usually require burring; and it is also in some cases possible to get a 100 per cent thread by cutting a slot in the bottom of the thread on the tap, thus allowing the metal to flow.

Having hypothetically gone to the practice of milling our threads and having secured thereby what by individual measurements we call a 100 per cent thread of the proper lead and pitch diameter; and having also secured from the Bureau of Standards a gage as near perfect as they can manufacture, what will the gage tell us with regard to the thread? It does not tell us whether the thread angle is too small nor whether the pitch is correct. It does not tell whether the outside diameter is too small. It simply tells us three things: (1) whether the outside diameter is too great, (2) whether the bottom of the thread is oversize, and (3) whether the lead is correct.

I am assuming that the above was a maximum gage. Adding a minimum gage would establish only one thing more; i.e., the minimum outside diameter.

I have stated that if we had perfect gages and a perfect nut and bolt, we would reject them when we came to use them. So, logically, if perfection is not satisfactory, less than perfection must be. We may lay it down as an axiom that two threaded pieces, the angles of the threads of which are the complement of each other, cannot, if made correctly, produce a tight fit. What is required is to place enough metal on the male member to fill the female threads, and by this process any desired fit may be secured, regardless of tolerance.

Gen. Supt. Wagner Elec. Mfg. Co.

St. Louis, Mo.

Laying a 6-ft. Water Pipe Across Passaic River

To the Editor:

An interesting problem in mechanical and civil engineering may be observed at Delawanna, N. J. (nine miles from Hoboken via D., L. & W. R.R.), where the Jersey City Water Department is laying a new 6-ft. diameter water-supply pipe across the Passaic River.

The pipe, which is built of 5/8 in. steel plate, is to be riveted together and tested hydraulically before being placed in position.

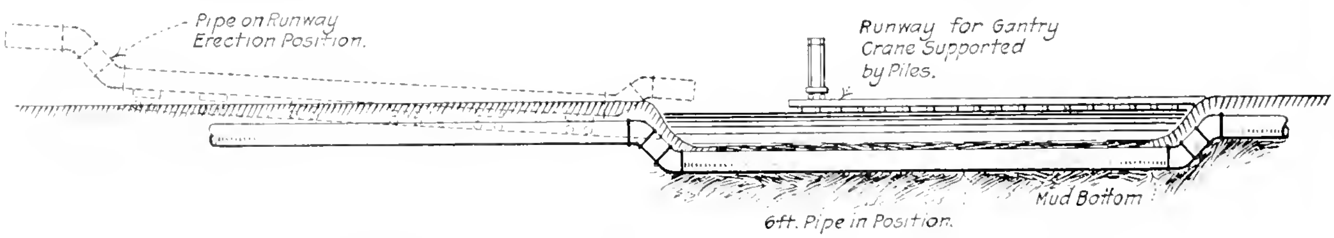
On the west side of the river and sloping gradually toward it, a narrow-gage track has been laid. About two-thirds the distance across the river, which at this point is about 200 ft. wide, two parallel rows of piles to support a gantry crane have been driven. The gantry could not be carried all the way across the river because navigation had to be kept open.

The plan of operation is to build the pipe on the wheeled carriages placed on the narrow-gage track, and then gradually to move it into the river, supporting it partly by the crane, by the traveling carriages, and by floating.

When the correct position has been reached the pipe will be sunk to its proper level, set and connections made to the existing pipe on each bank of the river. The pipe to be handled is about 250 ft. in length and weighs in the neighborhood of 65 tons.

Robt. Lacy.

Washington, D. C.



Method Employed in Laying a 6-Ft. Water-Supply Pipe Across the Passaic River

Lubrication of Air Compressors

To the Editor:

The report of Mr. H. V. Conrad, page 384 of the April issue of Mechanical Engineering, concerning the lubrication of air compressors is excellent, and should be given serious consideration by the owners and operators of such machinery.

If I may add a suggestion in this connection, I would strongly advocate the use of a suitable oil separator to be placed on the discharge line between the air cylinder and air receiver, and so arranged as to permit the blowing out of the entrapped oil at regular intervals, say once each day.

An oil separator such as is used on the gas-discharge lines of ammonia compressors would meet the requirements.

By following this plan most of the oil passing from the air-compressor cylinders will be entrapped and prevented from getting over to the air receiver, and this oil when drawn off can usually be used to advantage somewhere about the plant if properly filtered.

Another thing in this connection: It would help matters to place on the drain of the air receiver a suitable trap to automatically drain it of moisture and oil. This trap would, of course be similar to the ordinary steam trap, except that its valves should be designed for the character of the work they are to perform. It should be by-passed, permitting hand draining of the receiver in case trap repairs are to be made.

Atlanta, Ga.

WORK OF THE BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation in the form of a reply is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING, The Journal of the Society, in order that any one interested may readily secure the latest information concerning the interpretations.

Below are given the interpretations of the Committee in Cases Nos. 228-235, inclusive, as formulated at the meeting of April 25, 1919, and approved by the Council. In this report, as previously, the names of the inquiries have been omitted.

CORRECTION

Case No. 223: Through an oversight certain typographical corrections in Case No. 223 which were ordered by the Boiler Code Committee were overlooked in their publication in MECHANICAL ENGINEERING. The reply in this Case should read as follows:

Reply: Under the requirements of Par. 239, the furnace will not require staying. There remains, therefore, only the crown sheet, top head of the boiler and the flue to be considered. Par. 203*d* or the latter part of Par. 216 are applicable to the crown sheet and top head, if formed from flat sheets. If, on the other hand, the crown sheet and top head are dished, the maximum allowable working pressure is calculated from Par. 195. Par. 241 applies to the flue.

CASE NO. 228

(In the hands of the Committee)

CASE NO. 229

Inquiry: Is it not permissible under the requirements of the revised edition of the Boiler Code (Edition of 1918) to equip a boiler with safety valves set for the pressure for which the boiler is designed, even though the boiler is to be operated at a pressure lower than this maximum allowable working pressure? It frequently occurs that a boiler will be built for a certain pressure, but will be operated initially at a lower pressure and the pressure increased later, and it would obviously be of great convenience to boiler manufacturers if the safety valve could under such conditions be set for the maximum allowable working pressure.

Reply: There is no way by which the exact safety valve capacity can be determined without knowing the pressure under which the boiler is to operate. Pars. 270, 271 and 274 give the rules for determining the capacity under the construction and after the operating pressure is known.

CASE NO. 230

(In the hands of the Committee)

CASE NO. 231

Inquiry: Is it necessary under the requirements of the Heating Boiler Section of the Code, to construct boilers which exceed 60 in. in diameter but are to be operated at pressures not exceeding 15 lb., according to the requirements for power boilers?

Reply: Part I, Section II of the Boiler Code, does not specify that heating boilers exceeding 60 in. in diameter, need to be built in accordance with power boiler rules. The only special requirement of steam heating boilers over 60 in. in diameter carrying not to exceed 15 lb. per sq. in., is that under Par. 341, the longitudinal joint shall not be of lap-seam construction.

CASE NO. 232

Inquiry: Is it necessary that the bolting face of a pressed steel flange as shown in Fig. 1 riveted to a boiler shell for use

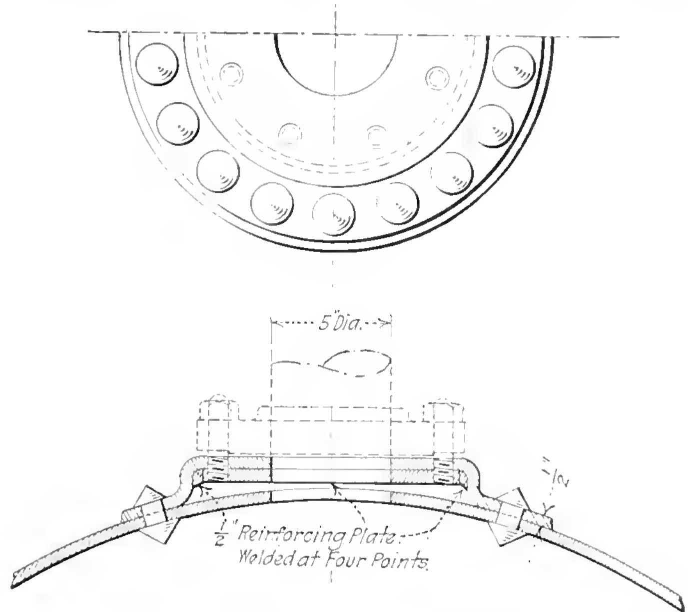

FIG. 1 PRESSED STEEL FLANGE FOR USE AS BOILER NOZZLE

as a nozzle, must comply with the requirements for flanges given in Tables 16 and 17? Should the thickness of such a steel flange conform to that required in these tables for cast iron?

Reply: It is the opinion of the Committee that any form of construction of flange within the stress limits used in boilers specified in the Code may be used for a flange which is attached to the boiler. The diameter of bolt circle and requirements as to number and size of bolts, should conform to the requirements of Tables 16 and 17.

CASE NO. 233

Inquiry: Do the requirements of Par. 258 of the Boiler Code, respecting the reinforcement of handhole openings, apply in general or only to handholes placed in boiler shells?

Reply: The requirements of Par. 258 are intended to apply to handholes placed in the cylindrical sheets of shells or drums.

CASE NO. 234

Inquiry: Is it necessary that washers used between the curved surface of the dished head of the drum of a water tube boiler and the nuts of threaded stays, be of cast steel, or may they be of cast or malleable iron? These washers which are of special wedge shape, are not exposed to any high heat, but are merely used in compression.

Reply: It is the opinion of the Committee that the washers shall be made of wrought or cast steel, or wrought iron.

CASE NO. 235

Inquiry: Is it permissible under the Rules of the Boiler Code to form an outlet nozzle on the steel pipe header of a boiler by inserting a nipple through a hole bored in the side of the pipe header for a driving fit, and flaring the interior projecting end, and then subsequently welding to the header around its outside circumference for steam tightness, the metal in the pipe header being of a lesser thickness than that required to make an expanded joint?

Reply: It is the opinion of the Committee that this method of of forming an outlet nozzle on a pipe header, does not meet the requirements of the Rules in the Boiler Code, which sanction the use of autogenous welding only where the strain is carried by other construction conforming to the requirements of the Code.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

Research Needs

Dr. W. R. Whitney, Director of the Research Laboratory of the General Electric Company, writes regarding the need of developing research men and the importance of holding those who have demonstrated their ability in research in this field. He suggests the possibility of the Society's aiding by financial support in the following way:

> I have also felt, in the case of our Chemical Society, that if it could raise the money to insure at least one pure research investigator a year, it could scarcely find a better way of advancing the science. I thoroughly believe that there is nothing which could do as much good for American science as to pick out a few good, young students, and by cold cash insure their continuance in pure and independent scientific work. This might be called the personal method, but I am sure that I have already noticed, in watching men, that a good man can do wonderfully good work in the advance of science or engineering if it can be arranged that he devote his entire attention to it with either a fair outlook or an assurance of safety on his part.

Erratum

In the description of the Thermal Testing Plant of the Experiment Station of Pennsylvania State College on page 464 of Mechanical Engineering for May, the statement that the Tagliabue thermostats hold room temperatures within 5 deg. should read 0.5 deg.

A—Research Results

Cement and Other Building Materials A1-19 Tests on Kansas Sands for Use in Mortar and Concrete, by R. A. Seaton and I. I. Taylor. Bulletin No. 3, Engineering Experiment Station, Kansas Agricultural College. Address Director A. A. Potter.

Results of experiments show that all samples met the requirements of the joint Committee on Concrete and Reinforced Concrete from the four national engineering societies. Thirty-two of fifty-two samples have to be used with a small excess of cement. Only one sand had more than 6 per cent of its sample pass through a 100-mesh sieve. The sands in general were well graded.

Cement and Other Building Materials A2-19 An Investigation of Blended Portland Cement, by E. S. McCandliss and H. H. Armsby, School of Mines and Metallurgy, University of Missouri. Address Director, Rolla, Mo.

Electric Power A1-19 Electric Cooking Appliances, R. G. Kloeffler. Bulletin No. 9, Engineering Experiment Station, Kansas Agricultural College, Manhattan, Kan. Address Dean A. A. Potter.

Advantages of electric cooking: safety, cleanliness, convenience, excellent results. First appliances exhibited in London, 1891. A cooked banquet to Lord Mayor of London, 1894.

$$\text{Efficiency} = \frac{\text{change in temperature} \times \text{lb. of water}}{3415 \times \text{kilowatt-hours.}}$$

Electric Irons: 0.97 kw-hr. for ironing wash for family of two; 1.25 kw-hr. for 70 pieces, family of six. Iron disconnected $28\frac{1}{2}$ per cent of time.

Electric Toasters: 0.11 kw-hr. to make eight pieces of toast.

Coffee Percolators: about 0.08 kw-hr. to make five cups of coffee; efficiency 72 per cent.

Electric Grills: 0.10 kw-hr. for eight pieces of toast; efficiency 39 per cent.

Chafing Dishes, efficiency 60 per cent.

Immersion Water Heater, efficiency 80 per cent.

Cost of breakfast of 5 cups coffee, 4 slices of toast, 2 slices of bacon, 2 fried eggs, 0.19 kw-hr.

Electric Ranges: Efficiency range from 32 to 60 per cent.

Cost of cooking for a week (comparative values): 20.7 kw-hr., 320 cu. ft. of gas, 70.25 lb. of coal, 2 gal. of kerosene.

Foundry Equipment, Materials and Methods A1-19 Silica Refractories. Factors affecting their quality and methods of testing the raw materials and finished ware. Technologic Papers of the Bureau of Standards No. 116. Address Director S. W. Stratton, Bureau of Standards, Washington, D. C.

The work of this paper was carried out to obtain by simple, accurate means the degree to which the amorphous silica is gradually transformed to crystal forms of lower specific gravity when bricks are burned. Points concerning raw materials and methods of manufacture are touched upon as possible improvements. Molding with a pressure of 1500 lb. per sq. in. after mixing of sized materials in a batch mixer. The experiments show that the best method to burn is to raise the temperature to 1250 deg. cent. in the usual manner and then keep it between 1250 and 1350 deg. for several days, at the end of which time it is raised until the Orton pyrometric cones from 18 to 20 bend over. The specific gravity and porosity of most of the leading varieties of silica brick have been determined. They vary between 2.650 and 2.270 with an average of 2.384. The porosity varies from 22.6 to 31.5 per cent. The investigations show that the specific gravity between 2.65 for quartz and 2.270 for tridymite crystals indicates the degree to which the brick has been burned.

Foundry Equipment, Materials and Methods A2-19 Molding Sand. A method to determine the optimum water content of molding sands consists of adding an excess of water and whirling the mixture in a centrifuge. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Fuels—Gas, Tar and Coke A1-19 Preliminary Studies of Missouri Cannel Coal, by H. L. Dunlap. School of Mines and Metallurgy, University of Missouri, Rolla, Mo. Address Director.

Iron and Steel A1-19 Purification of Magnetite Ore Containing 4 per cent Sulphur—Commercially Successful Process of Purification to 0.10 per cent. Pittsburgh Testing Laboratories, Pittsburgh, Pa.

Mathematics A1-19 Physical Quantities. A Relation Connecting the Derivatives of Physical Quantities. Applying dimensional calculations used in wind tunnels to other problems as those in predicting errors in instruments. Scientific Paper, Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Metallurgy and Metallography A1-19 Aluminum and Its Light Alloys. Bureau of Standards Circular No. 76. Bureau of Standards, Washington, D. C. Address Director.

Metallurgy and Metallography A2-19 Bibliography on Roasting, Leaching, Smelting and Electrometallurgy of Zinc, by H. L. Wheeler. School of Mines and Metallurgy, University of Missouri, Rolla, Mo. Address Director.

Metallurgy and Metallography A3-19 The Effect of Addition Agents in Flotation, by M. H. Thornberry and H. T. Mann. School of Mines and Metallurgy, University of Missouri, Rolla, Mo. Address Director.

B—Research in Progress

Air B1-19 A Commercial Method for the Measurement of High-Pressure Air Flow (100 lb. per sq. in. gage). H. S. Dickerson, School of Mines and Metallurgy, University of Missouri. Address Director, Rolla, Mo.

Apparatus and Instruments B3-19 Measuring Device for Effective Diameter of Thread Ring Gages. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments B4-19 Lead-testing Machine for Threads. Improvement of apparatus shown in Figs. 3 and 4, page 412, of Mechanical Engineering, April, 1919. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments B5-19 Balanced Micrometer Holder. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments B6-19 Specific Gravity of Finely Powdered Materials. A new method to obviate difficulty due to the presence of air. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Chemistry, Organic B1-19 Preparation of Anhydrous Oxalic Acid by Use of Buffalo Vacuum Self-Drier. W. D. Turner and P. D. Wilkinson, School of Mines and Metallurgy, University of Missouri. Address Director, Rolla, Mo.

Chemistry, Organic B2-19 Preparation of Tri-methyl-amine by Means of J. P. Devine Autoclave at 650 to 700 Lb. per Sq. In. from Methyl Alcohol and Ammonium Chloride. W. D. Turner and B. G. Nichols, School of Mines and Metallurgy, University of Missouri. Address Director, Rolla, Mo.

Economics B1-19 Cost and Accounting. System for a Machine Shop. Worcester Polytechnic Institute, Worcester, Mass. Address Prof. W. W. Bird.

Electric Power B2-19 The Efficiency of Coal, Kerosene, Gasoline and Electric Water Heaters. Engineering Experiment Station, Kansas Agricultural College. Address A. A. Potter, Manhattan, Kan.

Heat B4-19 Resistance of Air to the Transmission of Heat. Engineering Experiment Station, Kansas State Agricultural College. Address Dean A. A. Potter, Manhattan, Kan.

Heat B5-19 Heat Transmission Through the Various Insulating Media. Engineering Experiment Station, Kansas Agricultural College. Address Dean A. A. Potter, Manhattan, Kans.

Hydraulics B2-19 Weir Coefficients. Determination of coefficients for 10-ft. weir. Worcester Polytechnic Institute, Worcester, Mass. Address Prof. C. A. Allen.

Internal-Combustion Motors B4-19 Temperature of Oil Films and Various Parts of Engines During Operation. Determination of flame propagation and temperature within cylinder. Preliminary measurements on single-cylinder Liberty engine. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Internal-Combustion Motors B5-19 Fuel Consumption of Ford Engine with Different Adjustments of Stock Carburetors to Demonstrate Fuel Saving. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Leather and Glue B1-19 Leather Belting. Relative capacity of various materials to transmit power. Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa. Address Director R. F. Bacon.

Lubrication B3-19 An Investigation of Various Cylinder Lubricating Oils. Engineering Experiment Station, Kansas Agricultural College. Address Dean A. A. Potter, Manhattan, Kan.

Machine Tools B1-19 Twist Drills. Point Thinning of Twist Drills. Used to reduce thickness of web so as to reduce thrust without weakening drill. Worcester Polytechnic Institute, Worcester, Mass. Address Prof. W. W. Bird.

Machine Tools B2-19 Proper Drill Speeds for Given Feeds. Worcester Polytechnic Institute, Worcester, Mass. Address Prof. W. W. Bird.

Metallurgy and Metallography B1-19 Determination of Cadmium in Zinc by Means of a Microscope. H. T. Mann and H. P. Gill. School of Mines and Metallurgy, University of Missouri. Address Director, Rolla, Mo.

Metallurgy and Metallography B2-19 The Relation of Exact Pyrometric Control of Heat-Treatment Furnaces to the Efficiency of Drill Steel. C. Y. Clayton, School of Mines and Metallurgy, University of Missouri. Address Director, Rolla, Mo.

Road Materials and Equipment B2-19 Tests on Kansas Road Materials. Engineering Experiment Station, Kansas State Agricultural College. Address Dean A. A. Potter, Manhattan, Kan.

Steam Power B2-19 Coefficient of Friction of Low-Pressure Steam in Pipes. University of Michigan, Ann Arbor, Mich. Address Dean M. E. Cooley.

Transmission B5-19 Minimum Center Distance of Pulleys for Belt Drives. Relation Between Elasticity, Tension and Time Element. Worcester Polytechnic Institute, Worcester, Mass. Address Prof. W. W. Bird.

Transmission B6-19 Windage of Belt Drives. Loss of Power Due to Skin Friction and Variation With Speed. Worcester Polytechnic Institute, Worcester, Mass. Address Prof. W. W. Bird.

C—Research Problems

Heat C1-19 Transmission of Heat Through Cast-Iron Pipes in Annealing Furnaces. Transfer of heat from waste gases at 1000 to 1400 deg. fahr. moving with a velocity of 1000 to 2000 ft. per min. Temperature of furnace between 300 and 500 deg. fahr. Address G. L. Ostgren, New Jersey Zinc Co., 55 Wall St., New York City.

Light C1-19 Optical Surfaces. Improved methods of polishing optical surfaces, including metals, glass, rubies, etc. Address F. G. Pease, Mt. Wilson Solar Observatory, Cal.

Photography C1-19 Speed of Photographic Plates. Mt. Wilson Solar Observatory is desirous of having plates of higher speed. The time required for exposure with 72-in. reflector is 1½ hours. F. G. Pease, Mt. Wilson Solar Observatory, Cal.

Properties of Engineering Materials C1-19 Steam Packings. Relative value of steam packings, red packings, black packings, packings with more than 30 per cent rubber. Asbestos rubber packings. Frederick Dannerth, 325 Academy St., Newark, N. J.

Properties of Engineering Materials C2-19 Elastic Limit of Small-Size Commercial Drawn Tubing of Various Materials in Tension, Compression and Torsion. Harrison Safety Boiler Works, Philadelphia, Pa.

Properties of Engineering Materials C3-19 Hysteresis of Metals Under Reversed Stress and Torsion. Harrison Safety Boiler Works, Philadelphia, Pa.

Properties of Engineering Materials C4-19 Fatigue of Metals Made in Small Tubes. Harrison Safety Boiler Works, Philadelphia, Pa.

D—Research Equipment

Aircraft D1-19 Wind Tunnels, Washington Navy Yard. One tunnel 8 ft. square with maximum velocity of 80 miles per hour. Liners can reduce this to 8 x 4 ft. or 4 x 4 ft., giving wind speeds of 150 or 200 m.p.h. Tunnel equipped with Eiffel-type balance of 30 lb. capacity. A three-dimensional balance is being designed. One wind tunnel is 4 ft. square with maximum wind speed of 65 m.p.h. Small tunnel equipped with balance of Curtiss Engineering Corporation, capacity 20 lb. Address Commander McEntee, Navy Yard, Washington, D. C. (see Research Personal Notes, *Marine Engineering E1-19*).

Pittsburgh Testing Laboratory D1-19 This laboratory is equipped for chemical and physical tests in industrial chemistry and mine operation; tests of ores, fuels and raw materials; cement, sand and stone and concrete structures; inspection of asphaltic and other paving materials with portable

laboratories; inspection at mills and shops for bridges, buildings, shops, cars, locomotives, machinery, rails and inspection of steel and cast-iron pipes; testing of power plants and pumping plants. Address Pittsburgh Testing Laboratory, Pittsburgh, Pa.

University of Illinois D1-19 The equipment of the mechanical laboratory.

Steam Boilers
- 210-boiler hp. Heine boiler
- Foster superheater of 3100 sq. ft.
- Sturtevant economizer
- Kewanee down-draft smokeless house-heating boiler
- Small Arco cast-iron steam-heating boiler
- One Mercer cast-iron sectional steam-heating boiler

Steam Engines
- 7 x 10-in. and 10 x 12-in. Chandler & Taylor cross-compound engine with surface condenser
- Two 10 x 10-in. Ideal engines
- One 8 x 12-in. Meyer automatic engine
- One 8 x 18-in. Murray Corliss engine
- One 12 x 24-in. Allis-Chalmers Corliss engine belted to a 100-kw. generator
- One 60-hp. Kerr turbine
- Two 100-kw. Curtis turbo-alternators

Pumps
- One 300-gal. 150-lb. Fairbanks pump
- One 140-gal. two-stage DeLaval turbo pump

Main Steam Piping
- Steam piping is arranged to deliver saturated and superheated steam to any of the above units

Small Power-Plant Group
- 25-hp. portable boiler with 7 x 10-in. Atlas steam engine with feedwater heater, boiler-feed pumps, water meter

Heating and Ventilation
- Four-unit steam-radiator testing plant
- Experimental hot-blast heating unit with each section arranged for individual determination of condensation
- Warren, Webster & Co. air washer with temperature and humidity control
- Fans with facilities for making traverses of air duct and with fan driven by Sprague electric dynamometer
- Heat-transmission plant for finding heat through building materials
- Warm-air-furnace testing plant equipped for measuring temperatures, air velocity, effect of register faces, leaders and stacks

Air Compressor
- Two-stage 12¼-in. and 18¼ x 12 in. Ingersoll-Sargent compressor

Refrigeration Equipment
- Ten-ton York ammonia compressor
- Ten-ton Vogt absorption refrigerating machine with ice-making equipment and apparatus for measuring refrigerating effect

Internal-Combustion Engines and Gas Producer
- Two four-cylinder motors
- One six-cylinder motor
- One Sprague dynamometer of 150-hp.
- One 10 x 19-in. Otto engine
- One 5¾ x 12½-in. Otto engine
- One 9 x 9-in. Bogart engine
- One 9 x 10-in. Mietz and Weiss engine
- One 10 x 20-in. tandem Sargent engine
- One 75-hp. Smith producer

University of Kansas D1-19 The equipment in the mechanical laboratory of the University of Kansas is as follows:

Steam Equipment
- One 100-hp. Stirling boiler, hand-fired, with induced draft
- One superheater
- One 10 x 24 x 30-in. cross-compound Corliss engine
- One 20-hp. DeLaval turbine driving circulating-water pump
- One 75-hp. Ball engine, high-speed
- One Wheeler condenser, 500 sq. ft., with electrically driven wet vacuum pump and Mullen dry vacuum pump
- One equipment for demonstrating steam equipment and for exercises on same
- Power-developing units, including high-speed steam turbine, cross-compound high-speed engine, condensing, and boiler equipped with stokers available for commercial tests

Gas Equipment
- One 75-hp. tandem single-acting gas engine
- One 5-hp. Olds gas engine
- One 12-hp. I. H. C. oil engine
- One Ford automobile engine
- One 75-hp. Smith gas producer

Refrigeration
- One 5-ton Cleveland ammonia compressor

Small Equipment
- Gages, indicators, oil and friction testing machines, gas-analyzing apparatus, fuel calorimeters, steam calorimeters, speed counters, etc.

University of Missouri, School of Mines, D1-19 The Laboratory of the School of Mines, University of Missouri, includes the following equipment:

Boilers
- Four 130-hp. Heine safety boilers with soot blowers and measuring apparatus.

Engines and Generators
- 10-hp. Wickes boiler and engine plant
- 75-kw. Erie-Ball engine and Westinghouse d.c. generator
- 50-kw. Ideal engine with Westinghouse d.c. generator
- 50-kva. General Electric marine-type engine with a.c. generator
- 10-kw. General Electric turbo-generator
- 30-hp. Kerr steam turbine
- 9 x 14-in. Brownell engine
- 5 x 7-in. Davis & Rankin engine
- 21-hp. Otto engine
- 3-hp. Ferro gas engine
- 8-hp. Bessemer gas engine
- 6-hp. Continental automobile motor

Pneumatic Equipment
- One Laidlaw-Dunn-Gordon air compressor
- One Rand Imperial air compressor
- One Sullivan air compressor
- One 36-in. Sirocco blower
- One 72-in. Buffalo fan
- One 62-in. Buffalo blower
- Air tanks.

Testing Machines
- 200,000-lb. tension, compression and bending machine
- 60,000-lb. Olsen torsion machine
- 50,000-lb. Riehlé machine

Mining Equipment
- 42-in. furnace with coal, gasoline and coke
- 20-in. blast furnace
- One gyratory breaker and one Dodge breaker
- One pair of rolls
- Two plane shaking screens, three trommel screens
- One duplex Callow belt screen
- One 3½-ft. Huntington mill and one three-stamp mill
- Two Vezin samplers.
- One Richards pulsating classifier, three-spigot cone classifier, four-spigot classifier, Tamarack classifier
- Four settling cones
- Three 5-cell Herz jigs and one pulsator jig
- Tables for sands: one Card, one Deister-Overstrom, one James, and two Wilfley
- One 4-ft. Frue vanner
- One 5-ft. Sperry slimer
- Breakers, grinders, and rolls with bucking boards, mullers and tube mill.

Drills
- Two Ingersoll-Rand, two Sullivan, one Wood, one Leyner, one Stoper, one Waugh, and one Sullivan. Ingersoll Rand jackhammer, one Hardsocg, one Cleveland, one Fort Wayne Electric, One Scott gas.

Shops
- Pattern shop
- Forge shop
- Foundry
- Machine shop.

E—RESEARCH PERSONAL NOTES

General E4-19 Steel Treating Research Society.

The American Steel Treaters' Society, with headquarters at Chicago, Ill., T. E. Barker, President, and Arthur G. Henry, 154 East Erie St., Chicago, Ill., Secretary, is doing work along the lines outlined in the March, 1919, number of MECHANICAL ENGINEERING. The Chairman of their Research and Standards Committee is Thos. E. J. Janitzky, Illinois Steel Co., South Chicago, Ill.

Lynite Laboratories E1-19

The Lynite Laboratories of the Aluminum Castings Company, under R. E. Carpenter, Manager, are divided into a Research Division under Dr. Z. Jeffries and a Development Division. The Research Division is divided into Sections of Special Research, Metallurgy, Metallography, Chemistry, Physics, and Tests, while

the Development Division is divided into Sections on General Engineering, Automotive Engineering, Permanent-Mold Section, Sand-Casting Section and a Forging Section. The plan of the laboratory is to connect the experimental work with the production work of the country. Address R. E. Carpenter, 2800 Harvard Ave., Cleveland, Ohio.

Marine Engineering E1-19 Use by Private Parties of Naval Experimental Basin.

The Naval Experimental Basin at Washington, D. C., is available for testing models or other devices for private parties provided the expense is borne by the parties and the work does not interfere with Government work. No profit is made, but actual cost to Government is charged. Apply to the Bureau of Construction and Repair, Navy Department, Washington, D. C.

REPORT OF SUB-COMMITTEE ON LUBRICATION

RESEARCH COMMITTEE OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

THE Sub-Committee on Lubrication has recognized certain problems as definitely awaiting solution. Among these problems are those relating to the behavior of lubricants at high pressures and temperatures. The conditions existing in bearings operating under moderate pressures, with therefore relatively thick oil films, are fairly subject to analytical treatment based on the assumption that the viscosity of the lubricant is the sole factor affecting its operation. On the other hand, under conditions of very high pressures or high temperatures or both, it is a common experience that certain organic oils, e. g., lard oil and sperm oil, are much more effective in reducing friction than are mineral oils of similar viscosity, as ordinarily measured. The property or properties causing such differences in lubricating value are at this date more or less obscure. Various terms have been used in recognition of the existence of this lubricating property, such as "oiliness," "greasiness," "unctuosity," "body," etc., but thus far no conclusive experimental evidence has been obtained to show the nature of the physical processes accounting for the observed differences in lubricating value. In discussing this general problem the Committee has recognized the following lines along which investigation might be conducted:

1 *Effect of Pressure Upon Viscosity.* It has long been known that high pressure produces measurable changes in the viscosity of certain fluids. Mr. M. D. Hersey[1] has experimented on this subject, using the ball-and-tube type of viscosimeter described by Prof. A. E. Flowers[2]. Mr. Hersey found that lard oil and (mineral) machine oil, of nearly the same viscosity at atmospheric pressures, showed great increase in viscosity under pressures of 200 to 500 atmospheres. Further experiments in this direction are desirable.

2 *Effect of Temperature on Viscosity.* It is well known that all lubricants decrease in viscosity with increase of temperature, and also that certain organic oils, notably sperm oil, decrease relatively less than the mineral oils. Under very high pressures, such as occur with metal-cutting tools, the temperature of the effective portion of the lubricant may be very high. Viscosity measurements are rarely made at temperatures above 100 deg. cent., but this temperature is probably much lower than that actually reached in severe service: hence, it is desirable to experiment on the viscosities of lubricants up to the temperatures of volatilization or of disintegration.

3 *Adhesion (Capillarity).* Experiments have thus far not shown slipping at the boundary surface between the lubricant and the solid surfaces at moderate rates of shear in the lubricant; but it is still a question whether such slipping may not occur under excessive rates of shear, such as may exist when the film is exceedingly thin. Mr. Albert Kingsbury has experimented with a device consisting of a slightly tapered plug rotating in a ring, the parts being of hardened steel, closely fitted by grinding. The thickness of the oil film between the surfaces was determined by micrometric end adjustment of the plug. With films as thin as 0.000025 in. and rates of shear up to 261,000 radians per sec., at atmospheric pressure and temperature, there was no indication of slip, and no deviation from the ordinary law of viscosity that could not be attributed to inaccuracy of the fitted surfaces. It is possible that some form of experiment might be devised which would extend our knowledge in this direction. If slipping should be shown in any case, there would further arise the question whether it depends on the nature of the bearing metals.

4 *Adsorption.* The suggestion is made that the lubricants that exhibit oiliness in a marked degree may contain solids in solution, which tend to concentrate at the boundary surfaces, thus increasing the viscosity at the surface, and therefore enhancing the lubricating value under conditions of very high pressure. There is at this date no direct evidence on this point, except in the case of the use of soap dissolved in the water used in hydraulic cylinders, the soap being found to concentrate upon the metal surfaces, forming a good lubricating film.[1] It is possible that this may account for the good lubricating properties of the various "cutting mixtures" containing soap and water, used for lubricating metal-cutting tools; and possibly the valuable properties of lard oil and of sperm oil, for examples, may be due to similar phenomena.

REPORT OF SUB-COMMITTEE ON BEARING METALS

RESEARCH COMMITTEE OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

IN THE January number of MECHANICAL ENGINEERING, our Committee made a brief report giving concisely the reason for abandoning our original plan of first publishing a complete compendium of the technical literature on bearing metals. At the time we also pointed out what we considered the most promising outlook for future study and investigation.

It is our conviction that a large amount of valuable time is being wasted in testing bearing alloys, in determining characteristics that are of no consequence and are utterly meaningless. The only mechanical or physical test of a bearing alloy, in the

Tentative report for presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

aggregate, that can serve any useful purpose is that of determining whether the given alloy has a sufficiently high factor of safety against possible distortion or rupture under specified service conditions at service temperature. All other characteristics are of a microscopic nature, depending entirely upon the properties of the individual crystals of the alloy, upon their orientation, relative hardness, fusing temperature, quantitative proportions and the like.

Our studies have convinced us that any work on our subject without the application of modern metallography is an absolute waste of time; we also feel that studying the hardness of the individual microscopic crystals is of the greatest importance in supplementing the application of metallography to our subject.

The instrument shown in our last report has been perfected to a much higher degree and three of them have been substantially completed, one for each member of our Committee. This instrument determines the characteristic of a crystal which is the combination of three of the five fundamental conceptions of hardness[1]; namely, the combined effect of cutting hardness, scratch hardness, and penetration hardness. This is done by very slowly moving an exceedingly hard and sharp point[2] under a definite pressure, over a highly polished surface of the crystal to be tested; in fact, the point is moved so slowly that no additional penetration is effected by stopping. The point is a solid right angle or the corner of a cube, mounted in such a manner that the diagonal of the cube will be normal to the surface tested, and having an edge of the cube advance directly in the line of motion. The motion is effected by a slow micrometer feed. The width of the cut, scratch, or penetration is a function of its depth and, therefore, measuring the width of the mark gives us the means for determining this combined characteristic representing the hardness of any crystal. The instrument is properly called a *Microcharacter*.[3]

In order to lay the broadest foundation for our work, one that will facilitate the coöperation of other investigators and will make all results directly comparable, it is necessary that conventional units be established; that is, that a *Scale of Microhardness* be determined upon. With the establishment of this scale it will be possible to consider the various crystals in the many different alloys in terms of exact degrees of hardness. This is the work that occupies the attention of your Committee at the present time.

Experience well shows that a single homogeneous metal is not suited for bearing purposes, and that the first requirement for a bearing metal is that it be an alloy composed of at least two metals, or a metal and a metalloid, which shall have at least a limited degree of solubility while in the molten state; but that upon cooling it shall partially separate out into dissimilar crystals, and thus form the proper microstructure which is necessary in all bearing alloys. It is not only necessary that a bearing alloy shall be composed of chemically dissimilar crystals, but it is all-important that these crystals shall have a marked degree of difference in their physical hardness and wearing qualities.

The degree of relative solubility necessary for the constituents of bearing alloys is well illustrated by the copper-tin and the copper-zinc compounds, and this also illustrates why bronze is a better bearing alloy than brass. For example, with the addition of not more than 11 per cent of tin to copper, a three-phase alloy is ordinarily produced—less than a two-phase alloy cannot be produced; even with the most instantaneous chilling effect, crystals of different chemical composition are produced. While on the other hand, with 11 per cent of zinc added to copper only a single-phase alloy can be produced, however slowly it may be cooled; that is, all of the crystals in this copper-zinc alloy are of the same chemical composition, and therefore all have the same physical properties. Quite the opposite is true in the copper-tin alloy, an extreme dissimilarity of crystals existing both as to chemical composition and physical hardness. Now, it is due entirely to this dissimilarity of crystals in the bronze that makes it a better bearing alloy than brass.

In the solidifying of the molten bronze the tendency of the tin to separate from the copper is far greater than that of the zinc in the solidifying of brass, for the reason that the bronze solidifies with a distinct microscopic heterogeneity. The matter of having a proper microstructure in a bearing alloy is always of far greater importance than its exact aggregate chemical composition. The value of an exact or definite chemical composition is secondary, in that it can serve only in producing the desired microstructure in a given alloy, provided the alloy is subjected to the proper cooling conditions.

The essential characteristics of all bearing alloys is a structure made up of alternately hard and relatively soft microscopic particles intimately mixed. The function of the hard particles or *bearing crystals* is to support the load and resist the wear. These bearing crystals should not be hard enough to prove distinctly abrasive to the journal surface. General experience shows that an extreme hardness of the bearing crystals is characterized by an excessive wear of the journal. The function of the softer or more readily abraded crystals is that of being plastic and permitting the bearing crystals to adjust themselves to surface requirements of the journal. These softer crystals are also more readily abraded, and therefore wear slightly below the surface of the bearing crystals and thus form slight depressions upon the bearing surface which serve for the retention of the lubricant. However infinitesimal in amount this may seem, nevertheless it is this lubricant that prevents scoring or seizing when the journal is starting up from rest at a time when actual metallic contact between the bearing surfaces exists. The same is equally true under an excessive load. This function of retaining a slight quantity of the lubricant upon the bearing surfaces when metallic contact exists, characterizes a bearing alloy in its truest sense. Therefore a bearing metal may be defined as: *An alloy that is capable of retaining a lubricant on a bearing surface.*

In the operation of a bearing under normal conditions, when a continuous and unbroken film of lubricant exists it matters little what metals are used while the film is sustaining the entire load. In the starting and stopping of the journal, however, or at all such other times when the film is interrupted and metallic contact exists, it then becomes very important that the properties of a bearing metal should be present.

A matter of importance, which seems not to have been considered heretofore, is the fusing temperature of the bearing crystals. From observations made it is evident that under severe conditions where relatively low-fusing bearing crystals exist in a high-fusing alloy these bearing crystals actually fuse on their surfaces during the process of the "running in" of the bearing. The delta copper-tin crystal (Cu_4Sn) may be cited as a particular example, and in some severe conditions corresponding to automotive worm-drive service the alpha copper-phosphorus crystal (Cu_3P) seems to function in a similar manner. It is doubtful whether these conditions ever obtain in any of the babbitts, since their bearing crystals are the highest-fusing compounds of these alloys.

The study of bearing metals is very incomplete unless these alloys are considered in conjunction with the other corresponding bearing member. The extreme variety of modern steels makes this necessary, since a bearing alloy suited for a soft low-carbon machine-steel journal would not be an economic selection for a high-carbon nickel-chrome heat-treated journal, and a proper selection for the latter would prove destructive for the former.

It seems exceedingly improbable that laboratory accelerated service tests can ever give general satisfaction owing to the difficulty of reproducing in a few hours' time the equivalent of many years of service conditions. It is our conviction that much more can be learned from the study of failures, and also in studying old bearings (together with their journals) which have given eminently satisfactory service for an exceptionally long period.

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

SUBJECTS OF THIS MONTH'S ABSTRACTS

AIR MACHINERY

GOVERNOR FOR REGULATING PRESSURE OF GAS EXHAUSTERS AND BOOSTERS. Description of a new device designed to react instantaneously upon slight changes of pressure applied to the governing of rotary exhausters. To comprehend it thoroughly, it is necessary to understand the difference between throttling regulation and cut-off regulation.

In a rotary exhauster working within the limits of intake and discharge pressure the work done by the engine per revolution is constant as long as the elements are constant.

If two engines work side by side, one regulated by a throttling governor and the other by a cut-off governor the indicator cards will be as shown in Fig. 1. In the case of throttling regulation any increase in the speed of the engine will have a given position of the governor result in a greater throttling loss and in less work per revolution. With a cut-off regulation if the engine speeds up the work per revolution remains practically constant and no large force is required to return the speed to normal unless that force comes from the engine governor.

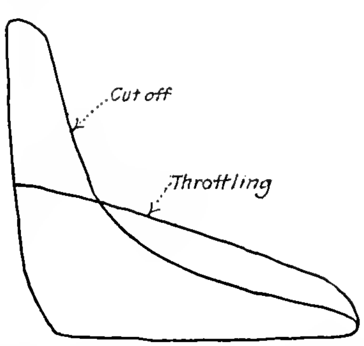

FIG. 1 INDICATOR CARD FOR TWO ENGINES, ONE WITH THROTTLING AND THE OTHER WITH CUT-OFF REGULATION

In gas exhausters, particularly in connection with by-product extraction, the pressure at the exhauster must be kept constant within 5 mm. of water, which means a closeness of regulation of 0.05 per cent, or, roughly, 100 times as much as in compressor practice.

The new governor shown in Fig. 2 is of the float type. It is equipped with a stabilizing chamber which is partly filled with water to prevent it from following the influence of the pressure too far. (Should the float tend to rise under the influence of less vacuum inside of it, the water in the stabilizing chamber is lifted so that the float becomes heavier and resists being carried too far.) To enable the float to find its correct position the stabilizing chamber is purposely made leaky, the extent of the leak being determined by an adjustable valve, of which the screw is shown at 3. With the valve wide open the governor surges; with the valve dead shut it does not maintain a constant pressure.

The motion of the float is communicated to a vertical pilot valve 1 by means of light rods with very small pin joints which approach frictionless knife edges in their action. The pilot valve is equipped with a compensating return mechanism provided to prevent slight displacements of the valve from moving the valve gear of the engine continuously away from the starting position

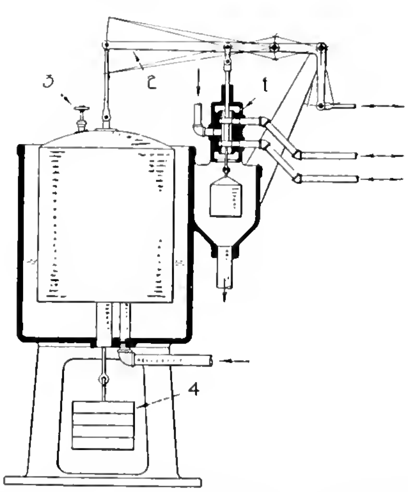

FIG. 2 SECTION OF THE ROOTS PRESSURE GOVERNOR FOR GAS EXHAUSTERS

until the resulting speed change and pressure change move the governor and displace the pilot valve in the opposite direction.

The lever 2 is so connected with the valve gear that motion of the latter induced by opening of the pilot valve closes it.

It has been found by experiment that with releasing gear for Corliss or poppet valves 3 mm. total fluctuation of suction pressure can be obtained, except during periods of excessively quick changes in the various pressures and gas volume when the pressure fluctuation will reach 10 to 15 mm. of water. BUREAU OF STANDARDS

New Instruments for Measuring Combustible Gas in Air

NEW FORMS OF INSTRUMENTS FOR SHOWING THE PRESENCE AND AMOUNT OF COMBUSTIBLE GAS IN THE AIR, E. R. Weaver and E. E. Weibel. A study has been made of the combustion of small amounts of gas in the air at the surface of electrically heated wires and the application of this phenomenon to the design of instruments for the purpose of detecting the presence

and indicating the amount of combustible gas in the air. As a result of this study three types of instruments, each especially adapted to certain uses, have been designed, tested and found to work satisfactorily.

The action of one of these instruments depends upon a resistance change, one upon a heating effect upon an adjacent bimetallic strip, and one upon the light emitted from the heated wire.

A discussion of the principles involved in the design of the instruments and specifications for their construction are given. (Abstract from Scientific Paper No. 334)

Solar Radiation as It Affects Balloons

EFFECT OF SOLAR RADIATION UPON BALLOONS, J. W. Edwards and M. B. Long. This paper describes briefly the effect of solar radiation upon balloons and includes experimental measurements on typical balloon fabrics.

Preliminary to the subject proper a summary is given of the characteristics of solar radiation and atmospheric conditions which have a direct relation to the problem. The radiation characteristics of the fabrics themselves are discussed. A series of measurements on representative balloon fabrics showed an absorbing power for solar radiation varying from 45 to 90 per cent.

The fundamental relations governing the temperature of balloon fabrics when exposed to solar radiation are outlined and the application of these to the calculation of balloon temperature is discussed. The multiplicity of factors involved makes the calculation of such temperatures of very limited value, but by means of measurements on a model balloon the magnitude and distribution of the temperature involved, in both gas and fabric, are well illustrated. The temperature of the upper surface of the model balloon in bright sunlight under certain definite conditions, varied from 20 deg. cent. to 39 deg. cent.

The importance of the radiation characteristics of fabrics in governing buoyancy changes, in causing increased permeability of the fabric to hydrogen and in its effect on the life of the fabric is emphasized as a factor in the selection of fabrics for various purposes. Other factors affecting the selection of fabrics are summarized and their relation to the radiation characteristics is pointed out. (Abstract from Technologic Paper No. 128)

Methods of Testing and Specifications for Soaps

SPECIFICATIONS FOR AND METHODS OF TESTING SOAPS. This circular includes a general discussion of the composition of soap and the varieties of toilet, laundry, scouring and soft soaps for which specifications are proposed. These specifications cover milled toilet soap, white floating soap, liquid soap, shaving soap, salt-water soap, special-grade laundry soap, ordinary-grade laundry soap, chip soap, soap powder, hand grit soap, scouring soap (A), scouring soap (B), and automobile soap. The methods described include those for sampling deliveries, for preparation of the laboratory sample and for the following tests and determinations: Matter volatile at 105 deg. cent.; free alkali or acid; alkali as alkaline salts; silicate; sulphate; matter insoluble in water (insoluble siliceous material); unsaponified saponifiable matter; preparation of total fatty acids; titer test; acid number of fatty acids; total alkali; chloride; rosin; total anhydrous soap; sugar (qualitative test); feldspar and quartz; potash and soda. (Abstract from Circular No. 62, 2nd edition).

ENGINEERING MATERIALS (See also Heat-Treating)

EFFECTS OF PHOSPHORUS ON MALLEABLE CAST IRON, J. H. Teng. Discussion based on experiments conducted at the University of Birmingham. Two series of test bars were prepared; one by adding phosphoric iron to a pure American wash white iron, and the other by adding the same to iron supplied by malleable-iron founders in Birmingham.

Tensile transverse and bending tests were made and Figs. 3 and 4 show the relation between transverse strength, deflection and the proportion of phosphorus in both types of irons.

In the tensile-strength tests it was generally found that the maximum stress elongation and reduction of area are gradually lowered with increasing phosphorus, while the yield point is gradually raised.

The bars belonging to the pure-iron series show a higher yield point but a lower maximum stress, a lower elongation and a smaller reduction of area than those belonging to the common-iron series, which may, however, be due to the higher silicon content in the former.

The following general conclusions were reached:

The addition of phosphorus does not result in any improvement in the mechanical properties of the malleable casting.

Any addition of phosphorus leads to a deterioration in the mechanical properties, as shown by tenacity, elongation, and toughness.

The ill effects of phosphorus do not become marked until about 0.2 per cent of phosphorus has been reached, and this

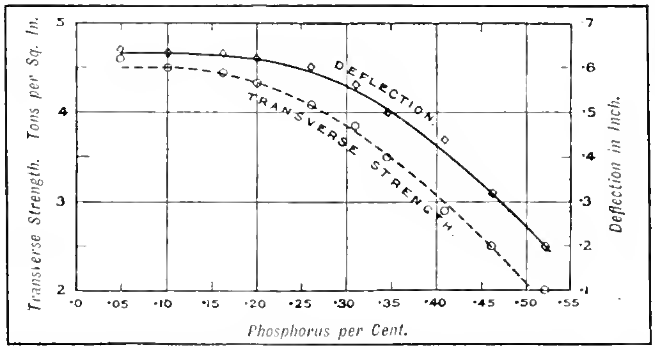

FIG. 3 CURVES SHOWING THE RELATION BETWEEN TRANSVERSE-STRENGTH DEFLECTION AND THE PROPORTION OF PHOSPHORUS IN THE PURE-IRON SERIES

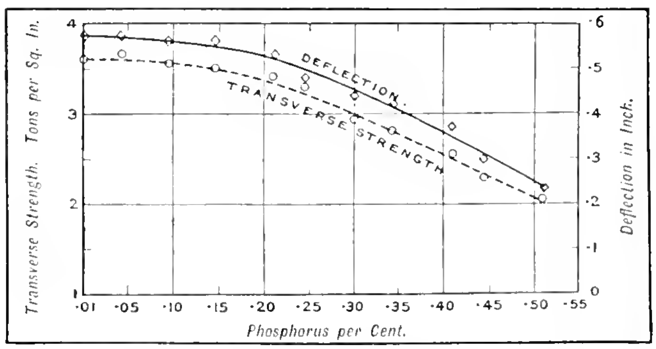

FIG. 4 CURVES SHOWING THE RELATION BETWEEN TRANSVERSE-STRENGTH DEFLECTION AND THE PROPORTION OF PHOSPHORUS IN THE COMMON-IRON SERIES

may be considered to be the approximate limit for commercial purposes.

The presence of a considerable amount of silicon and manganese is of more importance than the absence of sulphur with regard to the success of the annealing operation.

The origin of the sulphide of iron in the spent oxide is attributable to the presence of sulphur compounds in the reducing atmosphere in the furnace near 900 deg. cent. (Paper before British Iron and Steel Institute, reported through *Foundry*, vol. 47, no. 320, April 1, 1919, pp. 151-156, 9 figs., *e*)

HEAT-TREATING

Dilatometer Method of Investigating Heat-Treating of Carbon Steel

MECHANISM OF TEMPERING CARBON STEEL, Pierre Chavenard. An extensive discussion based on experimental research and abstracted from a recent issue of *Revue de Metallurgie*.

In order to observe in all details the transformation of steel during tempering and in order to connect in a quantitative manner the intensity of observed phenomena with other experimental conditions, it is necessary to have at every instant and in all points of the test piece under investigation the same temperature and hence the same rate of cooling.

For purposes of investigation little value must be placed on methods of thermal analysis, as their sensitiveness is proportional to the mass of the test piece and nearly independent of its shape. To this class belong all methods based on the study of temperature-time curves, variation of magnetic properties, etc. If, with these methods, very small pieces are used for purposes of investigation, certain details may remain unnoticed through lack of sensitiveness of the process employed. On the other hand, if large pieces of steel are used, there is a danger of the presence of excessively different conditions in various parts of the test piece.

Because of hysteresis phenomena, the use of electrical reactions for discovering changes of state of steel leads to considerable experimental difficulties.

The "dilatometer" method avoids all these pitfalls. The measurement of dilatation of a test piece refers only to one of its dimensions, and that is why in experiments made with a very fine wire it is sufficient to secure uniformity of temperature and rate of cooling in reference to its length. Moreover, the wire may be comparatively short (only a few centimeters long), because the transformation is accompanied by an important irregularity of dilatation, which it is easy to amplify materially by optical means. Furthermore, it is easy to secure uniformity of conditions of cooling, and finally the examination of the wire treated will, in the great majority of cases, enable one to verify in how far this uniformity has been actually secured.

The sensitiveness of this method is not only very high but it is practically independent both of temperature and velocity of reaction. This extremely important property makes it possible to disclose at low temperatures the most feeble manifestations of change of state from γ to α. Finally, the phenomena of dilatation are accompanied by the exercise of considerable forces with respect to which the inertia of the amplifying apparatus is quite negligible. Because of this, the readings of the dilatometer translate faithfully and without lag the maximum of transformation, no matter how great may be the velocity of cooling.

Of course, to cool a wire a few hundredths of a millimeter in diameter, immersion into a liquid was out of question, but the spontaneous cooling in an inert gas of a steel wire previously brought to red heat by an electric current may be rapid enough to produce tempering. In fact, according to a deduction from Newton's law, the velocity of cooling varies in inverse proportion to the diameter of the wire, and for a wire of small section attains a high value. In order to vary in a continuous manner the rate of cooling, resort is made to an experimental process based on the high heat conductivity of hydrogen. All other conditions being equal, the fall of temperature in hydrogen is about three times what it is in nitrogen, and mixtures of these two gases in various proportions provide a means of carrying out on the same test piece a series of temperings at various predetermined rates of cooling.

The extremely low mass of this test-piece wire appears to be an obstacle in the way of directly measuring the temperature during cooling, but this difficulty is circumvented by the use of a comparison wire made of "baros," a metal whose heat properties are very close to those of steel in the γ state. The two wires heated to the same temperature and then at the same time permitted to cool, will, with proper precautions, maintain the same temperature up to the beginning of transformation from γ to α. In the arrangement used by the author the expansion of a sample of baros measures its temperature and indirectly determines also the temperature of the steel sample.

The comparison wire permits also to employ the dilatometric method under a differential form, which gives it an extremely high sensitiveness. The apparatus based on that principle automatically draws a curve whose abscissæ represent the expansion of the sample and the ordinates the difference in the expansions of the two samples. This curve is recorded on a photographic plate, while the periodic interruption of the luminous ray marks the time in conformance with the principle previously employed by Le Chatelier. This makes it easy to compute the velocity of cooling at any point in the photographic diagram.

A question may be raised as to how far the conclusions drawn from a study of extremely fine wires may be applied to the case of commercial tempering of pieces having a considerable mass.

There is no doubt that fundamentally the phenomena must remain qualitatively the same notwithstanding the changes in the dimensions of the piece treated. On the other hand, however, it is certain that the magnitudes of the necessary rates of cooling for tempering are dependent on these dimensions. In fact, during rapid cooling of a large piece the central zones are subjected to a high pressure due to the contraction of the layers lying on the periphery and first reaching a low temperature. This pressure tends to oppose transformation from γ to α, which takes place with increase in volume.

In other words, the physical variables which determine for each element of volume of steel the occurrence of transformation

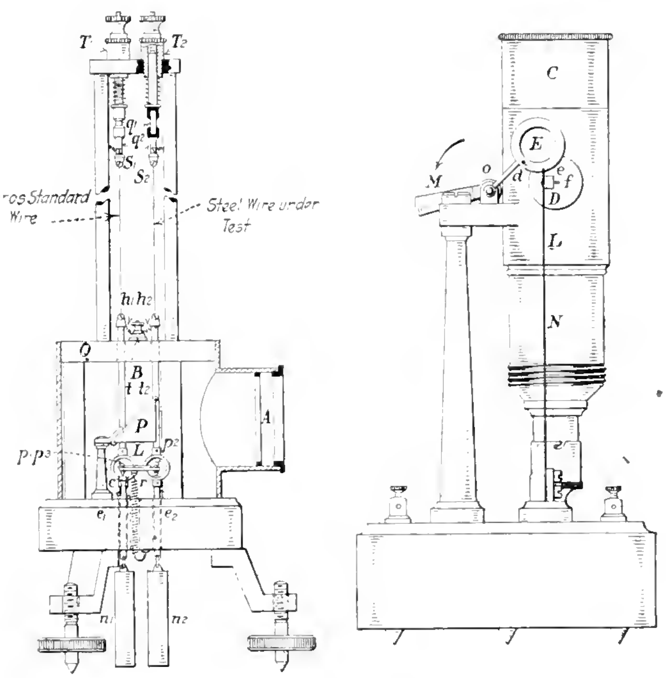

Fig. 5 Chavenard Differential Dilatometer

are temperature, pressure and their variations as a function of time.

In the present investigation the author leaves the action of pressure practically out of consideration. The rates of tempering measured by the method employed here are really the upper limits, but their determination is nevertheless of great interest because it enables one to classify different kinds of steel in accordance with their aptitude for tempering.

The whole article is too extensive for abstracting and because of this only the conclusions are reported here, in addition to which is given a description of the differential dilatometer employed in the present investigation.

The following conclusions are reached by the author:

In most reversible steels, such as the carbon self-hardening steels, the tempering occurs always in accordance with the same mechanism, even though the velocities of reaction necessary to obtain comparable states may be in two different cases extremely different from each other.

When the transformation in cooling takes place entirely at a high temperature, say, 600 to 700 deg. cent. (Ar′), it leaves the metal in a state of physicochemical equilibrium, state of anneal. In accordance with the rapidity of the change of state the steel may consist of pearlite or troostite.

The tempering takes place because of the fact that at low

temperatures (150 to 300 deg. cent.) there is a transformation from γ to α of the austenite. Its intensity is the greater in proportion as this transformation Ar'' is nearer to completion; when the tempering has been completed entirely the steel consists practically exclusively of martensite.

Between the two extremes of treatment, anneal and full temper, there may be had a series of semi-tempers due to the superposition in each elementary volume of steel (the linear dimensions of which are of the order of 0.01 mm.) of the transformation of anneal (Ar') and of temper (Ar''); the semi-tempered steels consist of troostite and martensite, or of ferrite and martensite.

The beginning of tempering is always clearly defined, while the disappearance of Ar', that is, the completion of the tempering, is a limited phenomenon, which sometimes proceeds quite slowly. If the energy of the treatment be carried out to exaggeration, the increase in the proportion of austenite is maintained in the steel and the efficiency of tempering is decreased.

Either by studying tempering on wires or by determining the magnitude of anomalous occurrence of cementite in treated steels, exact indications may be secured as to the nature of the constituents of tempering and annealing. Martensite, which is due to the transformation of austenite at low temperature, appears to be an unstable solid solution of carbon in α iron. Troostite in negative tempers, or half-tempers, osmondite and sorbite in anneal must be considered as aggregations of iron and cementite.

In order to obtain a steel of the same strength of temper recourse must be had to cooling, which must be the more rapid the less the heating was carried beyond the Ac state. If it be desired to obtain tempers of approximately equal strengths in different steels heated to the same initial temperature, the velocity of cooling which must be employed must increase in proportion to the decrease in carbon content. The experiments described in this paper have, it appears, for the first time led to a quantitative expression of these relations for the most simple cases, namely, infinitely small strength of temper and samples of negligible mass.

The ability of a steel to take temper may be defined quite precisely by the temperature of heating, the initial velocity and the limit curve of anneal. The determination of this curve is of essential theoretical and practical importance. Hitherto it could be obtained exactly only with self-hardening steels and the investigation of very reversible steels has been carried out to a much smaller extent because of the lack of a convenient and exact process for the determination of very high velocities of cooling.

The method of thermal analysis based on automatic record, of the dilatation of a steel wire during its cooling in an inert atmosphere appears to fill this need and the availability of an exact and convenient method for measuring the degree of irreversibility of steels opens a field for new investigations, one of the most important of which will have to do with the specific action of traces of elements which ordinary steels contain as impurities, or of special alloying elements which may enter into their composition.

Differential Dilatometer. In the dilatometer, Fig. 5, the steel wire as well as the standard wire having a diameter of 0.23 mm. are attached on the top to invar holding screws S_1 and S_2, which are in one piece with the suspension heads P_1 and P_2. These wires are held by invar rods t_1 and t_2 to the weights W_1, W_2, which give to the wires a tension of 0.5 kg. per sq. mm. (711.16 lb. per sq. in.). The suspension heads are so arranged as to permit an adjustment of the position of the wire, namely, the twist about its axis and a slow upward movement.

The dilatations of the wires are transmitted to the optical lever L, the purpose of which is to amplify them. This lever, provided with a flat mirror M, is carried on three tempered chrome-steel pin points p_1, p_2, p_3, arranged in a right-angled triangle. The dilatation of the wire gives to the optical lever a complex movement equivalent to two rotations: one about an axis OX, this rotation being proportional to the difference of the elongation of the two wires; and another around axis OY, proportional to the elongation of the standard wire. The curves traced by the ray reflected from the mirror enable reading the indications of the apparatus.

In order to compute the velocity of cooling the luminous ray is eclipsed periodically so that the photographic curve consists of a succession of interrupted lines, each of which has been drawn within the same time interval.

The original article describes in detail the method of using the differential dilatometer and the results obtained therewith. (Mechanisme de la trempe des aciers au carbone, Pierre Chavenard, *Revue de Metallurgie*, vol. 16, no. 1, January-February 1919, pp. 17 to 79, 17 figs., *etA*)

Troubles in Case-Hardening and Their Elimination

The Application of Heat in Case-Hardening, Theo. G. Selleck. The practical case-hardener has four important factors to consider: (1) the nature and quality of the material to be treated [laboratory reports of analyses or specifications from manufacturer], (2) temperature at which the material is treated, (3) the carbonizing agent, and (4) time.

The writer considers especially temperature and its uniform application, but points out that the nature and quality of the material to be treated are a prolific source of trouble for the case-hardener.

Steel is not always what it seems to be or what specifications and analyses show it to be. Chemical analysis of steel does not take into account mill faults which may be hidden in various segregations of elements nor does it always find variations of carbon beyond the limits of specifications which are not unusual.

The original article illustrates by photomicrographs cases of segregation which occurred in a steel plate supposed to carry 0.10 to 0.15 per cent carbon. The plate was carbonized and hardened, after which it proved to be very brittle.

Not only upon fracturing the plate did there appear to be no soft center, but in the center of the cross-section of the plate there were numerous little cracks expanding perpendicularly in the direction of the surface of the plate but not quite reaching it. Such conditions cannot be anticipated or determined in advance and often cause heavy loss of material and labor.

The cause of another mill fault frequently discussed in treating plates is that commonly known as lamination due to ferrite ghosts. The remarkable part of this fault lies in the fact that it occurs almost on the weld line or the line between the carbonized area and the soft center.

In addition to such segregations as have been referred to above and which are due to the previous history of the carbonized pieces, there are other segregations called by the writer "segregations of heat" for which the case-hardener is entirely to blame if they occur.

Heat is the primary element of all case-hardening. As iron must be in the gamma state before it can dissolve carbon, heat must be applied in such a manner as to establish this essential condition of the iron.

After pointing out the importance of having a uniform degree of heat throughout the process of carbonizing, the author states that he discovered that by close observation the operator may know almost to a certainty, practically from the beginning of a case-hardening heat, what the final results will be.

It is further claimed that for this purpose no special equipment is needed but only a fair knowledge of heat colors and a proper familarity with the fundamental principles of the case-hardening process. The method developed is based on optical observations made by the writer, which consisted merely of keeping a close watch on the boxes from the time they were put into the furnace cold until they were thoroughly heated or until the color of the boxes blended into the color of the heating chamber of the furnace and noting the manner in which the heat colors displayed themselves over the boxes. From the results of these observations it is claimed that the first show of heat color displayed upon a case-hardening box will indicate without fail the regularity or irregularity of the results of the operation.

In presenting his paper before the American Steel Treaters' Society the author used colored plates which are reproduced in

single color in the paper from which this abstract is made. This limits the ability of describing the color observations of the writer.

In this connection even the original article does not help very much because all illustrations therein are made in black prints. The original paper presented before the American Steel Treaters Society was accompanied by colored plates.

From what he says, it appears, however, that irregularities in coloring of the boxes may be taken as portents of irregularities and results of carbonization, and contrasts of colors tell a story of variations both of penetration and of carbon content which is not told either by physical or chemical tests.

The writer claims that this new method of observation in case-hardening, namely, by colors, opens up a new field for investigation. One of the factors which may be cleared up by such an investigation is the occurrence of inequalities of penetration due to unequal temperatures. Variations of carbon content, however, also affect the amount of penetration. Indeed, it is claimed that in the tests made by the author facts were observed which give a strong impression of possibilities of great variations of carbon existing in the test pieces.

Further, the author emphasizes the fact that the heat diffusion in case-hardening operations does not take place at a uniform rate, because of the different conductivities of the materials through which the heat has to flow. Because of this it is highly desirable to avoid all possible obstacles to uniform diffusion of heat and for the material to be treated as near as practicable to the point of heat generation, which means preheating the case-hardening boxes.

The author secured an even and uniform pentration of carbon content throughout on a batch of several hundred bars of mild steel 8 ft. long. The closed muffle type of furnace was used and 20 bars were handled in each operation, the weight of each charge being more than 950 lb. These bars were placed in the muffle already heated to 1500 deg. fahr. and were held in position until they were uniformly heated to about 1250 deg. fahr. The compound was then introduced and the holding devices removed. The temperature dropped about 200 deg. but rapidly regained an equilibrium between the steel and the compound and in two and one-half hours was at the carbonizing point.

For this purpose the closed-muffle furnace is necessary, but boxes may be used with only slight changes. By a closed-muffle furnace the author means one which can be closed and sealed airtight and so constructed that it may be evenly heated all over. Since the muffle is sealed airtight there is no necessity for covers on the boxes. When the operation of preheating is completed the boxes are removed, covers placed on them if desired, and they are handled just as in the old method. (*Journal of the American Steel Treaters' Society*, vol. 1, no. 3, December, 1918, pp. 87-89, 11 figs., *ptA*)

Advantages of Slow Cooling in Annealing Bronze Castings

HEAT-TREATING BRONZE CASTINGS, G. F. Comstock. Discussion of the effects of annealing bronze-alloy castings and data of experiments made by the author.

The writer describes an experiment in which six tensile-test bars were cast from the same crucible in the same manner. One bar was tested as cast without heat treatment and three bars were heated slowly in an electric muffle furnace to 700 deg. cent. and held there for 30 min. Then one bar was quenched in water, one was taken out and allowed to cool in the air and one was left to cool in the furnace.

This made four bars. The fifth bar was heated to 800 deg. cent. held in the furnace for 30 min. and cooled slowly in the furnace to 600 deg. cent. Then the remaining bar was put in and its temperature maintained at 600 deg. cent. for 30 min., after which both of these bars were allowed to cool slowly in the furnace.

The bars were then tested for yield point, tensile strength, elongation, reduction of area, and hardness, and the results obtained appear to show that annealing at about 700 deg. cent. benefits the alloy, while quenching in water spoils it. (The metal contained 88.5 per cent copper, 9.5 per cent tin and 2 per cent zinc.) In general, however, heat-treated bars show practically no change in yield point or hardness as compared with the untreated bar, while the other properties, especially elongation, were decidedly improved by annealing. (This result is, however, made somewhat doubtful by the fact that the untreated bar had a small flaw.)

An attempt was made to explain by the use of a microscope the failure of the bar quenched in water which proved to be extremely weak in every test, but its structure appeared to be no different from that of the other bars. It seems likely, therefore, that this alloy simply cannot stand the strains produced by sudden cooling in water from a red heat, which makes impractical the idea of trying a double heat treatment consisting of quenching and tempering on copper-tin alloys.

TABLE I PHYSICAL TESTS OF BARS WITH AND WITHOUT HEAT-TREATMENT

Bar heated to (deg. cent.)	Cooled in	Yield point, lb. per sq. in.	Tensile strength lb. per sq. in.	Elongation, per cent	Reduction of area, per cent	Hardness Number	Remarks
Not heated	....	22,100	43,400	26 5	23.7	67	(*a*)
700	Water	18,200	18,700	7 5	6 7	66	(*b*)
700	Air	21,600	44,600	41 5	33 5	67	.....
700	Furnace	20,700	45,400	41.5	34.3	68	.....
600	Furnace	21,800	48,500	50.5	46.2	71	.....
800	Furnace	21,000	48,200	58 0	38 0	67	.....

(*a*) Small flaw. (*b*) Unsound.

The tests also show that the gun metal or 88-10-2 bronze castings can be improved in strength and especially in ductility by annealing at a red heat or 600 to 800 deg. cent. for at least 30 min., followed by slow cooling. The structural change produced is the removal of the dendrites or soft cores and of the eutectoid or delta constituent resulting in a homogeneous polygonal structure. The same change can be produced by annealing any of the ordinary copper-tin alloys.

As to bronze casting in a chill mold, it is said that it solidifies with great rapidity but the liquid metal heats the chill so much that the rate of cooling below 500 deg. cent. is never fast enough to prevent the better constituent from breaking down into the eutectoid. In other words, the chill prevents the development of great differences in composition between the low-tin dendrites and the high-tin ground mass of the alloy.

Very little is said to be known as to the possibilities for heat-treating of manganese-bronze castings and the writer has therefore made a few experiments along this line.

The effect of quenching manganese bronze in water from a red heat is to fill the metal with invisible cracks which ruin the tensile properties of the alloy. If the best elongation is desired, manganese-bronze castings should cool slowly in their molds and should not be shaken out of the sand hot, unless stiffness is desired rather than ductility.

Interesting data are also presented on the subject of heat treatment of aluminum bronze. (*The Foundry*, vol. 47, no. 321, April 15, 1919, pp. 189-194, 18 figs., *dp*)

HYDRAULIC ENGINEERING

Swiss and French Devices for Automatically Limiting Output of Pressure Piping

AUTOMATIC APPARATUS FOR REGULATING THE OUTPUT OF PRESSURE PIPING, Prof. W. De Schoulepnikow. Pressure piping which connects the starting chambers in hydroelectric plants is often subject to extremely high pressure and to water hammer, which increases the pressure still more. Rupture of such piping is by no means rare and may have grave consequences, as in such cases both the starting chamber and the supply channel

may be emptied and the plant located below runs great danger of being swamped and destroyed. It is therefore absolutely necessary to provide some means to stop the flow in case of rupture of piping.

The simplest method is to put a watchman on the starting chamber and make him responsible for closing the inlet sluice on the piping as soon as an accident becomes in evidence. This method, however, is expensive and not convenient as it is impossible to rely on the constant attention of a watchman.

A better solution is to operate the sluice by means of electric motors receiving their current from the plant. This method, however, likewise requires a certain amount of attention on the part of the plant personnel.

Because of this it appears to be a better plan to employ apparatus which will automatically stop the flow in the piping as soon as it has exceeded a certain amount fixed in advance. Such apparatus may be made to operate either hydraulically or mechanically. Bouchayer and Viallet, engineers in Grenoble, France, have invented a siphoning automatic apparatus which has been employed in the installation at Soulom and the sketch shown in Fig. 7 has been given to the author by the inventors.

The pressure piping $A\ B\ C$ has the form of a siphon in which the point B is above the maximum level h-h of the reservoir. The pipe AI equipped with the sluice K connects the two branches of the siphon and serves to fill up the pressure piping. This latter is also equipped with a snuffle valve E connected to the peak of the siphon by the pipe G. The priming in the Soulom plant is effected by means of a special water jet, which, at a given moment, aspirates the air from the siphon. The pressure piping is then ready to function.

According to the Bernoulli law, when water flows through the pipe the level in the snuffle valve E sinks as the flow of water in the conduit increases. If it goes below the point F, air enters, the siphon is deprived of its priming and the flow of water is stopped at once. Because of this, all that is necessary is to determine the height H in such a manner as to produce this loss of priming when the velocity has attained a dangerous magnitude, such as would happen, for example, in case of a rupture of the conduit.

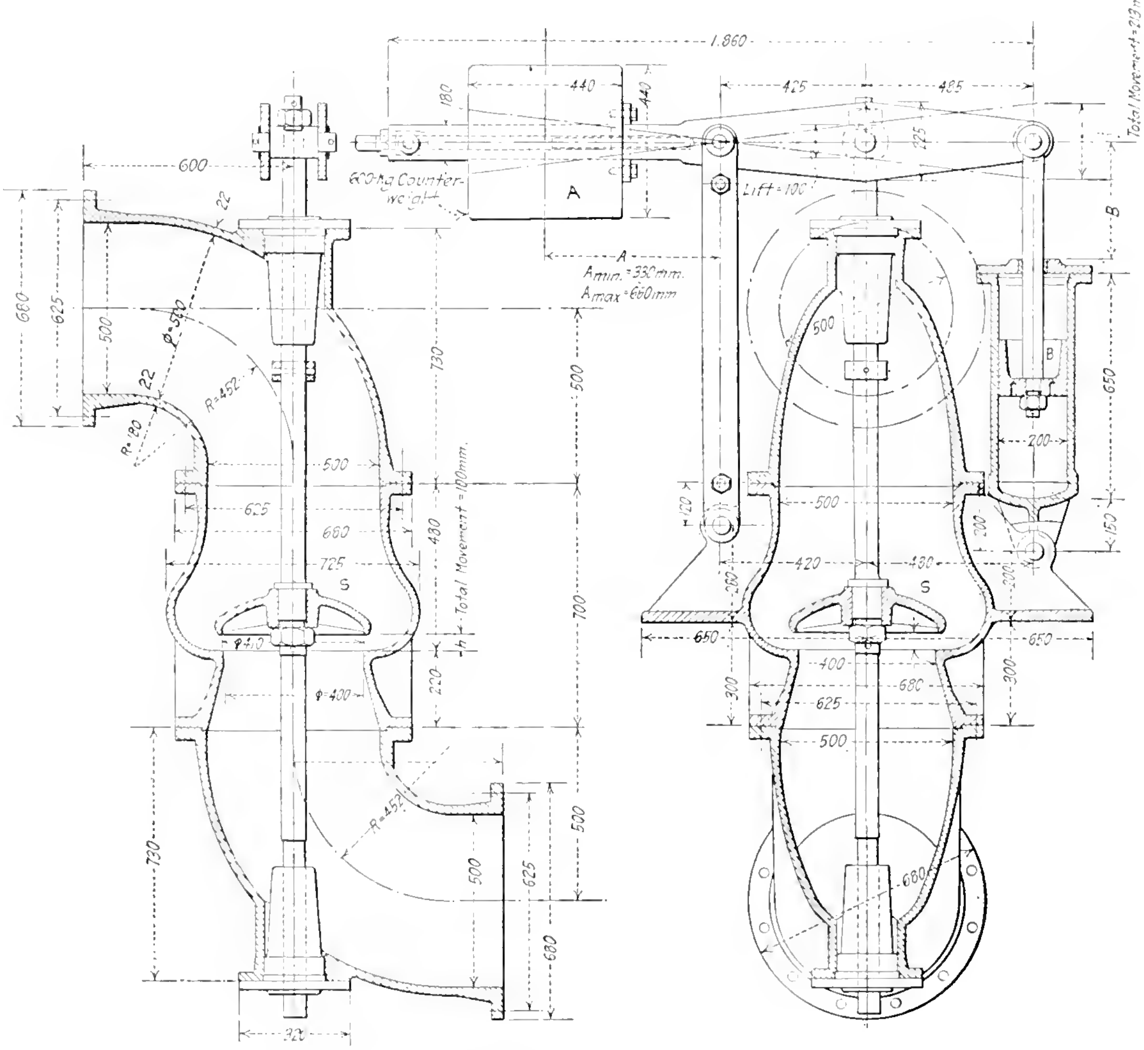

Fig. 6 Automatic Valve-Closing Device in the Pipe at the Fully Plant, Switzerland

This apparatus requires, however, that the level of water in the starting chamber should not vary too much.

Apparatus in which the stoppage of flow is effected mechanically are free from this rather inconvenient condition, but require a certain amount of attention to maintenance. There are several types of them.

As an example, in Fig. 6 is shown a gate located at the origin of the pressure piping in the Fully plant, which uses the highest head in the world, namely, 1650 m. It is easy to see that the rupture of a pipe working at that pressure would produce a tremendous amount of damage.

The automatic apparatus comprises a valve S balanced by an adjustable counterweight A which keeps the valve open as long as the velocity of water does not exceed a given value. If this value is exceeded the pressure of the water tends to force the valve against its seat. The hydraulic brake B protects the valve against an excessively sudden closure which might break it. Table 2 and Fig. 8 indicate the output for the different values of

the valve lift h, as well as the position which the counterweight has to occupy for each of these values.

It is believed that this is the first publication of these data ever made. (*Bulletin Technique de la Suisse Romande*, 45 anneé, no. 7, April 5, 1919, pp. 57-58)

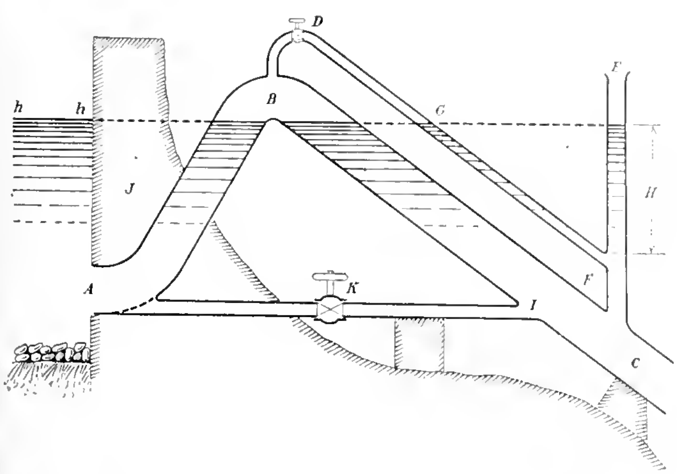

Fig. 7 Automatic Flow Arrester for Pressure Piping in Hydroelectric Plants

INTERNAL-COMBUSTION ENGINEERING

Atmospheric Humidity as It Affects the Output of Internal-Combustion Engines

Atmospheric Humidity and the Testing of Internal-Combustion Engines, Capt. Ch. Boileau. The writer discusses the question whether atmospheric humidity really affects the output of internal-combustion engines, and if so, how the proper correction shall be made. In the precision testing of engines it is usual to reduce the engine power to a pressure of 760 mm. by multiplying the value actually obtained at a pressure H by $760/H$. Calculation and experiment likewise prove the correctness of this so-called barometric correction.

The second correction (that for temperature) which is always applied in testing gas engines is not as a rule resorted to in testing explosion-type engines with heat-jacketed carburetors. However, with carburetors having no heat jacket such a correction may be necessary, as will be shown later on.

In central and western Europe the atmospheric pressure may easily vary 5 per cent either way, which indicates the amount of error which would be committed if a proper correction were not applied. But there is a third source of error, which, as a rule, is not taken into consideration and the importance of which is equally great. This is the humidity of the atmospheric air. In the present article an attempt is made to show the theoretical basis for such a correction and, as far as possible, evaluate the influence of this factor. An objection may be made to the effect that at the instant of the explosion, phenomena of dissociation occur which it is impossible to measure. This is true; and in the present instance only comparative results may be considered on the assumption that no dissociation occurs.

As regards the method employed in the present instance, it is claimed that it is nothing but a simple application of the usual thermodynamic formulæ—the Zeuner tables for water vapor and the Sorel tables for gasoline vapor. The specific heat at constant volume for superheated water vapor was taken to be 0.55:

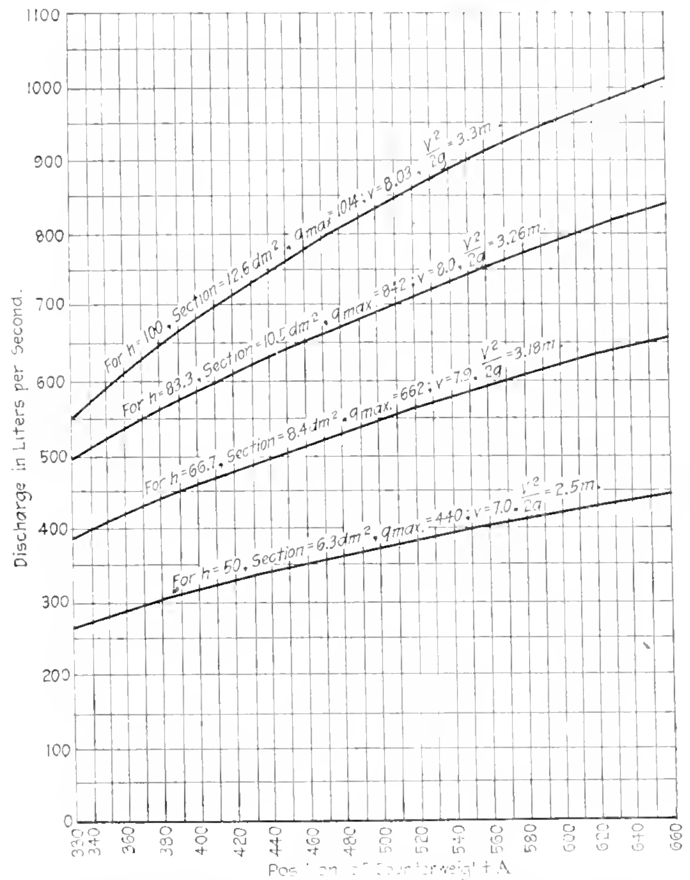

Fig. 8 Diagram of Flow as a Function of the Position of Counterweight in the Apparatus Shown in Fig. 6

1.3 = 0.42 at high temperatures and 0.39 at low temperatures during the period of compression, in calories per kilogram. The following calculation is presented. A swept cylinder volume of 1 cu. m. is assumed with a coefficient of volumetric compression of 4.7, and at first constant atmospheric pressure and temperature (760 mm. and 15 deg. cent.), the only variable being the humidity of the air. Furthermore, since the e ternal pressure does not vary, the same calculations are repeated for different constant temperatures such as 0 deg., 30 deg. cent., etc. Finally, a third variable is introduced, atmospheric pressure, to determine whether its influence is properly taken care of by means of the correction factor $760/H$ when both temperature and hygrometric tension are taken into consideration together.

Constant Atmospheric Pressure

In this connection two cases are considered under the general assumption that the atmospheric pressure is 760 mm. and that the air is first absolutely dry at 15 deg. cent. and next absolutely humid (i.e., saturated) at 30 deg.

Case 1. $H = 760$, $t = 15$ deg. cent., $f = 0$. The tension of the gasoline at the saturation point and at 15 deg. cent. is equal to 0.304 kg. per sq. mm. The density of gasoline vapor is taken as 3, with air as unity. Hence, in order to saturate 1 cu. m. at that temperature, it is necessary to have

$$1.293 \times 3 \times \frac{0.304}{1.033} \times \frac{273}{288} = 1.083 \text{ kg.}$$

The tension of the gasoline vapor will be given if we assume that the carburetor has an exhaust regulation at 1/20 and is expressed by the equation

$$1.293 \times \frac{273}{288}\left(1 - \frac{x}{1.033}\right) = 20 \times \frac{1.083}{0.304} x$$

whence

$$x = 0.017 \text{ kg. per sq. cm.}$$

and the weight of the air is then

$$1.293 \times \frac{1.033 - x}{1.033} \times \frac{273}{288} = 1.203 \text{ kg.}$$

and hence the weight of the gasoline is 60.15 grams.

Compression. For the mixture $pv^{1.41} =$ Constant, and hence $p = 7.75$ kg. per sq. cm., and $t = 187$ deg. cent.

Explosion. The amount of heat produced by explosion is 661.65 cal. The air necessary is $15.1 \times 0.06015 = 0.908$ kg. and the excess air is therefore 0.295 kg., hence

$$661.65 = (T - 460)\ \{[0.06015\ (3.091 \times 155 + 11.62 \times 0.174) + 0.295 \times 0.17] + 0.42 \times 0.0849\}$$

from which

$$\tau = 3293, \text{ and pressure} = 55.43 \text{ kg. per sq. cm.}$$

The work of one cycle is equal to the difference between the work of expansion and the work of compression, where both are evaluated by the formula

$$\tau = \frac{\gamma - 1}{p_1 v}\left(1 - \frac{1}{\left(\frac{p_1}{p_2}\right)^{\frac{\gamma - 1}{\gamma}}}\right)$$

whence

$$\tau = 58.6v$$

The author uses conventionally 58.6 to express the value of this factor.

Case 2. $H = 760$, $t = 30$ deg. cent., $f = 100$ per cent, $F = 0.043$ kg. per sq. cm. The tension of gasoline at saturation equals 0.403 kg. per sq. cm.; the weight of the water equals 30.15 grams, the weight of air equals 1.115 kg.

Gasoline to the amount of 55.75 grams is injected and the whole brought to 760 mm. pressure and 15 deg. cent. temperature by means of the heat jacket. Calculation shows that 1 cu. m. of the mixture contains

1.190 kg. of air
0.0596 kg. of gasoline
0.0128 kg. of water vapor and
0.0194 kg. of entrained condensed water.

Compression. First the writer considers the behavior of a cubic meter of dry steam. If it be treated as superheated steam, a final pressure of 0.132 kg. and a temperature of 202 deg. cent. are obtained.

Under the assumption that 19.4 grams of water are gradually evaporated with the change in compression, it is found that the final state will be the same as if this amount of water were injected into the volume of superheated steam maintained at 0.132 kg. pressure and 202 deg. cent. temperature. This final state is computed from the ordinary equation of mixtures, bearing in mind that if x grams have been evaporated then $(12.8 + x)$ grams of vapor saturate exactly 212.8 liters at that temperature.

From the tables it is found that the final state is then $t = 44.25$ deg., whence $r = 16.13$ and $r = 0.37$ grams, or

$$0.39\ (202 - 44.24) \times 0.0128 = (44.25 - 15)\ 0.0194 + 0.00037 \times 575.6$$

On the other hand, the mixture of air and gasoline passes at the temperature of 187 deg. and the pressure of 7.62 kg. These two equal volumes of carburated air and wet steam are now mixed. According to the tables 212.8 liters are saturated by 33.2 grams of water at 63.1 deg., which corresponds to a tension of 0.237 kg. per sq. cm. The heat lost by the gas in cooling to t deg. will then serve to raise the internal heat of 13.17 grams of water vapor from 44.25 deg. to 63.1 deg., and to superheat it from 63.1 deg to t deg.; also to raise 19.03 grams of liquid from 44.25 to 63.1 deg. and to vaporize and superheat it to the same temperature of t deg., whence $t = 117$ deg.

In fact

$$(187 - 117)\ (1.190 \times 0.170 + 0.0596 \times 0.35) = 0.06585 + 0.39 \times 0.01317\ (117 - 63.1) + (63.1 - 44.25) \times 0.01903 + 0.01903 \times 562.3 + (117 - 63.1)\ 0.39 \times 0.01903.$$

The pressure of the vapor equals $0.237 \times (390/336.1) = 0.275$ and this pressure is equal to $7.62 \times (390/460) + 0.275 = 6.74$ kg.

The exponent of the polytropic transformation is given by

$$6.74 = 4.7\ x \times 1.033, \text{ where } x = 1.21$$

and the work of compression as determined by the above formula is 9.34.

Explosion. By similar reasoning the theoretical pressure is found to be 52.61. The work according to the same conventions is then represented by

$$52.61 \times \frac{0.381}{0.31} - 9.34 = 55.2$$

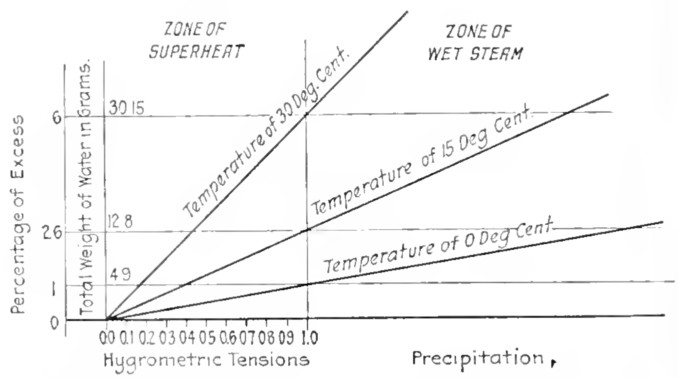

Fig. 9 Nomographic Curve of Corrections for Air Humidity

instead of 58.6, which was the value found for 15 deg. cent. and absolute dryness in the first case.

Discussion of Results

The foregoing shows the method adopted, which is applicable for every case.

In Case 1 it is found, as might have been expected, that at absolute dryness and any temperature whatsoever the work performed is the same in all cases, which is due to the fact that the carburetor is supposed to bring the gas to a temperature of 15 deg. always and to maintain the gasoline content in the mixture constant.

With constant humidity the work as calculated diminishes with increase of temperature. That is why the values found at 0 and 30 deg. and absolute humidity (saturation) are respectively 58 and 55.2. Therefore, it would be necessary to multiply the value obtained for power output in the test by a coefficient which might vary from 1.01 to 1.06. This indicates that the error from this source is by no means negligible.

For the same temperature the increase in power output is materially proportional to hygrometric tension and, therefore, the law of correction may be quite simply represented by a nomographic curve such as shown in Fig. 9. There the hygrometric tensions are indicated as abscissæ and the percentage by which the power read off the instruments should be increased as ordinates. The corresponding points for the same temperature are found to be located along straight lines passing through the region. On the other hand, care should be taken that the hygrometric state of the air does not go below 0.30. It may be admitted that the average state of the air is about 0.65 and it is

more practical to refer the constants for a motor to this average state rather than to the state of absolute dryness. A simple transformation of Fig. 1 shows that then the coefficient of correction may vary from 0.975 to 1.025. The extreme deviations with reference to operation under the average hygrometric state (0.65) are less important, namely, 2.5 per cent either way instead of 6 per cent in excess of the reading. Nevertheless in acceptance tests their value remains quite important.

Saturation with Precipitation

If the air sucked in by the motor contains droplets of water in suspension, the presence of this liquid should be taken into consideration. The problem is then treated in the same manner as the second case above referred to from the moment of an appearance of condensation.

If the corresponding points for the same quantity of water (vapor or water of condensation) contained in the air are calculated, it is found that the coefficient of correction is essentially the same no matter what may be the temperature under consideration. Hence, if the corresponding straight lines in Fig. 9 for each temperature be extended beyond the abscissæ for 100 per cent, the points corresponding to the same total quantity of water will be found to be essentially on the same ordinate, which may be graduated in percentages of increase of magnitude of power output or in units of water. The values already calculated make it possible to determine the scale of graduation without much trouble. It is found as a matter of fact that within the limits considered the power output should be increased by approximately 1 per cent for each 5 grams of water contained in 1 cu. m. of air.

Variable Atmospheric Pressure

If the foregoing calculations are carried through with a pressure H other than 760 mm. it is found that the results obtained under the same conditions of temperature and hygrometric tension are materially in the ratio of $H/760$. This is particularly so in one of the most unfavorable cases, say, 30 deg. cent. temperature and saturation, since then the water tension 0.043 is of material importance as compared with the atmospheric pressure; still the two coefficients calculated for $H = 760$ and $H' = 0.9$ do not differ from each other except by fractions of one per cent. The barometric correction must therefore be applied in addition to the combined temperature hygrometric correction.

Specific Fuel Consumption

The calculations indicated above give all the elements necessary for evaluating the various specific fuel consumptions. It is found that air humidity has only a very slight influence on the specific fuel consumption and affects it under the most unfavorable conditions to the extent of barely 2.5 per cent. It would appear, therefore, that in practice the increase of specific fuel consumption due to humidity of air falls within the range of errors of reading, of indicating instruments, and of such other errors which are generally covered by the tolerance in determination of experimental results.

All the above results apply to the case of carburetors capable of regulating the temperature of the gas so that it will remain at 15 deg. cent. and of maintaining the mixture in the ratio of gasoline to air of 1 to 20, which is the case with all modern carburetors.

As a matter of fact, however, the preheating never carries the gas to 15 per cent at the instant of admission. This temperature has been selected only as a basis, because it permits the operation of suction carburetors, but it is *a priori* evident that power is gained by maintaining the feed at the lowest possible temperature, or rather would have been gained if there were no danger of condensation of fuel or even congelation of atmospheric vapor as happens all the time with injection carburetors regulated by needle valves in winter.

A computation with zero temperature and dry air will show for τ a value of 61.7 instead of 58.6 under the assumed standard conditions, or a gain of more than 5 per cent.

Because of this, designers do not try to push preheating beyond a few degrees above zero. There is no difficulty in remaking the above calculations, for example, on the basis of heating the gas to 5 deg. and coming still closer to actual conditions by introducing a suitable coefficient of throttling.

Comparative results will be approximately the same, as might have been seen from the start—the effects of lesser heat and reduced admission compensating each other.

Engines with Forced Water Injection

There is no contradiction between the results that have been indicated and those actually obtained on engines with forced water injection, such as the Capitaine-Banki type. All the above considerations had reference to an engine with a normal volumetric compression equal to 4.7. In the Banki motor the volumetric compression went as high as 9.82 and the amount of water injected at full load was 4.84 times the weight of the gasoline, while in the example considered earlier (with the temperature of 30 deg. cent.) the weight of water was only 0.53 times that of gasoline, or one-ninth of that in the Banki motor.

A brief calculation applying the above-discussed principles to the Banki motor is given in the original article. (*La Technique Moderne,* vol. 10, no. 6, June, 1918, pp. 266-269, 1 fig., *e*)

MACHINE ELEMENTS

Sykes Flexible Reversible Coupling. Description with illustration of a flexible coupling made by a British concern. Broadly, it is constructed after the fashion of a crab coupling, one half being provided with pockets, the number of which is determined by the size and duty of the coupling. This portion is keyed on to the half-flange coupling on the shaft, the pockets being designed as in a crab coupling, to receive the radially disposed tenons on the other member, which is keyed on to the motor shaft. Flexibility is obtained by the insertion of rubber blocks, a coupling being assembled so that the rubber is under compression. Hence, as the driving block is further compressed, the idle block expands and prevents backlash.

Provision for longitudinal expansion is accomplished by not pushing the tenon portion right home in the pocket when assembling, but allowing a space between it and the inner face of the pocket.

Slight tilting in the event of the shafts getting out of alignment has been allowed for by forming an annular concave recess on the inner face of the half-flange coupling, so that while the rubber blocks allow slight tilting to take place, the recess permits the end of the tenon portion to accommodate itself to the new position.

It is claimed that such an arrangement is superior to the ordinary spring coupling, because in the latter the flexibility depends upon the springs which must be designed either for the maximum load or for average load. In the first place they possess relatively no flexibility at light load, and in the second place they become practically a solid coupling at heavy loads. The use of rubber provides a degree of latitude in flexibility claimed to be impossible with springs, while its elastic qualities enable it to readily absorb shocks from impulsive loads. (*The Iron and Coal Trades Review,* vol. 98, no. 2667, April 11, 1919, pp. 437, 2 figs., *d*)

MECHANICS

Investigation of Rigidly Connected Reinforced-Concrete Frames

Analyses and Tests of Rigidly Connected Reinforced-Concrete Frames, Mikishi Abe. Discussion of the mechanics of rigidly connected frames and formulæ for moments and other indeterminate quantities for several types of indeterminate structures derived by a method involving the use of the prin-

ciple of least work; also data of tests on frames designed according to the formulæ found by the analyses. The paper is far too extensive to be suitable for abstracting and only the conclusions and general comments of the author are here reproduced.

1 Considering the errors involved in the measurement of the deformations and in the determination of the modulus of elasticity of the concrete, as well as those due to assumptions with reference to the distribution of stresses across the section and over the gage length, the results presented indicate a fair agreement between analyses and tests and justify the conclusion that the formulæ given in the bulletin for statically indeterminate stresses as applied to reinforced-concrete structures will give values for stresses in the members well within the limit of accuracy required in design.

2 The elastic action of the frames under external load and the manner of stress distribution along the members of the frame agree fairly well with the analyses given.

3 The location of the point of inflection in the members of the frames under load agrees closely with the location found by analyses.

4 If a frame is carefully designed and well reinforced, there need be no anxiety as to the rigidity of a joint. Effective continuity of members has been found in the tests.

5 No sudden failure took place in the frames tested. The increase in the deflection was uniform, indicating as great reliability for reinforced-concrete frames as for steel structures.

6 The load at which the first fine crack appears near the juncture of members is increased by fixing the lower column ends of a frame. This is obviously due to the increase in horizontal thrust at the lower column end over that developed when the lower end is free to turn.

7 At sharp inside corners, high compressive stresses were developed in the concrete due to so-called curved-beam action and in several cases local failure occurred by the crushing of the concrete at these corners under high loads.

8 A slight deviation of the axis of vertical members from a vertical line, that is to say, a slight "out-of-form" of the vertical columns, produced an appreciable variation in the stress distribution in the frame.

9 Owing to the existence of a horizontal thrust (which varies from $P/8$ to $P/18$ in most common cases of simple frames) at the ends of a vertical or inclined member, it is advisable to incline the member slightly toward the direction of the reaction at the end. Such arrangement will greatly reduce the bending stress in the member. If this arrangement is not practicable, a slight increase in the top width of a vertical member and a slight decrease in its bottom width, brought about by inclining the inner surface and making the outer surface vertical will add materially to the rigidity of a frame without a proportional increase in the amount of material used.

10 For a frame having an inclined column, it may be possible to select the form of frame in such a way that the column will take no bending stress throughout its length.

11 Due attention should be paid to the rigid joint of a tie member to insure the stiff connection with a main member. A marked tendency to cause a sudden breaking of such a joint was found to accompany an increase of bending moment in the main member.

12 The use of a footing rigidly connected to the lower end of a vertical member is advisable, for it will reduce the bending moment at the juncture of the vertical and inclined members. A frame having such a footing is solvable analytically, since it approaches the case halfway between that of the hinged end and that of the fixed end of the vertical member, provided the foundation is sufficiently unyielding. A little consideration is needed to provide proper reinforcement at the juncture of the column and the footing.

13 The formulæ derived by analysis may be applied to a variety of forms of frames and are of wide applicability. (*Bulletin No. 107 of the Engineering Experiment Station, University of Illinois*, 106 pp., 59 figs. and 16 tables, *pc A*)

POWER GENERATION

Interconnection as Means to Reduce Necessary Steam Reserves, L. J. Moore. Article based on experiences in central California where important benefits have been realized by tying together various power systems.

One of the important advantages obtained by the interconnection of neighboring transmission systems operating hydroelectric plants with steam reserves is the reduction of steam reserve necessary to maintain reliable service.

This is brought about in two ways: (1) by the improvement of diversity factor due to connecting together of dissimilar groups of load; and (2) by the pooling of water resources.

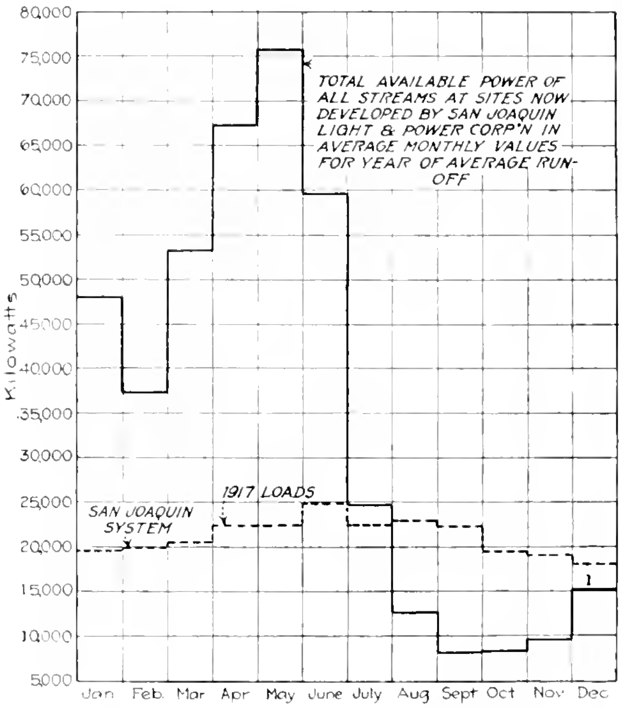

Fig. 10 Curves Showing the Necessity for Water Storage for Steam Reserve in the San Joaquin Valley, Southern California

The interconnection of three power and light systems operating in the central and southern districts of California is described and discussed in the present article. One of these systems is provided with a 45,000-acre-ft. reservoir for water storage, and two steam reserve plants (one 12,000 kw. and the other 2000 kw.). The second system has a water-storage reservoir of 88,000-acre-ft. and a big steam reserve plant. The third system has no water-storage facilities, but does have a 5000-kw. steam plant.

In addition, one of the companies operates at 50 cycles and the other two at 60 cycles.

The necessity for water storage or steam reserve for hydroelectric plants operating in this region is shown in the curve in Fig. 10 applying to one of the systems. This curve shows the heavy flow in spring and early summer when the plants cannot utilize all the power and the low discharge during the late summer and fall which makes it necessary for plants on this system to be supported by either storage or steam reserve unless they are utilized simply as minimum flow plants.

The flatter curve shows the load on the system for the year 1917 and makes evident the effect of the water-storage reservoir which made it possible to carry the entire load by water.

The article describes in some detail the conditions prevailing in the district and the manner in which the interconnection was effected. Because of this interconnection some of the plants at flood times are run at full capacity, permitting the other parts of the systems to increase their water-storage facilities.

Interconnection of systems operating at different frequencies made frequency changes necessary. Typical results on August 10, 1918, before the installation of the frequency changer, are shown in Fig. 11. The two lower curves show the Edison delivery to the San Joaquin system (the entire Kern River No. 1 plant was running at 60 cycles at the time) and the Mount Whitney demand at Strathmore. The separation of these two curves measures the amount of power the San Joaquin system was absorbing or delivering. These values added algebraically to the load of the San Joaquin system, had no interconnection existed, give the actual power delivered by the San Joaquin plants. The effect on diversity factor in direction of flow of power at Strathmore are evident. This flow has been controlled somewhat on the day shown by variation of the load on the Visalia steam plant, but the fact remains that in practice often one system may be delivering power to the other at a time of light load for itself and peak load for the other, when within a very short space of time the conditions may be completely reversed. This means that they help each other over peaks without the excessive use of steam necessary if they were all operating separately.

The Edison company realizes a saving in delivering power to the Mount Whitney in this way and preventing operation of the Visalia steam plant even at the expense of operating the Long Beach or Redondo steam plant, on account of the much greater efficiency of these two plants. It even pays to let San Joaquin's Bakersfield plant supply the difference, for the reason that Bakersfield is both more efficient than Visalia and because the plant is situated near the oil fields. Delivery of oil to the fire room is much less expensive, and besides a large quantity of natural gas is burned. A gas pipe line connects the Bakersfield plant directly with the oil fields.

The operation of the interconnected system on July 20, 1918, is indicated by Fig. 12, which represents conditions just before low water had raised the Mount Whitney demand and decreased the Edison delivery; as a result a considerable quantity of power was delivered to the San Joaquin company.

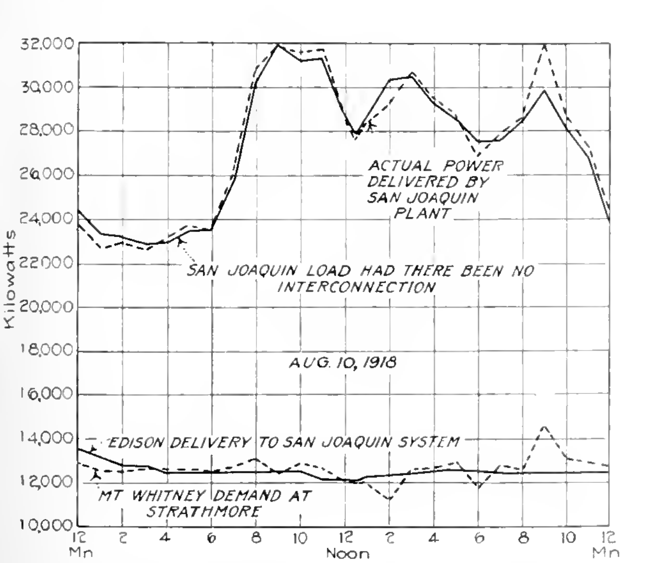

FIG. 11 TYPICAL RESULTS ON THE SOUTHERN CALIFORNIA SYSTEM BEFORE INSTALLATION OF FREQUENCY CHANGERS

When one of the 50-cycle impulse wheels at Kern River No. 1 is operating at 60 cycles it is found that the water necessary to generate 5000 kw. at 50 cycles generates only about 4500 kw. at the higher speed. Furthermore, the field current is only approximately two-thirds of normal under this condition. The San Joaquin's prime mover on Kern River is a turbine instead of an impulse wheel, but it gives somewhat analogous results in that a slightly higher output is obtained with the same water when operating on the Edison 50-cycle system. The field current is proportionately higher, too. No particular difficulties are experienced. In fact, the operation is quite satisfactory. (*Electrical World,* vol. 73, no. 17, April 26, 1919, pp. 840-842, 4 figs., *d*)

POWER PLANTS

HIGH-PRESSURE STEEL ECONOMIZERS AT KANSAS CITY. The conditions of boiler operation of the present day lead to increasingly high flue-gas temperatures and great weight of gases passed in a unit time interval. These conditions are very favorable to

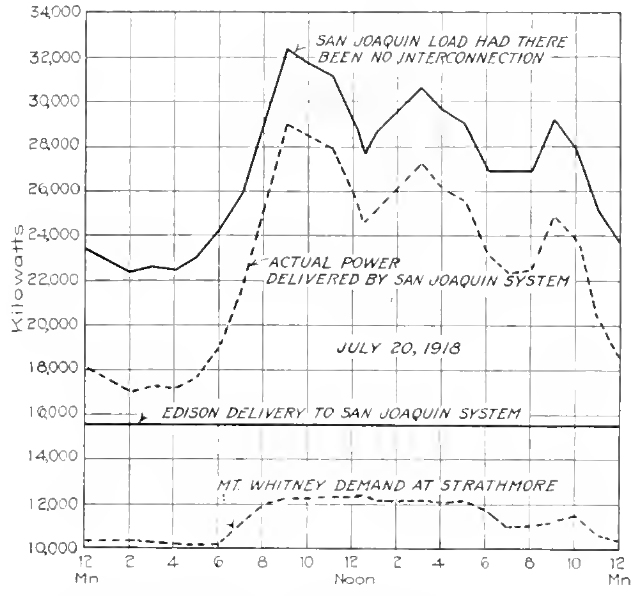

FIG. 12 CONDITIONS AFTER INTERCONNECTION BUT JUST BEFORE LOW WATER HAD RAISED MT. WHITNEY DEMAND

the employment of economizers especially with large boilers. On the other hand, they raise the question of proper materials to be used for economizers.

Cast iron has given efficient and safe service for pressures now common, but it is uncertain whether it will do for pressures of 300 lb. or more. Steel which would be safe for these pressures is, however, not so durable as cast iron, and condensation of the vapors in the flue gas on the relatively cold tubes results in rapid corrosion, especially if the cold steel is high in sulphur. Nevertheless, steel will have to be used if boiler pressures go up still higher and, for example, at around 1000 lb. cast iron would be entirely out of the question.

In the new power station now being erected for the Kansas City Light and Power Company this problem has been met by dividing the economizer into two sections, a high-pressure and a low-pressure section.

The low-pressure section (cold part) of the economizer is of cast iron while the hotter part, which is the high-pressure section, is of steel construction something like a section of a Stirling boiler.

The feedwater has to be pumped first through the low-pressure economizer into a tank which forms a suction tank for the boiler-feed pumps by which it will be pumped through the high-pressure economizer and into the boiler. The economizers are so proportioned that the water is to be heated in the low-pressure economizer to a temperature not over 200 deg. fahr., which will prevent the formation of steam in the low-pressure economizer and at the same time put the water into the high-pressure economizer at a temperature sufficiently high to prevent any condensation there. In this way the condensation and consequent corrosion is confined to the low-pressure sections where leakage and deterioration are much more easily controlled.

The high-pressure economizer is made up of two 36-in. drums, 23 ft. long, having 306 3¼-in. cold-drawn seamless tubes ¼ in. thick, arranged in 38 sections of 8 tubes each, front to back.

Each high-pressure economizer contains 4205 sq. ft. of heating surface and, moreover, is so baffled that the gases are compelled to pass over the tubes transversely three times. It is supported from the building steelwork, the support being at the upper end so as to be free to expand downward. The economizer is inclined 35 deg.

Each low-pressure cast-iron economizer, of the Green type, has 336 12-ft. tubes, 7 tubes per header, with a total of 5500 sq. ft. of heating surface. Each economizer is 16 ft. 11 in. long and the outside overall width is 16 ft. 2 in. The induced fans, one for each boiler unit, are of the multivane type, with two single inlets, driven by one 150-hp. slip-ring induction motor. Each boiler and economizer is intended to evaporate 80,000 to 100,000 lb. per water per hour, going up to 120,000 lb. per hour when forced. (*Power*, vol. 49, no. 15, April 15, 1919, pp. 556-557, 1 fig., *d*)

PUMPS

Submersible Motor-Driven Pumps for Salvage Work

Submersible Salvage Pumps and Engines. Description of a type of pump extensively employed of late by the Salvage Section of the British Admiralty and, as far as known, not previously described in full.

This machine consists of a centrifugal pump directly connected to an electric motor, so designed that it is capable of indefinitely operating while submerged in water.

It frequently occurs in the earlier stages of salvage operations that if powerful pumps can be brought to work immediately, there is a good chance of success, but a short delay may mean total loss or, at best, a much greater expenditure of time and money. In such cases the time required for rigging steam or oil-driven pumps is too great while a salvage vessel carrying submersible electric pumps can run alongside the wreck and in a very short time have the pumps working with current supplied from dynamos on board. This has in fact been done on several occasions by Admiralty salvage vessels. The S. S. *Westmoreland*, worth over £2,500,000, was salvaged in this way under circumstances in which no other kind of pump could have been employed.

The submersible electric pumps when at work are usually suspended by a rope from a derrick, or any other convenient part of the wreck, and will work in any position. One of these pumps was recently put to work on a vessel which had capsized, and continued to work at its maximum output while the vessel was being righted to an angle of 90 deg.

When the compartment in which it was situated was unsealed, the pump was found to be upside down and to have rolled to quite a different position to that in which it was placed.

Since it is not always convenient to supply current from a salvage vessel, an oil-engine-driven dynamo had to be developed which would be waterproof and unaffected by water conditions. This is especially important for use in tidal waters where the engine may have to remain in position while the tide rises and completely submerges the plant. An engine type has been developed which is capable of being covered with water without coming to any harm. The engine cannot, of course, work while submerged.

The means adopted to permit the engine to withstand submergence in water are very simple, but required a large amount of experimentation in working out.

The foremost characteristic is that the engines have a very plain outline. Every possible part of the mechanism is arranged inside the trunk or crankcase, and those parts which protrude are of very robust construction. In order to prevent water from getting into the interior of the engine all the openings such as the inlet and exhaust are provided with easily attachable covers and the crankshaft where it emerges from the crankcase passes through a stuffing box. The gland of this stuffing box is left slack when the engine is running and only screwed up in the event of probable submergence. In a test after a submergence of 24 hours only about two pints of water had found their way into the crankcase while the electrical fittings were unaffected. The whole of the ignition gear (both magneto and battery) is enclosed in a gun-metal case with a good-fitting cover.

Two types of this engine are now built: one with two cylinders of 12 b.hp., and the other with four cylinders giving from 45 to 50 hp.

The oiling system in these engines is of the same general type as that used in the Allen high-speed steam engines, that is to say, oil is pumped into a duct cast in the bedplate and led up through the hollow pedestals to the main bearings. Thence, some of it finds its way through holes drilled in the crankshaft to the crankpins and big ends, while the hollow connecting rods take the supply up to the gudgeon pins.

The construction of the motor has been generally known for some time. The water is actually encouraged to enter for the purpose of cooling the machine and the windings are protected by the simple expedient of making them from one piece of heavily rubber-covered wire. Because of the ample cooling made possible by admitting the water, rubber insulation becomes permissible and this is the only waterproof material that seems to meet the requirements. The squirrel-cage type has been adopted, as it makes electrical connections with the rotating parts unnecessary.

The pump itself is of the usual single-inlet pattern with a gun-metal impeller. The 4-in. pumps are capable of delivering

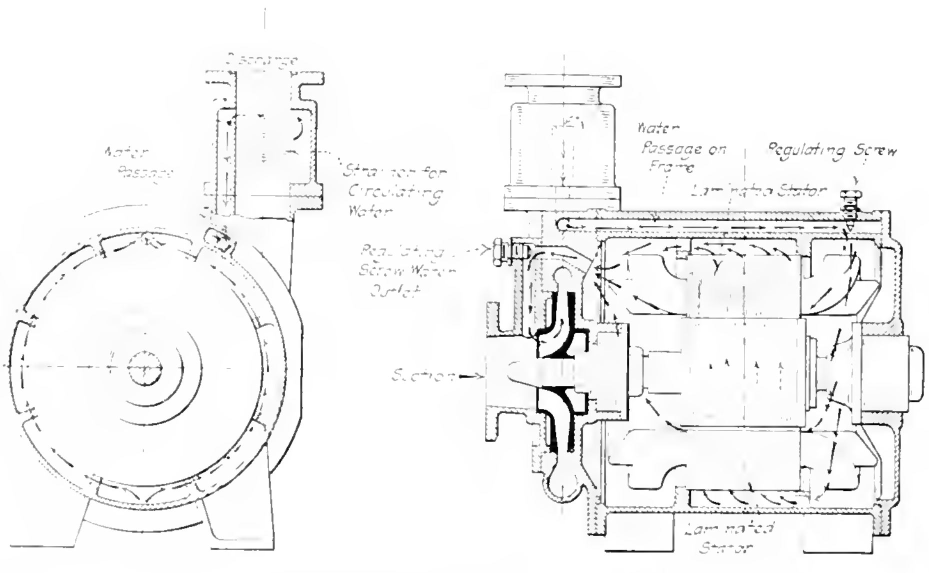

Fig. 13 Sections Through Submersible Pump and Motor Used by the Salvage Section of the British Admiralty

100 tons of water per hour against the head of 75 ft. and require 17 kva. The largest set built is 18 in. and is capable of raising 1750 tons per hr. to a height of 30 ft. Fig. 13 gives a section through the pump and motor. Unfortunately the illustrations showing the engines are not suitable for reproduction. (*The Engineer,* vol. 127, no. 3299, March 21, 1919, pp. 274-276, illustrations on page 278, 9 figs., *d*)

RAILROAD ENGINEERING

Water Treatment on the Great Northern Railroad, C. Herschel Koyl. East of the Rocky Mountains the Great Northern crosses a strip of country 600 to 700 miles wide where the water not only contains a considerable amount of mineral matter but is also very irregular in its composition, being sometimes alkaline and sometimes hard; and during the past six years it has been developing a system of water treating adapted to its special purposes.

The methods developed have now given water satisfactory for its content of sodium sulphate over a strip of 1100 miles.

The character of the chemical treatment of the water varies with the character of the water, but all cases are covered by the use in proper proportion of hydrated lime, soda ash (sodium monocarbonate) and sulphate of iron (ferrous sulphate).

The purpose of using hydrated lime is to neutralize carbon dioxide. Soda ash is used to replace the scale-making lime sulphate by a non-scaling medium sulphate, while ferrous sulphate is used in the first place for the treatment of the last grains of calcium carbonate so that it will not clog the injector pipe; second, for the conversion of caustic sodium hydrate into neutral sodium sulphate; and third, for the further weighing and more rapid settling of particles of light suspended matter. Treatment with ferrous sulphate is stated to be a device introduced by the author for the first time in this connection.

Important advantages are claimed to have been secured by the use of water treatment. Not only has foaming disappeared, but with freedom from leaks boiler operation became far more reliable. In this way a large amount of time was saved on the road, not merely because boilers did not leak and fail but also because the service became more dependable, and in this way speeding up of each department has been made possible.

The following illustration of what water treatment has done is given in a report from the master mechanic of one of the districts. Engines on a certain section used untreated water and a set of flues never lasted longer than six months. Since water treatment has been introduced the scale has all come off from stays, crown bolts and flues, and with the aid of a little kerosene the flues and sheets have been kept as clean as on the day the engine came out of the shop, notwithstanding the fact that it has been in service under the new conditions for 15 months.

On the other hand, no attempt has been made to reduce boiler washing, because on account of the concentration of sodium sulphate and sludge in the mud ring, the boilers are washed every round trip, same as before the water treatment was introduced.

Other important advantages are mentioned in the original article and a water-treating plant briefly illustrated. (*Railway Age,* vol. 66, no. 17, April 25, 1919, pp. 1053-1056, 1 fig., *d*)

VARIA

Fracture of Two Compressed-Gas Cylinders and the Cause (*Zeitschrift des Vereines deutscher Ingenieure,* March 8, 1919). The present writer made a most complete investigation into the cause of fracture of two compressed-gas cylinders—one for hydrogen and the other for oxygen—which burst while in course of filling.

The hydrogen cylinder was being filled with the gas at a pressure of 140 atmos. The explosion was extremely violent; the floor on which the cylinder was standing was found to have a hole in it 75 cm. deep; the flask or cylinder flew upward like a projectile, passed through the roof of the filling room, and fell in a garden some 85 m. distant.

An examination of the plant (compressor and fittings) revealed it to be in order.

The gas was produced electrolytically and collected in a gasholder, after which it passed into a two-stage compressor and was compressed to a filling pressure of 150 atmos.

A full chemical, mechanical and micrographic examination was made of the fractured cylinder, from which the writer concludes that it satisfied the requirements of the authorities. Probably a "fold" or crease formed in the steel while being mechanically treated, and this creasing gave rise to a crack or cracks, which were most likely the cause of the explosion.

He suggests that in addition to the prescribed precautions relating to the inspection of these vessels, each seamless vessel should be "flash-tested" (this test is not defined) before the head is put on, in order to find faulty places. This method has been adopted by the military authorities prior to the acceptance of all shells. This test would enable any creases to be discovered in the steel.

In the case of the oxygen cylinder a greater number of splinters were available.

The cylinder is said to have burst during the process of filling at a pressure of 80 to 100 atmos. The oxygen used was obtained from liquid air.

The cylinder was of similar construction to the hydrogen cylinder, being of the seamless-steel type. The same official regulations applied in this case also.

The article describes in detail the mechanical, chemical, etc., tests carried out on the fragments collected.

Numerous causes contributed to the bursting of the cylinder as shown by the experimental results.

The steel was weakened at one particular part where the test initials were stamped, as the stamp penetrated to half the wall thickness of the cylinder.

The steel was too brittle for the purpose in question. It was very sensitive to dynamic stresses.

The author suggests that the regulation regarding the stamping of these cylinders should be modified. The stamping should be reduced to a minimum, and be done when the steel is in a red-hot state.

A mere pressure test is, when employed alone, very defective. It is much more important to test the inside and outside surfaces and the thickness of wall of each cylinder prior to putting on the top.

Complete tables, illustrations, etc., accompany the above paper. (*Technical Supplement to the Review of the Foreign Press,* vol. 3, no. 9, April 29, 1919, p. 311, no. 4910).

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

The following statement of the National Advisory Committee for Aeronautics shows the development in airplanes which has been made since 1903. The first man-carrying airplane flights were made in December, 1903, with the Wright Bros. engine, developing 12 hp. and weighing 152 lb., or 12.7 lb. per hp. In 1910, the average horsepower for aeronautic engines had increased to 54, and the weight had decreased to 5.7 lb. per hp. After another 7 years, in 1917, the average power output had advanced to 243 hp., and the weight had decreased to 2.8 lb. per hp. In March, 1918, the Liberty motor developed 432 hp. for a weight of 808 lb., or 1.86 lb. per hp. At present, the Liberty motor is developing a maximum of 450 hp. for a weight of 825 lb., or 1.83 lb. per hp. The average consumption of fuel decreased from about 0.8 lb. per hp. in 1903 to 0.55 lb. in 1918, and for the Liberty engine to 0.50 lb. The present consumption is about 0.46 lb. per hr. (*Machinery,* p. 744, April 1919)

MECHANICAL ENGINEERING
THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Published Monthly by the Society at
29 West Thirty-ninth Street, New York

M. E. Cooley, *President*
William H. Wiley, *Treasurer* Calvin W. Rice, *Secretary*

PUBLICATION COMMITTEE:
George A. Orrok, *Chairman* J. W. Roe
H. H. Esselstyn George J. Foran
Ralph E. Flanders

PUBLICATION STAFF:
Lester G. French, *Editor and Manager*
Leon Cammen, C. M. Sames, *Associate Editors*
W. E. Bullock, *Assistant Secretary Editor Society Affairs*
Frederick Lask, *Advertising Manager*
Walter B. Snow, *Circulation Manager*
136 Federal St., Boston

Yearly subscription $3.00, single copies 35 cents. Postage to Canada, 50 cents additional; to foreign countries $1.00 additional.

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

It is proposed to publish in Mechanical Engineering for July a complete account of the Detroit Meeting. Inasmuch as the meeting does not end until June 19, the day before the usual closing date for the journal, the publication of the July number will necessarily be delayed several days. The volume of work entailed in reporting a convention is very large, involving as it does the summarizing of perhaps 600 pages of stenographer's notes, besides handling the written discussion; but it is hoped that it may not be necessary for the July number to be more than one week late in reaching its subscribers.

Major Fred J. Miller Joins the A. S. M. E. Staff as Consultant

Major Fred J. Miller has joined the staff of the Society in the capacity of consulting engineer and advisor upon its publications. In this he will coöperate with the Papers and Publication Committee in the development of Mechanical Engineering, which has made notable progress during the past year through the acquirement of The Engineering Index and the addition of other features of direct benefit to the practicing engineer.

Major Miller has served on the Council of the Society and on various committees and has been intimately acquainted with its activities over a period of many years. He was one of the earliest to advocate the establishment of the Society's journal, at first known as the Proceedings, and it is fitting that he should now be able to render additional service to the publication in which he has long taken so deep an interest.

For ten years he was editor-in-chief of the *American Machinist*, which reached a high plane of technical journalism under his direction and to which he personally made notable contributions that attracted wide attention. Following this he became Factory Manager of the Remington Typewriter Company. Shortly after the United States declared war against Germany he entered the service and organized and directed the Civilian Service Division at the Rock Island Arsenal. Later he went to the Office of the Director of Arsenals at Washington, when, at the request of the War Labor Board, he was detailed to the Bethlehem Steel Works. He has recently resigned from the service and is now in consulting practice. The Society is to be congratulated upon having at this time of progressive development the benefit of his sound judgment and long experience in publication and organization work.

The Spring Meeting

On the opposite page is given tentatively the complete program for the Spring Meeting of the Society to be held at Detroit, Mich., June 16 to 19. The papers for the meeting are being published progressively in Mechanical Engineering, the first appearing in the April number, and practically the whole of the technical section of this issue is given up to these papers.

Unusual interest attaches to the opening of the meeting on Monday because of the progress report to be presented by the large and representative Committee on Aims and Organization which has long been in preparation. On Tuesday morning there will be what is perhaps the most important, or keynote, session, on the subject of Research in Engineering, under the direction of the very active Research Committee of the Society. In view of the marked development in research work throughout the country and the recent reorganization of the National Research Council to promote and coördinate research, this session ought to have the attention of all the members in attendance. Several timely papers are to be presented, together with reports by three of the Sub-Committees on Research.

In the afternoon of Tuesday there will be a general session of non-technical character, such as is provided at each convention, for discussion of administration topics according to the current developments in the field of industry. The general theme will be Industrial Relations, with addresses bearing on the needs of the time for securing industrial peace and the recent movement toward greater representation on the part of employees in the conduct of the affairs of industrial firms.

Several papers on Wednesday morning, as well as at other sessions, are contributed by the Mid-West Sections, these constituting some of the best contributions offered for the meeting. They are indicative of the prominent place which the Sections have attained in the affairs of the Society and of the substantial assistance which they are rendering in building up the Society's publications through their contributed articles.

There will be one session under the auspices of the Gas Power Sub-Committee, a General Session for miscellaneous technical papers, and on Thursday morning a closing session very pertinent to the power-plant situation at the present time, for the discussion of fuels. There will be three papers on pulverized and crushed coal and one on oil fuel. In view of the fact that low-grade fuels are necessarily assuming a more important place in power-plant operation, and also that power-plant efficiency through the development of the steam turbine and improvements in steam boilers permits the use of high-pressure and superheated steam, the next step forward appears to be in the boiler furnace. Under these conditions the possibilities of fuel in finely divided or pulverized form becomes an absorbing subject for discussion.

The Detroit Local Committee has drawn on the wonderful resources of the city of Detroit for the entertainment of their guests and, as outlined in the program, there will be numerous excursions to industrial plants of very great interest. An afternoon and evening will be spent on the Lake and dinner served on the excursion boat. There will be an evening of music and dancing at Arena Gardens, and the Ladies Committee has arranged various entertainments for the visiting ladies, including motor trips, etc.

Records of War Service

It is intended to publish an account of service rendered by members of the Society in the World War.

To that end it is requested that every member of the A. S. M. E. who served in the Army or Navy, or who in any other way rendered direct service to the Government during the war, send to the committee a full account of his service. Address Committee on War Service, care of the Society.

SPRING MEETING PROGRAM

Detroit, Mich., June 16-19. Headquarters, Hotel Statler

Monday, June 16

10:00 a. m. Opening of headquarters and registration at Hotel Statler
10:00 a. m. Council Meeting
2:00 p. m. Business Meeting followed by Report of Committee on Aims and Organization
8:30 p. m. Address of Welcome by Mayor James Couzens. Reception and Dance. Refreshments

Tuesday, June 17

10:00 a. m. Professional Session

Research Session
(Under auspices of Research Committee)

The Present Condition of Research in the United States, Arthur M. Greene, Jr.
Research Work on Malleable Iron, Enrique Touceda
Reports of Sub-Committees on Flow Meters, Bearing Metals and Lubrication
The Organization and Conduct of an Industrial Laboratory, A. D. Little and H. E. Howe.

10:30 a. m. Trip to Burroughs Adding Machine Company. Luncheon at plant
12:30 p. m. Luncheon at Hotel Statler for Council and Sections Representatives
2:00 p. m. Professional Session

Industrial Relations Session

Industrial Personnel Relations, Arthur M. Young (contributed by the Chicago Section)
The Status of Industrial Relations, L. P. Alford
Certain Aspects of the Management Problem, Magnus W. Alexander

(Other speakers to be announced)

2:30 p. m. Trip to Morgan and Wright Company's Plant
8:30 p. m. Musical entertainment, Arena Gardens, 1253 Woodward Avenue. Dancing, Cards, Refreshments

Wednesday, June 18

10:00 a. m. Simultaneous Sessions

Sections Session
(Under auspices of Sections of Mid-West)

Central-Station Heating in Detroit, J. H. Walker (contributed by Detroit Section)
Production of Liberty Motor Parts at the Ford Plant, W. F. Verner (contributed by Detroit Section)
Fire Engines and the Essentials of Fire Fighting, C. H. Fox (contributed by Cincinnati Section)
Electrical Method for Measuring the Flow of Fluids in Pipes, J. M. Spitzglass (contributed by Chicago Section)

Gas Power Session
(Under auspices of Sub-Committee on Gas Power)

Crude-Oil Motors vs. Steam Engines in Marine Practice, J. W. Morton

(Other papers to be announced)

10:00 a. m. Trip to Connors Creek Plant of the Detroit Edison Company. Luncheon at plant
2:30 p. m. Steamboat trip through St. Clair Flats. Steamer Britannia leaves foot of Bates Street, returning at midnight. Dinner on boat. Entertainment, dancing, refreshments.

Thursday, June 19

10:00 a. m. Simultaneous Sessions

Fuel Session

Pulverized Coal as a Fuel, N. C. Harrison
Economy of Certain Arizona Steam-Electric Power Plants Using Oil Fuel, C. R. Weymouth
Pulverized Coal for Stationary Boilers, H. G. Barnhurst and Frederick A. Scheffler

General Session

Elements of a General Theory of Wing Design, Walter C. Durfee
Air Fans for Driving Electric Generators on Airplanes, Capt. G. Francis Gray, Lieut. John W. Reed and P. N. Elderkin
Mechanical Lifts, Past and Present, and a New Method for Their Balancing, Lieut. J. F. Robbins
General Equations for the Design of Riveted Butt Joints, A. A. Adler
The Economical Section of a Water Conduit, Cary T. Hutchinson (By title only)

Morning left open for special trips. Members are requested to indicate, upon arrival at headquarters on Monday, which plants they desire to visit.

2:00 p. m. Trip to Ford Motor Company, Highland Park

The Crossing

On May 26, 1819, an American ship, the *Savannah*, was the first steam-driven vessel to cross the ocean. One hundred years later, on May 17, 1919, an American seaplane fully commissioned as a ship in the United States Navy crossed from Trepassey Bay, Newfoundland, to Horta, on the Island of Fayal, Azores, making port in 15 hr. 18 min. after leaving ground at Newfoundland. (This is as far as the flight has progressed at the time of going to press.)

There are several elements in this flight worthy of the most careful consideration by engineers.

The ship was of the heavy-load-carrying type with its full water-landing equipment and wireless. Furthermore, it was of the multi-motor type, this also materially increasing its weight. The fact that a seaplane of this type could make a flight of over 1200 miles without forced landing, in record time for a craft of its weight, is a strong proof both of the high state of the development of aeronautical engineering generally and of the advance made in particular by the American Navy.

The working of an aeroplane, and in particular of the aeroplane engine, has been correctly compared to that of a racing car. Every part of the engine and plane is at full load under high stresses and moreover the aeroplane is in some respects in a less fortunate position than a racing car, because it is more subject to vibrations and does not have the damping protection of the road under the tires.

Because of this, there is a far greater tendency toward fatigue in both the engine and frame of the plane. A car that could make 1200 miles at the rate of 85 miles per hour without stoppage for adjustments and without engine or frame trouble would have been a very remarkable car, indeed, and yet the Navy seaplanes have done it.

This performance is also a proof that the Liberty engine, with which the seaplanes have been driven, has passed through the period of development and may now be considered as a fully completed product entitled to the highest consideration for its reliability of performance and economy in fuel consumption.

The American Navy has been famous for its proverbial luck. The flight from Trepassey to Fayal Island gives a little insight into the secret of Navy's "luck." Such a flight would have been impossible without the most careful preparation and in fact it would be no exaggeration to say that, roughly, the performance of May 17 is a direct outcome of work of close upon two years.

It would have been impossible unless everything had been prepared in such a manner as to work close to an efficiency of 100 per cent. The failure of a small part in the plane, of a few spark plugs in the engine, of some connecting rod, or valve push rod might have marred or made impossible the crossing, and the fact that the crossing has been achieved shows that everything from the large factors to the smallest details must have been approximately 100 per cent perfect.

Transatlantic passenger transportation will not follow right on the heels of the crossing by the Navy seaplanes. In fact, if anything, this flight has shown not only that it is possible to cross the Atlantic in the air but also that it is by no means easy to do so. Notwithstanding the elaborate precautions taken for guiding the fliers, the NC 1 and NC 3 lost their bearings in a dense fog and even the NC 4, which completed the flight, stopped at Horta instead of Ponta Delgada, the spot designated for landing. The NC 3, after being "lost" for two days, was discovered on May 19 only seven miles from the harbor of Ponta Delgada, proceeding under her own power, but the NC 1, after being located and taken in tow by a destroyer, was later wrecked through heavy seas.

Spurred on, doubtless, by the departure of the Navy squadron, Harry G. Hawker, the famous Australian aviator, made on May 18 his daring plunge from Newfoundland for the British Isles in the Sopwith biplane. Entirely unprotected against a fall at sea, and even without protection against a dangerous alighting upon the land in order to reduce the weight of his machine, he took the hazardous risk—and failed.

Nevertheless, in spite of the tremendous difficulties to be overcome, a start has been made in the air voyages across the Atlantic.

Thirteenth Engineers Return to Chicago

The Thirteenth Railway Engineers recruited from the six railroads which center in Chicago were given a most royal welcome upon their return to that city on May 12. Approximately 10,000 people are reported to have lined Michigan Boulevard to witness the parade, which was reviewed by Major General Black, Chief of Engineers; Colonel R. D. Black, general staff, and one of the organizers of the Thirteenth Engineers; S. M. Felton, president of the Chicago Great Western; and W. L. Park, federal manager of the Chicago Great Western, and chairman of the reception committee. Major General Leonard Wood was also to have reviewed the regiment but was caught in the crowd at one of the street crossings and was unable to pass. The parade started at 11.30 with Colonel C. L. Whiting in command. As the men marched along Michigan Boulevard the engineers on the Illinois Central and other railroads opened their whistles and the resulting din silenced the famous band of the regiment. Following the parade the men were dined and entertained and later entrained for Camp Grant where they will shortly be demobilized.

The Thirteenth Regiment was largely an operating unit and during the greater part of their stay overseas were engaged in transporting troops and munitions in the Argonne and St. Mihiel sectors. The regiment is credited with having moved 103 trains of men and munitions during a period of only 24 hr. They also operated the trains which carried the famous 14-in. Navy guns.

Past-President Henry R. Towne Reaches a Business Anniversary

A souvenir booklet of historic value has been issued by the Yale and Towne Manufacturing Company, of which Henry R. Towne, Past-President, Am.Soc.M.E., was one of the founders. It is issued as a Semi-Centennial Souvenir of the company, and contains, besides a history of the works, an account of the various men who have contributed to its upbuilding and various other data and information concerning the organization, products, war activities, etc., of the company.

The birthplace of the Yale industry was at Newport, Herkimer County, New York, where, about 1840, Linus Yale, Sr., began the manufacture of "pin-tumbler" locks. His son, Linus Yale, Jr., a talented and ingenious inventor of locks, formed a partnership with Henry R. Towne, which resulted, in October, 1868, in the organization at Stamford, Conn., of what is now The Yale and Towne Manufacturing Company. Mr. Towne undertook the manufacturing management of the company. The corporation was organized in 1868, with Mr. Yale as president, but upon the latter's death, a month later, Mr. Towne succeeded as chief executive and president, and continued in that position until his resignation as president in 1915 to accept the chairmanship of the Board.

The products of the Yale firm, just prior to the formation of the partnership with Mr. Towne, were bank locks, seven varieties of key locks, and the metallic post-office lock box, the employees numbering about 35. The present daily output is 25,000 locks, with an organization under normal conditions of 3000 men.

Westinghouse Scholarships as War Monuments

E. M. Herr, president Westinghouse Electric & Mfg. Co., Pittsburgh, has announced the establishment of four technical scholarships by his company to commemorate the part played during the war by its employees. Selection of the candidates will be determined by annual competitive examination conducted by the company's educational department under the direction of a committee consisting of three vice-presidents, who will also prepare the regulations and all details of administration. Each scholarship carries with it an annual payment of $500, and the student may take any course of engineering at whatever school he selects having the approval of the committee. Scholarships are for one year only, but will be continued for four full years provided the student maintains the standards required by the institution he has elected to attend. The number of new scholarships will be four each year. (*Iron Age*, May 8, 1919.)

Aims and Organization Committee

A COMMUNICATION on Standardization of Aims has been prepared by James Hartness, Past-President, Am.Soc.M.E., and member at large of the Aims and Organization Committee of the Society, for the consideration of the Sub-Committee on Relations of the Mechanical Engineer to His Work. From this communication the following extract has been taken which is of interest to those who are giving thought to present conditions and the general trend of events:

One of the points that I wish to emphasize is the importance of having an aim that fits the world's best ideals—an aim that will disarm all destructive isms.

We must aim to make the high special knowledge and experience of the engineering profession of value in guiding all the individual activities along lines of highest beneficial results to all people. We must select a slogan that everyone can understand, one that would put to shame any disruptive activity on the part of advocates of sham scientific or sham economic doctrines. We have reached a point where something more than argument and logic must be served out to the American people.

The war has started the functioning of something we call the heart, and this something, which for convenience we call the inner man, is a thing that dominates, is a thing that may be swayed by noble purposes or it may be stampeded into mob action. While educational institutions are instructing the brains, Bolshevism is stampeding the inner man. The lines of communication between the average highly trained engineer and the great mass of workers are absolutely down. For instance, the engineer thinks that he can direct mechanical and industrial activities by specifications and drawings issued from some central office. The workers know that specifications miles long and diagrams that would cover the whole continent cannot give sufficient direction to enable him to skillfully perform certain operations. We know the ship cannot be rigged and the industry cannot be economically and successfully operated without special skill and ability in each of the jobs, from the highest skilled down to the lay president's job.

In view of this, engineers who insist on disturbing the workers by office type of management should be looked upon as drags and menaces, and The American Society of Mechanical Engineers should make for its chief slogan "FITNESS FOR SERVICE," with the interpretation of fitness that includes enthusiasm, optimism, good will, noble purpose, integrity, appreciation of the other fellow, readiness to pay in honor and tribute as well as cash, and to admit, to begin with, that the real people in this world are those who are rendering an effective service in an essential work.

The inner man is now deeply stirred throughout our whole land, and if we go on and talk of refinements of organization; if we go on drawing diagrams, showing the relative position of each officer; if we go on issuing tabulations of dimensions in three- or four-place decimals of the inch relative to the sizes of rubber bands and screws when not under tension, we will be living in a fool's paradise. It is one that is sorely threatened at the present time, and there should be an awakening even of the so-called highly cultured people that will match and help to head off the stampede of those who are doing things with their hands.

When we get the right slogan: "Fitness for Service," the administration of our railroads, of our coal distribution, and in fact every other part of our glorious republic will be properly handled. Then, the affairs of this great industrial country will be handled by men competent to manage such things; committees for investigating industries will be composed of men with practical industrial knowledge and experience; political preferment will pass away.

Then the influence of the speculator in Wall Street will vanish, and the men of Wall Street will stay where the war has put many of them—in positions in which they are rendering essential service; men who have been struggling for special laurels of wealth will be struggling to attain the higher laurels of real value, the new and true standard of greatest service and greatest fitness for service. Then we will realize the vision of Washington, Lincoln and of the true leaders who are being born out of the travails of war. Then the activities of the country will no longer be handicapped by unwise guidance of labor.

The American Society of Mechanical Engineers must have such a slogan or it will gradually become farther and farther removed from the head of the procession. There is nothing so deadening to an organization as to lay behind general progress. It leads to indifference, to pride, and to all those things that are distinct menaces, and that is what The American Society of Mechanical Engineers is up against at the present time. We point to our growth in power and numbers and forget that we have a thousand times our present power and should lead the whole world in administrative as well as constructive achievement.

[The report of the Committee on Aims and Organization has now been drafted and will be presented at its meeting in connection with the Spring Meeting on Monday, June 16, at Detroit, Michigan, at 10 a. m. The Council is expected to receive the report and to order it transmitted to the semi-annual business meeting at 2 p. m. on the same day, where it will be thrown open for discussion by the membership. To prepare the field for this discussion a preliminary draft of the report has been referred to the members of the Committee for them to discuss with the Sections they represent and to this end several Sections have already arranged special meetings.—EDITOR.]

Spokane Engineers Want to Meet You

Mr. A. D. Butler, Secretary, Spokane (Wash.) Engineering and Technical Association, has sent a note to the Secretary saying it is the desire of his association to come in contact with engineers who may be going to that section of the country, or passing through Spokane. There is a meeting of some one of the committees of the association nearly every day in the week, and it would afford them much pleasure to have at luncheon any engineers who are in touch with important matters, at which time a gathering would be arranged to talk over the engineering field in general. Spokane engineers desire to keep well informed on problems in the different parts of the United States and to broaden their field of acquaintanceship.

Government to Give Motor Trucks to States

Twenty thousand motor trucks valued at more than $45,000,000 are about to be distributed by the Secretary of Agriculture through the Bureau of Public Roads to the state highway departments. These trucks have been declared surplus by the War Department and will be distributed to the states under the provisions of Section 7 of the Post Office Appropriation Bill. They must be used by the states on roads constructed, carried on in whole or in part by Federal aid. All that the states need do to acquire the use of these 20,000 trucks, which range in capacity from 2 to 5 tons, is to pay the loading and freight charges. Of the trucks to be thus given to the states 11,000 are new. All, however, are declared to be in serviceable condition. They will be apportioned to states only upon request of the state highway departments on the basis of the requests received from the respective states, and in accordance with the apportionment provided in the Federal aid law approved in 1916.

Three-Cylinder 60,000-kw. Turbine Installation

The largest turbo-generator and the first three-cylinder unit in the United States was placed in service on October 9, 1918, at the 74th Street station of the Interborough Rapid Transit Company of New York City. The new unit consists of one high-pressure turbine and two low-pressure turbines, each directly connected to a generator. When in normal operation all three elements are electrically connected. The turbines run at a speed of 1500 r.p.m., and each generator will deliver at that speed 20,000 kw. at 25 cycles (3-phase) and 11,000 volts. The new unit thus has a maximum continuous rating of 60,000 kw. It is also capable of carrying a load of 70,000 kw. for two hours. It occupies a floor space of 50 by 52 ft. When operating with a load of 40,000 kw., which is the most economical load, steam is supplied to the high-pressure element at 211 lb. per sq. in. abs. and a temperature of 250 deg. fahr. This is exhausted into the low-pressure turbines at a pressure of 29.7 lb. per sq. in. abs. and a temperature of 250 deg. fahr., and in the low-pressure elements the steam is further expanded to the pressure in the condenser (1 in. mercury abs. and 79 deg. fahr.).

The electrical features of the installation are of the most modern type. Each generator is protected by reactance coils and a relay system. Should a burnout occur in the windings of any generator, this relay system will at once disconnect it from the line. In addition to the usual governing mechanisms there has also been provided an arrangement whereby any turbine can be operated should the others, for any reason, be taken out of service. For example, if it becomes necessary to shut down the high-pressure element, each low-pressure turbine will automatically receive high-pressure steam. On the other hand, if both low-pressure elements are removed from service, then the high-pressure turbine will automatically exhaust to the atmosphere, but if only one low-pressure turbine has been removed, then the one remaining will still continue to receive high-pressure steam.

Since it is also necessary to control the three turbines when they are operated independently, each turbine is provided with a governor, which will immediately cut off the supply of steam if the speed exceeds a predetermined value. There is also provided between the high-pressure and low-pressure turbines a butterfly valve which will automatically close should the speed of the low-pressure turbine become excessive. In a similar manner, if the high-pressure turbines speed becomes excessive, then a governor will cut off steam to the entire system, and when the speed reaches a lower fixed value the governors of the low-pressure turbine will operate and admit steam directly to them. (*Electrical World*, May 10, 1919, pp. 933-935)

Advances in Automatic Control in Hydroelectric Plants

In the West, during the period of war stress, many helpful economies in power development were brought about that must inevitably be felt in the industrial life of the nation for many years to come. Not only was the production of fuel oil increased, but the generation and utilization of electric power both from water resources and from fuel supply was vastly forwarded. In some instances the task involved the establishment of new records in magnitude of engineering attainment such as the interconnected systems of long-distance power lines which have not been even approached in length of transmission or magnitude of distribution anywhere else in the world.

But perhaps the advances that have been made in automatic control will ultimately prove of even more lasting benefit to the industry in lessening labor costs, and hence in decreasing the cost of power production, than any other single cause.

The one-man cars for street railways, the automatic control of substations, such, for instance, as the new installation from Salt Lake City to Saltair in Utah, and the automatic control of power house generators as installed quite recently by the San Joaquin Light & Power Corporation, are forceful instances of this recent trend in economic design.

The Crane Valley power house of the San Joaquin Light & Power Corporation is of unusual interest. Here it is estimated that an average of over three million and one-half kilowatt-hours will be saved by taking advantage of power not hitherto used in the rise and fall of the lake level of Crane Valley Reservoir.

The unusual feature of variable head, ranging from 120 feet down to 80 feet, has been successfully overcome. This power house, in addition to a second installation below, is operated without attendants, and only the regular dam tender and reservoir tender make visits to the plant from time to time. An alarm system is installed in the caretaker's cottage so that he is notified if the machine is tripped off the line. The machine, in the meantime, may attain runaway speed. However, should the machine trip off the line and increase in speed, a centrifugal switch on the shaft of the unit closes a circuit on the wicket gate, operating a motor, which closes the wickets and shuts down the machine. The water in the ditch immediately starts to rise, and flows over the weir by-pass until such time as the caretaker of the plant arrives and puts the machine back on the line.

The recent advances in automatic control witnessed on all sides, combined with the irresistible trend toward outdoor switches and transformer stations, augur well for increased economic power generation and lend a certain hope to the power situation that is pleasing to contemplate. (*Journal of Electricity*, April 15, 1919)

U. S. Trade Commissioner

Secretary Redfield has appointed Alexander Luchars, publisher of *Machinery*, New York, United States Trade Commissioner to Great Britain, France, Belgium, Italy, Switzerland, Holland and Scandinavia, to study conditions in those countries affecting our engineering and machinery industries. Mr. Luchars' acquaintance with European manufacturers and engineers, and his connection with similar industries in this country as a publisher, will enable him to render effective service to American manufacturers. Mr. Luchars will spend about four months in Europe.

Production of Liberty Motor Parts at Ford Plant

(*Continued from page 522*)

the burrs on the inside or babbitted surface of the bearings. The fixture was made in halves, the lower half having a cylindrical section which served to hold the fixture in the machine. Ways for the slide carrying the broach were machined in the lower half, and also recesses cut for the hardened and ground blocks on which the parting surfaces of the work rested. The upper half was made in the form of a clamp, this part being bored to fit the half-section of circular hardened and ground steel liner, the inner surface of which fits about the outside of the work. Bosses bored for guide pins extended from the fixture and served to keep the halves in alignment. The weight of the upper half was disposed on springs coiled about the guide pins. The broach was of a semicircular section and bolted to the slide. This slide was connected to the ram of the machine. A copious flow of oil was kept on the work, keeping the locating block and broach free from chips and dirt. The cutting was done on the pull or regular stroke of the machine.

The Status of Industrial Relations

(*Continued from page 516*)

relations controversies. Such matters are justiciable today; they were not twenty years ago. We may look forward to a time when controversies in regard to such rights will become just as justiciable as any controversy in regard to property. It is possible that when this time comes it will be properly referred to as the era of industrial democracy.

Three tendencies in this development of industrial relations seem to be new though they are not novel.

The first is the acceptance of motive of service, which on moral grounds declares for recognition of the rights, needs and aspirations of every one engaged in or dependent upon industry. It is the engineering viewpoint rendered unselfish.

The second is the willingness to consider workers in groups. By training and experience the engineer has only been willing to look upon workers as individuals. Two of the governing principles that have brought modern industry to its present heights are the division of labor which minutely subdivides the job, and the selection and adaptation of the worker which individualizes him and attempts to fit him to some particular task, tool or machine. This is the viewpoint of specialization which deals only with units.

But in industrial relations the workers must be considered in groups or in the mass. This is the viewpoint of the industrial psychologist as contrasted with that of the technical engineer, and the latter has been slow to understand that his methods of subdivision and specialization cannot be used successfully in dealing with the problems of industrial relations. Much has been said about fostering coöperation, but little progress has been made. A reason for this situation is found in the lack of understanding on the part of industrial executives that to build *morale* or the *spirit of the organization* their working people must be appealed to in the mass and not as individuals.

The development of the safety committees began to open the eyes of industrial executives as to what might be accomplished once employees as a body had a chance to express their desires and opinions. The present movement to establish shop committees will carry this experience further and into new aspects of the problems of industrial relations. The experience so gained will show the possibilities and advantages of discarding the individualistic viewpoint of the engineer. It will also bring the passing of arbitrary and autocratic decisions.

The third tendency is toward mutual or joint control, toward mutuality and the working out of representation. It is an expression of democratic ideals.

From the experience of the past and in the face of the tendencies and forces now operating we may confidently expect a greater development in industrial relations during the immediately forthcoming years than in any preceding equal period of time. May engineers accept their entire responsibility and perform fully their duty in working out proper solutions of the problems presented!

ENGINEERING COUNCIL

Engineering Council[1] is an Organization of National Technical Societies of America, Created to Consider Matters of Common Concern to Engineers, as Well as Those of Public Welfare in Which the Profession is Interested

Conference on a National Department of Public Works

IN a recent number of MECHANICAL ENGINEERING announcement was made of the conference on the subject of a National Department of Public Works called by Engineering Council to meet in Chicago April 23 to 25. While in the years before the war a great deal of the engineering and construction work done independently by the different departments of the Government could probably have been accomplished more efficiently and expeditiously if placed under one directing head, the urgent need for such centralization of authority has only come to be generally recognized since the signing of the armistice.

Apart from the military engineering required for the conduct of the war, a vast quantity of civilian engineering was required, aggregating 800 million dollars' worth of hospitals, storehouses, railroads, waterworks, etc., which was carried through by the Construction Division of the Army, the personnel of which included a large number of the best engineers in the country.

The Construction Division's existence is, by law, to terminate 90 days after the signing of peace, and unless the maintenance and operation of these Government facilities, and the disposal of them where they are not to be maintained, are turned over to some board which is familiar with their details and requirements, chaos is sure to result.

It is proposed, therefore, that a Department of Public Works shall be formed, of which the present Construction Division of the Army, under civilian control, shall be a part. Also, that various other of the Government's engineering activities shall be consolidated under this new department for unified control.

The conference at Chicago for the consideration of the project was attended by 71 delegates representing 74 organizations, with a membership of over 100,000; and 7 members of Engineering Council and three members of the National Service Committee of the Council, these latter not as delegates, but with voting privileges. The Chairman of the Conference was M. O. Leighton, Chairman of the National Service Committee, and the Secretary, E. S. Nethercut, Secretary of the Western Society of Engineers, both elected by the conference. J. Parke Channing, Chairman of the Engineering Council, made the introductory speech, giving the purpose of the conference and setting forth the reasons why engineers urge the formation of a National Department of Public Works.

After a general discussion, the main question of the recommendation that such a department be established was referred to a resolutions committee, whose report was adopted as follows:

1 That the services and bureaus of the National Government having to do chiefly with matters of engineering and architecture, be grouped in one department to be known as the Department of Public Works.

2 That the Department of Public Works comprises those works which are built and operated for the use of the Public.

3 That the Department of Public Works be made available when desirable for the performance of special engineering and architectural work for the use of other Government bureaus.

4 That there be a systematic classification and organization of engineers, architects and other employees whose status shall be such that they may be recruited and maintained on merit.

Also, a committee on the scope of a Department of Public Works presented the following report, which was adopted:

1 That the establishment of a National Department of Public Works should be accomplished by grouping those Government bureaus, services, commissions and other activities whose functions are predominantly of an engineering or architectural character, in what is now the Department of the Interior and thereafter designating that department "The Department of Public Works."

2 That the transfer of any bureau, service or commission from any other department to a Department of Public Works should be accomplished without change of personnel, compensation and general plan of organization, leaving the coördination of the several activities, the simplification of organization and the establishment of additional bureaus such for example as a bureau of chemical engineering, to be effected as the need for the same may from time to time become apparent.

3 That in transferring river and harbor work and other work non-military in character, but now in charge of the Engineer Corps of the United States Army, to a Department of Public Works, the relation of the army engineers to such work be not changed and that there should be no relinquishment of non-military duty by the army engineers now on such duty until transfer of these engineers to military duty can be made without detriment to the public interests.

Your Committee finds that among the bureaus, services and activities, which logically belong to a Department of Public Works, are the following:

- A Bureau of Public Roads.
- The United States Reclamation Service.
- The Alaskan Engineering Commission.
- The Construction Division of U. S. Army,
- A Bureau of River, Harbor and Canal work, including such functions as are now exercised by the Mississippi River Commission and the California Debris Commission.
- A Bureau of Architecture.
- A Bureau of Surveys, including the Coast and Geodetic Survey,
- A Bureau of Mines.
- The Geological Survey,
- The Forest Service—at least until the same is divorced from the supervision of water powers and road building.
- The Bureau of Standards.

Your Committee believes that it would be unwise to determine at this time to what extent the proposed Department of Public Works should control the engineering activities of the General Land Office; of the National Park Service; of the Bureau of Lighthouses; of the Bureau of Indians Affairs, and of the Public Health Service and of various commissions, such as Commissions on buildings and grounds, and therefore suggests that such matters may well be deferred for consideration to a later date, preferably until the Department has been organized.

Following an extended discussion of ways and means for continuing the work of the conference and promoting the passage of a bill in Congress for the establishment of a Department of Public Works, a permanent organization was effected. It was voted that the conference should be designated as the Engineers, Architects and Constructors Conference on National Public Works, and that it continue in existence until dissolved by its own action.

An Executive Committee, a Committee on Text of Bill and a Campaign Committee were appointed.

[1] Officers of Engineering Council; J. Parke Channing, *Chairman;* Alfred D. Flinn, *Secretary*, Engineering Societies Building, 29 West 39th Street, New York.

NATIONAL SERVICE COMMITTEE

Contributed by the Washington Office[1]

Standardization for War Department

A SYSTEMATIC effort is being made in each Division of the War Department to make permanent the meritorious practices which grew out of the strenuous war experience. Because of the realization of the need of standardization there grew the Engineering and Standardization Branch of the Purchase, Storage and Traffic Division under the General Staff. This has shown that by working out standardization in all War Department specifications, savings at the rate of many millions a year can be effected in time of war and very material reductions in expenditures effected even with the army on a peace basis.

There are nine divisions under the General Staff which depend largely on engineering work for their operation—namely, Ordnance, Engineer Corps, Signal Corps, Construction Division, Chemical Warfare, Aircraft Production, Military Aeronautics, Quartermaster and Motor Transport Corps. Formerly each of these divisions had its own specification for each article purchased by the War Department. The electrical catalog, for instance,

[1] Washington Office in charge of M. O. Leighton, *Chairman*, National Service Committee, McLachlen Building, 10th and G Streets.

contains 25,000 items. Through the Engineering and Standardization Branch uniform specifications are being devised so that compact but complete catalogs for each class of commodity can be written up which will cover the requirements of every department. This at once simplifies the matter of specifications and purchases for the War Department, makes it possible for them to order in greater quantities and enables the manufacturer to get out his product and deliver it to the various departments at a maximum of efficiency.

Every effort is being made to accomplish the enormous task in a comprehensive and scientific manner. Authorities from various fields are being called in for consultation and wherever questions of engineering are involved Engineering Council, through its National Service Committee, has been called in to consult.

The organization of the Engineering and Standardization Branch is at present subdivided into research, production, inspection, standardization and catalog sections. The research section for instance, will make such investigations as are necessary to assist in standardization work and will arrange for definite forms of procedure in research work through various departments of the Government so that there will be not only standard methods but also standard departmental routine in which these methods will be followed. The production section will lay out definite schedules for quantity and specialty production, which they will recommend for use in the manufacturing arsenals and to individual manufacturers. The standardization of material will take place along lines that will insure interchangeability of a given article with the same article used in another department.

Information Service for Engineers

The National Service Committee of Engineering Council announces a National Legislative and Departmental Information Service for Engineers in all branches of the profession. The statistical, research and construction bureaus of the Government have become valuable sources of engineering information, but have not been used by engineers to the extent merited by the character of their material. Many matters before Congress involve engineering consideration, of which members of the profession should be aware. When in need of information from the above sources, or concerning congressional matters, set forth specifically what is wanted and address the National Service Committee, M. O. Leighton, *Chairman*, 502 McLachlen Building, Washington, D. C.

Scientific and Technical Employees of the Government in Washington Organized

Steps were taken for a permanent organization of the scientific and technical employees of the Government at their mass meeting on May 8, 1919. This was the result of an informal meeting on April 23 of 30 representative Government scientists and technical men who organized the preliminary committee and called the mass meeting. This subject has been widely discussed during the last year and was brought acutely to the fore by the work of the Joint Congressional Reclassification Commission, because that commission has stated that it wished to deal with employees only through organizations.

Rodney H. True of the Department of Agriculture, Acting Chairman, pointed out that the principal advantages to be expected from such an organization were: (1) Improvement of conditions and facilities for more effective scientific and technical work; (2) Adequate presentation of the needs and results of such work to the public and to legislative and administrative officers; (3) Greater freedom in both official and non-official activities; (4) Just and reasonable salaries based on service performed and the economic and social conditions which prevail; (5) Greater public recognition of the aims and purposes of research; (6) Advancement of science and technology as an essential element of national life.

Three plans of organization were offered to the meeting, which covered the fundamental principles which could be utilized by these Government employees. The first plan would have permitted the new organization to work only through existing scientific organizations. This is the plan that scientific and technical government employees in England have adopted and an outline of the English plan was read to the meeting. An independent organization of federal employees doing scientific and technical work was also proposed and a third plan, which was finally adopted by the meeting, provided for the forming of a scientific and technical branch of the Federal Employees' Union. This was upheld principally by Dr. Rosa of the Bureau of Standards. He pointed out the unfavorable conditions under which scientists working for the Government had to solve big problems, and that this, the richest nation, can afford the best scientific service. The present service is fast drifting from efficient channels because of the loss of their best personnel.

His principal reason for recommending the affiliation with the Federal Employees' Union at once was because of the going organization and the prestige that it had already established.

This is an important step forward for the scientific and technical Government employees because it is contemplated that it will lead to important reforms in classification and compensation. It is closely connected with the work that Engineering Council has aimed to accomplish through its committee on Classification and Compensation of Engineers, and it is contemplated that Council will be able to give effective coöperation in the work of classification that must be inaugurated.

Plans for Training of the Commercial Engineer

The Commissioner of Education has issued a call for a public conference on business training for engineers and engineering training for students of business. This conference, national in scope and character fully representative of all interests, will be held in Washington, D. C., on June 23 and 24.

This conference has been called on behalf of the Conference Committee on Commercial Engineering, which is composed of administrative professors in engineering and commerce from several of the large educational institutions and representatives, from the Society for the Promotion of Engineering Education, the American Society of Civil Engineers, The American Society of Mechanical Engineers, American Institute of Mining and Metallurgical Engineers, American Institute of Electrical Engineers and a Committee of Fifteen on Educational Preparation for Foreign Service. The major topics to be discussed are Business Training for the Engineer; Engineering Training for Commercial Enterprises; Significance of the War Experience for Engineering Education; and Training of the Engineer for Foreign Projects.

Plans for Railroad Control

Many interesting plans covering the ownership, operation and control of railroads have been shown in Washington. It is always interesting to the engineer to note the position of the various organizations directly connected with this work, because all branches of the profession are intimately related to the vicissitudes of the railroads.

On the one side generally stands labor and on the other side stand all the other interested parties. This is the case with the railroads. The railway executives, railroad security owners, Interstate Commerce Commission, Director General of Railroads and numerous individual financiers and railroad men all stand for private ownership and operation of the railroads because they believe that efficient operation can be had in no other way. The railways brotherhoods on the other hand stand for Government ownership and they want the operation of the roads to be by private corporation, run by employees and paying Government rental out of the receipts of operation.

Government ownership and operatives' management of railroads is summed up in what is known as the "Plumb Plan." Mr Glenn E. Plumb is attorney for the "Big Four Railroad Brotherhood" and the ten brotherhoods affiliated with the American Con

federation of Labor. He has just arrived in Washington to care for the interests of this plan. He announced that it is to be incorporated in the form of necessary bills for legislative action which will be introduced at the approaching special session of Congress. Mr. Plumb expects the railroad problem to develop into a presidential campaign issue and contemplates that the railroad question will have to be "put up to the people direct." Mr. Plumb says, "If these demands (for rate decreases) were fully met, any deficiency must be made by wage reduction." His own words perhaps best explained his reason for coming to the national capital.

The brotherhoods' plan for the control of the railroads provides that there will be no "Secretary of Transportation" but there will be continuation of powers of Interstate Commerce Commission. The directors shall be elected, one-third by non-appointed employees, one-third by appointed officers and employees, and one-third by the President.

The railway executives recommend that a cabinet officer, to be known as "Secretary of Transportation," be appointed. They say that the Interstate Commerce Commission should be relieved of the executive and administrative duties, except as to the valuation and accounting, and they are to act as a quasi-judicial body with regional commissions.

Railway security owners recommend federal regulation through the Interstate Commerce Commission, as at present constituted, and coördinating with six regional commissions, who in turn will coördinate with the state officials.

The present Interstate Commerce Commission wants a better defined relationship between state and federal control, with a broadening of federal control.

The Director General, as is commonly known, stands for five-year extension of federal control with modified private operation and control thereafter. This plan provides for Government representation on boards of directors.

NATIONAL RESEARCH COUNCIL

Dr. George E. Hale Resigns as Chairman and Dr. James R. Angell is Appointed as His Successor. New York Office of the Council Opens in the Engineering Societies Building

In the last number of Mechanical Engineering reference was made (p. 485) to the recent organization of the National Research Council of the National Academy of Sciences on a peacetime basis, and to the pioneer work which its distinguished chairman, Dr. George E. Hale, Director of Mt. Wilson Observatory, had done in coördinating and directing its activities.

Announcement has been made that Dr. George E. Hale will hereafter be the Honorary Chairman of the National Research Council and Dr. James R. Angell, ex-president of the University of Chicago Settlement and member of the American Psychological Association, who so eminently served the Nation on the committee of the Adjutant General's office on classification of personnel in the Army and as advisory member of the committee on education and special training, will replace Dr. Hale in the executive direction of the Council.

The chairmen of divisions of the National Research Council have been appointed as follows:

Division of Physical Sciences. Chairman, C. E. Mendenhall; acting chairman until June 30, A. O. Leuschner.

Division of Engineering. Chairman, Henry M. Howe; vice-chairman and acting chairman, Galen H. Clevenger.

Division of Chemistry and Chemical Technology. Acting chairman until June 30, E. W. Washburn; chairman, July 1, 1919, to June 30, 1920, W. D. Bancroft; vice-chairman, Julius Stieglitz.

Division of Geology and Geography. Vice-chairman and acting chairman, E. B. Mathews.

Division of Biology and Agriculture. Chairman, C. E. McClung; vice-chairman, L. R. Jones.

In these divisions there are representatives of the various leading societies associated in the particular work covered by the divisions. In the Engineering Division the societies represented are the Civil, Mining, Mechanical and Electrical, Illuminating and Automotive Engineers, the Society for Testing Materials and Western Society of Engineers. The representatives from The American Society of Mechanical Engineers are Arthur M. Greene, Jr., Chairman of the Research Committee of the Society, and Past-Presidents W. F. M. Goss and D. S. Jacobus, the two latter being members of the Engineering Foundation.

According to a note in *Science,* May 16, 1919, the National Research Council has announced the following initial appointments to national research fellowships in physics and chemistry:

In Chemistry. F. R. Bichowsky, of Washington, D. C., A.B., Ph.D., physical chemist at the geophysical laboratory of the Carnegie Institute of Washington since 1916; Mr. Bichowsky plans to conduct researches at the University of California. Emmett K. Carver, of New York City, A.B., Ph.D., formerly assistant to the director of the Wolcott Gibbs Memorial Laboratory at Harvard, Captain, Chemical Warfare Service, U. S. S. A. W. H. Rodebush, Ph.D., present research chemist for the United States Industrial Alcohol Company, of Baltimore, Md.; Mr. Rodebush will conduct researches at the University of California on a Study of the Specific Heats and Other Properties of Substances at Low Temperatures.

In Physics. Leonard B. Loeb, of New York City, B.S., Ph.D., formerly assistant physicist at the Bureau of Standards, Washington, D. C., Lieutenant, Aviation Service, U. S. A.; Mr. Loeb will conduct his researches at the University of Chicago. Robert A. Patterson, of Bristol, Conn., A.B., Ph.D., formerly instructor in physics at Yale University, Major, Field Artillery, U. S. A. George P. Paine, of Madison, Wis., A.B., Ph.D., instructor in engineering mathematics University of Wisconsin; Mr. Paine will conduct research work at Harvard University and at Blue Hill Meteorological Observatory.

Another important development which no doubt will bring about practical results of value to the engineering profession is the recent affiliation of the Engineering Foundation with the National Research Council. To contribute to the mutual collaboration of the two institutions, office space in the Engineering Societies Building has been provided by the Engineering Foundation to serve as the New York Office of the Engineering Division of the National Research Council, and the Foundation, having brought its office to the adjacent room, in addition proffers to the Council and its Engineering Division such secretarial services as the Foundation may from time to time determine.

The office of the Engineering Division of the National Research Council was opened on June 1, and is now operating under the direction of Galen H. Clevenger, acting chairman of the division. The National Research Council proposed that its Engineering Division, comprising in all not less than 23 or more than 28 members, of whom at least 7 and not more than 12 shall be members at large, be so organized as to include at least 5 members of the Engineering Foundation, and, including these 5, 17 members of the Founder Societies; this proposal was accepted by the Engineering Foundation as well calculated to meet the mutual requirements of the Foundation and the Council. It is the purpose of the Engineering Foundation to collaborate with the National Research Council in the activities of its Engineering Division and to make such appropriations to aid its specific undertakings as the Foundation may from time to time determine.

Patents originating in Government service or patents which may be turned over to the Government by private inventors who are not able to develop their inventions commercially are to be administered by the Department of Commerce if the proposed bill for this purpose is passed by the next Congress.

NEWS OF THE ENGINEERING SOCIETIES

Report of Annual Meetings of Electrical Engineers, American Institute of Architects, National Metal Trades Association, United States Chamber of Commerce, etc.

Institute of Radio Engineers

At its meeting of May 7, held in the Engineering Societies Building at New York, the Institute of Radio Engineers presented to Mr. E. F. W. Alexanderson, of the General Electric Company, a gold medal in recognition of his achievements in the field of radio communication. The wireless telephone, declared Mr. Alexanderson in his remarks following the presentation of the medal, was the result of an attempt to transmit power without wires. The possibilities of the wireless telephone having once been conceived, however, experiment and research soon developed it so that today it is an accepted fact.

American Institute of Electrical Engineers

At the annual business meeting of The American Institute of Electrical Engineers, held in New York on May 16, the presentation of the Edison Medal for meritorious achievement in electrical science or electrical engineering took place, it being awarded this year to Benjamin G. Lamme, of the Westinghouse Electric and Manufacturing Company. The presentation was made by William B. Jackson, Vice-President of the Society.

The award was made to Mr. Lamme for inventions and developments of electrical machinery. During the war he served as a member of the Naval Consulting Board, to which he was appointed on the recommendation of the institute. Mr. Lamme has taken out more than a hundred patents for electrical devices, appliances, and systems now in general use.

The society recently held its annual election and announcement was made of the election of Calvert Townley of New York as president and of the reëlection of F. L. Hutchinson as secretary for the administrative year, beginning August 1, 1919. Mr. Townley is assistant to the president of the Westinghouse Electric and Manufacturing Company. He served as an active official of the New York, New Haven and Hartford Railroad in connection with the electrification of the New York terminal zone of that property and is an authority on electrification.

National Machine Tool Builders' Association

The need of continued close attention to production costs and their relation to selling prices and the disposal of the machine tools which the United States Government has on its hands both here and in Europe were the leading topics before the Spring meeting of the National Machine Tool Builders' Association at Atlantic City, May 12-13.

Colonel Guy Hutchinson, assistant director of sales, War Department, expressed appreciation for the part which the machine-tool industry had played in the war. It was production more than man power, the speaker said, that determined the issue of the war. He regretted that production had not got an earlier start, saying that the small quantity of munitions which the United States got to the front before the crucial time arrived had cost a large number of the lives of our allies. The big mistake made, he asserted, consisted of turning factories into playgrounds for engineers for about one year.

The Committee on Safety Codes reported that the Bureau of Standards at Washington was calling for nation-wide regulation of safety provisions, and that two plans had been suggested. Under one of these the Bureau of Standards would draw up general regulations which were then to be adopted by the states, and under the other the work of securing uniformity would be undertaken by the American Engineering Standards Committee made up of members of the national engineering societies.

In his address President A. E. Newton foresaw a keen competition in the near future between manufacturers of machine tools. He warned against what he termed the fallacies of an erroneous study of cost-accounting systems. He advised that in reducing prices it was not sufficient to consult the cost as shown by the individual machines, but also to take into account the real cost as shown by the annual statement. A full report of the meeting is contained in the *Iron Age* for May 15, 1919, from which the foregoing notes were taken.

American Institute of Architects

A prominent feature of the fifty-second annual convention of the American Institute of Architects, held at Nashville, Tenn., April 30, May 1 and 2, was the discussion of the principles set forth in the program of the Post-War Committee on Architectural Practice. The debate on the various topics taken up was a serious and thoughtful consideration of the elements of architectural practice that are now considered of vital significance in the reorganization of the profession. Preliminary to the discussion, John Bell Keeble, member of the bar of the state of Tennessee, spoke on the Relationship of the Professions.

In his address on Professional Principles, President Thomas R. Kimball pointed out the part professionalism should play in developing adequate relations between architects, the public and the other professions. He condemned the practice, as he termed it, among professional men of indulging in tales of discomfiture to and of each other and before audiences inclined to be more interested than discerning, and expressed his belief that through professionalism as a common factor architects may reach an interprofessional understanding based on the common factor of giving skilled service to others.

N. Max Dunning, chairman of the Post-War Committee, stated that in his opinion two important things had been emphasized by our war experience: the value and necessity of organization, and the proper appreciation of the value and nobility of service.

National Foreign Trade Convention

Necessity for an expanded foreign trade in stabilizing domestic conditions was emphasized and the vital factors wherein this country is at a present disadvantage in overseas commerce were set forth by the National Foreign Trade Council in summing up the deliberations of its sixth convention at Chicago, April 24-26, which was dedicated to the theme, Foreign Trade Essential to the American Industry. A forward-looking recommendation was that congressional consideration be given to suitable plans for developing aerial navigation, and it was declared that the promotion of airship service to overseas countries demands the establishment of a separate government department. It was suggested that local chambers of commerce entertain the advisability of having public aerodromes in all centers which expect to develop large foreign markets in order that prompt delivery of plans and specifications, blueprints and invoices may be made from seaports to the interior. Throughout the convention stress was laid upon the fundamental rule that if this country is to have an enlarged export trade it must also be prepared and should expect to receive a greatly expanded volume of imports. Enduring foreign trade, it was stated, must be reciprocated.

National Metal Trades Association

That 86 per cent of the metal-working establishments of the country have a working schedule of 50 or more hours per week,

was brought out at the annual meeting of the National Metal Trades Association, held at New York, April 23-24. Less than 10 per cent of the members of the association have an 8-hour basic day, and few have an actual 8-hour working day. The opinion prevailed that nothing further should be done at this time to reduce hours of labor or to take other action affecting the length of the working day while present conditions prevail.

J. W. O'Leary in his presidential address foreshadowed the formation of a National Peace Labor Board similar to the National War Labor Board during the war. Referring to the activities of the National Industrial Conference Board he said that the presidents of 23 national industrial associations meet monthly and discuss the general problems of industry. Secretary of Commerce William C. Redfield urged the members of the association and business men generally to avail themselves of the resources of the Department of Commerce, the scientific organization of which employs 1200 scientists and occupies nine buildings with 24 acres of floor space.

United States Chamber of Commerce

Stimulation of domestic and foreign trade by federal enactments, speedy termination of river improvement projects already authorized and provision by Congress for a comprehensive system of waterways with coördination of the services of waterways and railways, prompt return of the railroads to their owners and immediate resumption of construction activities was the import of resolutions adopted by the Chamber of Commerce of the United States in its seventh annual convention at St. Louis, Mo., April 28 to May 1.

While the business men of the country pledged themselves to whole-hearted coöperation with the Government, they declared that the final responsibility before the country in the matter of readjustment rested with the federal authorities. The suggestion was made to consider the revision of all federal laws dealing with business conditions to the end that by proper readjustment of their provisions and of the functions of federal agencies, industry and commerce in the United States may clearly know at all times their powers, rights, limitations and obligations.

It was notable that Director General of Railroads Walker D. Hines and Secretary of Commerce Redfield expressed themselves in accord with some of the most vital principles advocated by the chamber. Mr. Hines recommended the return of the railroads, as did Senator A. B. Cummins, another speaker, while Mr. Redfield favored the abolishment of old-time restrictions on trade and the keener coöperation of the Government with private industrial enterprise.

Chairman Edward N. Hurley of the United States Shipping Board took a most hopeful view of the outlook of the American ship industry. He called attention to the excellent opportunity this country has now to establish on a solid footing the merchant marine which it wants and needs, and felt confident that Congress would pass legislation which would be helpful in accomplishing a permanent and efficient American merchant marine.

American Gear Manufacturers' Association

Standardization of gears was the predominant question of the American Gear Manufacturers' Association at their annual convention in Cleveland, April 14-16. The standardization committee reported that while their work could not be considered as yet in its final form, still the investigations which the committee has performed would eventually lead to remarkable results in obtaining a better standard for gear users and gear manufacturers. The standardization of inspection was also extensively discussed, and it was expected that uniform practice would soon be established, particularly in regard to complaints by users of gears for claims which are in no way the fault of the gear manufacturer.

The composition and physical characteristics of steels for gear making, as well as suggestions in heat treating in this connection, were given in a paper on Gear Steels by J. Herber Parker. Tempered gears have been criticized on account of pitting of tooth surfaces, which was found after limited service. Mr. Parker mentioned several experiences where the condition of pitted surfaces was corrected by reducing the unit tooth pressure. The following are of particular interest:

(1) Misalignment of gears was believed to be the cause of the trouble, thus throwing an excessive load upon only a part of the tooth and vastly increasing the unit tooth pressure. When the gears were properly adjusted and the load properly distributed, pitting disappeared.

(2) A little lower drawing temperature after hardening, which resulted in an increase of about five points in scleroscope hardness, eliminated pitting. The slight increase in hardness was sufficient to enable the gear tooth to withstand the unit tooth pressure put upon it.

(3) Pitting was eliminated by increasing the length of the tooth face. This increase resulted in decreasing the unit tooth pressure to a safe figure. Properly case-hardened gears which have a scleroscope hardness of about 90 will undoubtedly withstand, without pitting, unit tooth pressures which will give trouble in the case of a tempered steel gear which is about 75 scleroscope hard.

Other technical papers presented before the convention were: Worms and Worm Wheels, by G. W. Carlson, and Proper Sizes and Materials for Gears for Tractor Construction, by E. J. Frost.

Air Brake Association

Results of tests and numerous opinions as to the cause of excessive leakage in the auxiliary devices of the locomotive air-brake system and the method that should be used to overcome it were presented at the twenty-sixth annual convention of the Air Brake Association, held at Chicago May 6 to 8.

The Committee on Air Consumption of Locomotive Auxiliary Devices entrusted with this investigation performed both standing and running tests. The standing tests were made on locomotives in roundhouses, and consisted in measuring the amount of air used by the auxiliary devices operated while the locomotives were standing. The running tests were made on freight engines working over the road in service, and consisted of the continuous measurement of air used by the auxiliary devices in operation while the engine was running. A total of 489 individual tests were classified and arranged in the report submitted by the committee. A summary of their principal results is as follows:

1 Auxiliary devices under average conditions were found to use too much air.

2 Conditions frequently exist where compressor capacity may be exceeded by the demands of the auxiliary devices.

3 Some of the data justify the conclusion that auxiliary devices should be operated separately from the air-brake system. On the other hand, some of the data show that with proper maintenance this conclusion might not be warranted.

4 Under some conditions it would not be satisfactory to connect the auxiliary devices to the air-brake system and increase the compressor capacity accordingly, unless the air-brake main reservoir were protected from the consequences of excessive air requirement by the auxiliary devices.

5 Cost-basis data show that better maintenance would be profitable.

6 Standards of performance, including maximum permissible leakage, should be established.

7 Means should be devised for checking and testing the performance of auxiliary devices.

The committee did not consider their work as complete and recommended that their data be further increased by investigations on individual railroads. They concluded by advocating the plan of operating the auxiliary devices at a pressure lower than that carried in the air-brake system main reservoir. This plan would effect a large saving in air used, but would require a separate air-supply reservoir with means provided for controlling the reduced pressure.

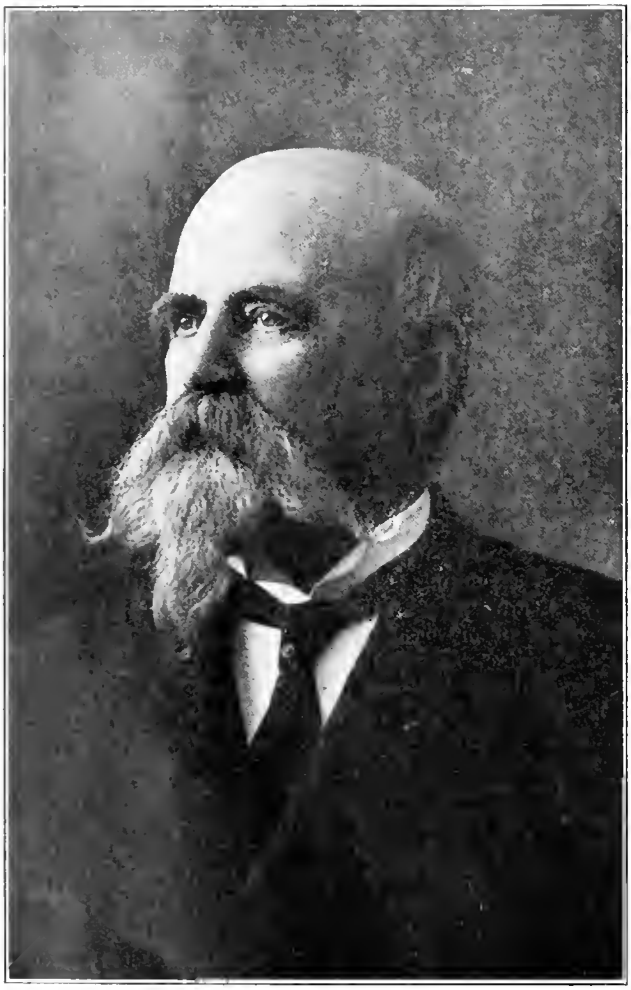
An American Petroleum Institute has been formed with its headquarters in Washington. Its function will be to promote mutual coöperation between representatives of the industry and the departmental or legislative organizations of the Government.

NECROLOGY

CHARLES H. MANNING

Captain Charles H. Manning, honorary member of the Society and for many years prominent in engineering circles in New England, died at Manchester, N. H., on April 1. Captain Manning was born in Baltimore, Md., on June 9, 1844, and received his early education in that city and in Cambridge, Mass., later entering the Lawrence Scientific School of Harvard University, from which he was graduated in 1862 with the degree of B. S.

In February 1863 he was appointed third assistant engineer of the



Charles H. Manning

Navy. His knowledge and comprehensive grasp of scientific matters brought him to the attention of Chief Engineer Isherwood, who assigned him to the making of experiments on superheating steam on the U. S. S. *Adelaide*. He served on the *Adelaide* for two years, when he left her to join the sloop-of-war *Dacotah*. In 1870 Captain Manning was assigned to shore duty as an instructor in the Naval Academy where he remained five years. During this period he assisted in organizing a course of instruction for cadet engineers at the Academy, and this is considered one of his most valuable achievements.

Captain Manning also served as a member of the first Advisory Board that prescribed the specifications for the so-called "New Navy." Other members of the Board were Rear-Admiral John Rogers and Chief Engineers Benjamin F. Isherwood and Charles H. Loring.

In 1882 Captain Manning retired from active duty in the Navy and was not called into active service again until the Spanish-American War, when he was stationed at the Naval Station at Key West as chief engineer of the repair of the machinery of warships which gathered there. He was commissioned chief engineer on the retired list in February, 1911.

In 1883 Captain Manning became associated as chief engineer with the Amoskeag Manufacturing Company, Manchester, N. H., the largest cotton mills in the world. He had charge of all their power plants and saw the steam power plant grow from one with 870 sq. ft. of grate surface and burning about 400 tons per week, to one with 5,800 sq. ft. of grate surface and capable of burning some 3,000 tons of fuel per week.

The resourcefulness of Captain Manning is well typified by the following incident: In the fall of 1891 a 30-ft. flywheel burst, and being dissatisfied with the metal put into flywheel rims at the time, he designed a new wooden-rimmed wheel of the same diameter with a face of 108 1-4 in. and a thickness of 12 in. This rim was made up of forty rings of ash, and was doubtless the largest wooden-rim wheel in the world.

In addition to his position with the Amoskeag Company, Captain Manning acted as consulting engineer for several other large mills. He was the designer of the well-known Manning boiler and was associated with many pioneer power-plant designs, including one of a 200-hp. horizontal water turbine which at the time of its installation in 1885 was the largest of its kind.

In 1913 Captain Manning retired from the Amoskeag Company and opened offices as a consulting engineer.

As a resident of Manchester, Captain Manning was a very useful citizen. For 28 years he was a member of the Board of Water Commissioners—most of the time its president, and during his incumbency the system was greatly extended and improved. For 18 years he was a member of the school board, where his advice was much respected.

Captain Manning became a member of the Society in 1884 and was made an honorary member in 1913. From 1893 to 1895 he served as manager and from 1895 to 1897 as vice-president of the Society. He was also a member of the Army and Navy Club of New York, the American Society of Naval Engineers, the United States Naval Institute, the American Society of Naval Architects and Marine Engineers, the American Association for the Advancement of Science and the American Association of Cotton Manufacturers.

HARRY H. COOK

Harry H. Cook, chief engineer of the Chapman Valve Manufacturing Co., Indian Orchard, Mass., died on December 15, 1918. Mr. Cook was a 1906 graduate of the Massachusetts Institute of Technology. He was formerly connected with the Coffin Valve Company as chief engineer and with the Providence Engineering Works as sales engineer. Mr. Cook became a junior member of the Society in 1910 and was promoted to full membership in 1918.

JOSEPH FRANZ DIEPENBROCK

Joseph F. Diepenbrock, who until five months ago was in the employ of the Arnold Engineering Co. on important work in connection with Fort Sheridan, died on April 7, 1919. Mr. Diepenbrock was born in Germany on August 28, 1874. He was educated in Essen, attended the Fachschule at Hagen and was graduated from the College Charlottenburg.

He came to the United States in 1901 and became associated with the Dickson Manufacturing Co., Scranton, Pa. From 1902 to 1910 he was employed by the Allis-Chalmers Co., when he resigned to accept a position with the H. R. Worthington Co. He was with the Arnold Engineering Company when his health failed and he was forced to give up active work. Mr. Diepenbrock became a member of the Society in 1912.

MARSHALL TENBROECK DAVIDSON

Marshall T. Davidson, president of the M. T. Davidson Co., Brooklyn, N. Y., died on April 10, 1919. Mr. Davidson was born on February 17, 1837, in Albany, N. Y. He was graduated from the Albany Academy and Polytechnic Institute. During the Civil War he served in the Navy as second assistant engineer and later was promoted to the position of chief engineer in the Revenue Cutter service where he superintended the construction and installation of machinery on vessels for this department. At the close of the War Mr. Davidson engaged in the contracting business and later established the company of which he was president for the construction of the Davidson steam pumps, pumping engines, condensers, evaporators, etc. He was a member of the Society of Naval Architects and Marine Engineers, the Naval Order of the United States and a life member of the Navy League. He became a member of our Society in 1886.

JOSEPH ESREY JOHNSON, JR.

Joseph E. Johnson, Jr., consulting engineer and metallurgist, New York City, died on April 4, 1919. Mr. Johnson was an 1888 graduate of Haverford College, Pa., and received his master's degree in mechanical engineering from Cornell University in 1892.

Mr. Johnson was first employed in the drafting room of the Baldwin Locomotive Works, where he was located for about two years. In 1893 he entered the employ of John E. Sweet of the Straight Line Engine Co. He was next connected with the Solvay Process Co. and in 1894 became assistant to the president of the Ames Iron Co., Oswego, N. Y. In 1895 he became associated with the Longdale Iron Co. as engineer and assistant manager. From 1899 to 1901 he was with the Carnegie Steel Co. when he again returned to the Longdale Iron Co., remaining there until 1906 when he became general manager

of the Princess Furnace Co., Glen Wilton, Va. In 1909 Mr. Johnson was appointed general superintendent of the furnaces and coke ovens of the Republican Iron & Steel Co., Birmingham, Ala., and the following year he became manager of the blast furnace and chemical plant of the Lake Superior Iron & Chemical Co., Ashland, Wis. In 1913 he opened consulting offices in New York City.

Mr. Johnson was a director of the American Institute of Mining and Metallurgical Engineers, member of the American Electrochemical Society, the American Iron and Steel Institute, the British Iron and Steel Institute, the American Institute of Weights and Measures and the American Society for Testing Materials. He became a member of our Society in 1896.

WILLIAM D. KELLEY

William D. Kelley, general superintendent of meters of the Consolidated Gas Company of New York, died on April 12, 1919, at his home in Mount Vernon, N. Y. Mr. Kelley was identified with the gas industry in New York City for forty-one years. He began this business career as a "fitter" but developed rare business qualifications and received frequent advancements so that at the time of his death Mr. Kelley was considered one of the most efficient men in the gas industry.

Mr. Kelley was educated in the public schools of New York City. At the time of his death he was a member of the American Gas Association, the Society of Gas Engineering of New York City and the National Association of Corporation Schools. He became a member of our Society in 1915. Mr. Kelley took a very active part in the proceedings of these organizations and was greatly interested in their work.

His funeral was held on April 15 at Mount Vernon, N. Y., and was attended by many officials and employes of the Consolidated Gas Company of New York.

EDWARD BYRON McKINNEY

Edward B. McKinney, who until his retirement in 1917 was superintendent of power of the New Orleans Railway & Light Co., died on March 30, 1919. Mr. McKinney was born in New York on February 14, 1854, and was educated in the city schools. He served his apprenticeship with the Delamater Iron Works, New York, and afterward served as assistant and later as chief engineer on ocean-going steamers. From 1889 to 1895 he was chief engineer of the Louisiana Electric Light Co., New Orleans, later holding similar positions with the St. Charles St. Railroad Co. and the New Orleans Traction Co. In 1905 he was appointed to the position of superintendent of power of the New Orleans Railway & Light Co. Mr. McKinney became a member of the Society in 1907.

FREDERICK LEO NEELY

Frederick L. Neely, who was engaged on important development work for the E. I. du Pont de Nemours Co., died on January 5, 1919, of influenza. Mr. Neely was born on January 1, 1883, in St. Petersburg, Pa., and was graduated from the Pennsylvania State College in 1904. For five years he was associated with the Allis-Chalmers Co. as superintendent of their erection department and in connection with their sales work. He was also connected for a few years with the Macon Railway & Lighting Co., as superintendent of the public utilities plants of the company. His work with the du Pont Company dealt in great part with the mechanical, experimental and development work on smokeless powder. Mr. Neely became a junior member of the Society in 1909 and was promoted to full membership in 1914.

CHARLES B. RICHARDS

Charles Brinckerhoff Richards, Higgin professor of mechanical engineering in the Sheffield Scientific School, Yale University, for a quarter of a century and since 1909 professor emeritus, died at his home in New Haven, Conn., on Sunday, April 20, 1919, in his eighty-sixth year. Professor Richards was born in Brooklyn on December 23, 1833, and was educated in private schools in that vicinity.

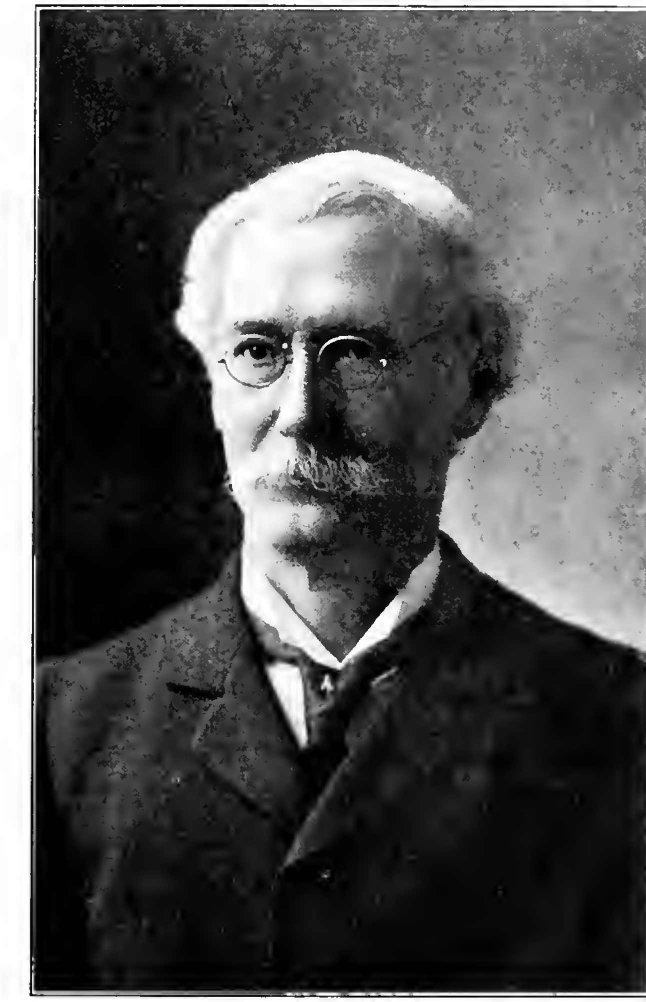
In an article for the *Yale Daily News* Professor Lockwood of Sheffield writes:

"In the death of Professor Charles B. Richards, the mechanical engineering profession loses one of its most prominent members. His early life was spent in Hartford, Conn., at a period when engineering colleges were unknown. He was obliged, therefore, to acquire his theoretical education by the power of personal application, of broad reading and diligent study—this all carried on while busily engaged in practical daily work along manufacturing lines.

"His school was the famous Colt's Armory where his mechanical genius was early recognized. At the age of twenty-seven he opened an office in New York as consulting engineer and at once leaped into wide prominence by his invention of the steam-engine indicator, which made the name of Richards a familiar one wherever steam engines were used. This instrument was produced at a time when the high-speed engine was in its infancy and aided greatly in its development. For this achievement he was made a Chevalier of the Legion of Honor of France, as well as receiving medals from the London Exposition of 1862, the American Institute in 1869, and the French Exposition in 1878.

"With the outbreak of the Civil War Mr. Richards was recalled to Colt's as their assistant superintendent and consulting engineer, where he spent nineteen years of active life. He developed the platform-scale testing machine for testing the strength of metals and was also an authority on the heating and ventilation of buildings, acting as consulting engineer for several large projects, among them the Capitol at Hartford and several of the Yale University buildings. His fertile mind was constantly at work on inventive problems. He was deeply interested in the microscope and made several improvements for which he was granted patents.

"In 1880 Mr. Richards became superintendent of the Southwark Foundry and Machine Company in Philadelphia, manufacturers of the



Charles B. Richards

Porter-Allen high-speed engine, marine and other large machinery. Four years later he was invited to become professor of mechanical engineering at the Sheffield Scientific School of Yale University and entered upon the new work of teaching. An inborn taste for study and research undoubtedly led to this choice. For twenty-five years Professor Richards served as the head of the mechanical engineering department, where successive classes were inspired by his friendly spirit and high ideals.

"He was engaged in occasional activities in addition to teaching. He was an American Commissioner at the Paris Exposition in 1889, and edited the report of mechanical appliances. As associate editor he was responsible for the technical terms in two editions of Webster's New International Dictionary.

"In 1909 at the age of seventy-five Professor Richards retired from active work. The esteem of his classes was expressed on this occasion by their presentation to the school of an oil portrait of Professor Richards. This portrait now hangs in the faculty room of the Sheffield Scientific School.

"Professor Richards was a stern disciplinarian and believed in the doctrine of work. Yet his friendly interest in the individual student and his enthusiasm for engineering aroused and maintained a helpful spirit of coöperation with his classes while his great ability and wide experience were recognized and admired."

Professor Richards was a member of the Société Industrielle de

Mulhouse, Alsace, the Society of Naval Architects and Marine Engineers, the Connecticut Academy of Sciences, and a Fellow of the American Academy of Arts and Sciences. He was a charter member of our Society, being present at the organization meeting on April 7, 1880.

DAVID BRAINERD OVIATT

David B. Oviatt, assistant engineer, Board of Water Supply, New York City, died on February 12, 1919. Mr. Oviatt was born in Salem, N. Y., on May 20, 1858. He was graduated from Cornell University in 1887 with the degree of M. E. He was at one time connected with the American Bridge Co., Trenton, N. J., and with the New York Rapid Transit Railroad Co. For several years he also held the position of steel inspector for the New York & Long Island Railroad Co. Mr. Oviatt was appointed to the Board of Water Supply in 1909. He became a member of the Society in 1891.

CARL A. STROM

Carl A. Strom, manager of the Cooke Works of the American Locomotive Co., at Paterson, N. J., died in New York, on March 26, 1919. Mr. Strom was born on August 22, 1868, in Motala, Sweden, and was graduated from the Royal Polytechnic Institute, Stockholm, Sweden, in 1889. He was formerly connected with the Chicago, Omaha and Southwestern Railroad and the Illinois Central. He was also chief mechanical engineer with the Isthmian Canal Commission on the construction of the Panama Canal. Mr. Strom became a member of the Society in 1905.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by June 15 in order to appear in the July issue.

CHANGES OF POSITION

R. L. Thomsen has become associated with the Terry Steam Turbine Company, Hartford, Conn., in the capacity of sales manager. Mr. Thomsen was previously connected with the Griscom-Russell Company, New York, as manager of the marine department.

Arthur C. Lindholm, formerly affiliated with the Colt's Patent Fire Arms Company, Hartford, Conn., as mechanical engineer, has assumed the position of general manager of the Franklin Machine and Tool Company, Springfield, Mass.

Raymond A. Cole has become connected with the engineering department of the Norton Grinding Company, Worcester, Mass. He was, until recently, engineer in the machine gun department of the Colt's Patent Fire Arms Company, Hartford, Conn.

L. W. Helmreich, formerly engineer, Electricity, Gas, Heat and Water Department of the Public Service Commission of Missouri, Jefferson City, Mo., has accepted the position of chief engineer of the Corporation Commission of the State of Arkansas.

Lester B. Paterson has resigned his position as scheduling engineer and shop accountant, Readville Shops, N. Y., N. H. and H. R. R. Company, and has accepted the position of planning engineer of The Carrie Gyroscopic Corporation, New York.

W. F. Rockwell, vice-president in charge of engineering and manufacturing with the Torbensen Axle Company, Cleveland, Ohio, has resigned, effective May 1, to become general manager of The E. B. Hayes Machinery Corporation at Oshkosh, Wis.

Edward P. Warner, formerly aero engineer, Bureau of Aircraft Production, U.S.A., Massachusetts Institute of Technology, Cambridge, Mass., is now employed as chief physicist by the National Advisory Committee for Aeronautics, Research Laboratory, Langley Field, Hampton, Va.

Henry B. Dirks, formerly assistant professor of civil engineering, Princeton University, Princeton, N. J., has accepted the position of professor of mechanical engineering, Michigan Agricultural College, East Lansing, Mich.

Adolf Aeberli has severed his connection with the Canadian Allis-Chalmers Company, Ltd., Toronto, Ont., Canada, and has become associated with the Hydro-Electric Power Commission of Ontario, Toronto, Canada.

Arthur F. Worden, until recently connected with the DuPont Engineering Company, Jacksonville, Tenn., in the capacity of fire protection engineer, has entered the service of the American District Telegraph Company, New York, as plant engineer.

J. G. Berger has become associated with L. K. Comstock and Company, which has recently established a Newark office under the direction of Mr. Berger. This office will engage in the sale of complete industrial and power equipments, as well as construction service. Mr. Berger was formerly connected with the William Gordon Corporation, Philadelphia, Pa., in the capacity of chief engineer.

Norbert S. Atwell, formerly in the employ of the Bureau of Aircraft Production, New York, has entered the engineering department of the United States Ball Bearing Manufacturing Company, Chicago, Ill.

Harold Prigoff, until recently assistant works engineer, Savage Arms Corporation, Utica, N. Y., has become associated with the machinery sales department of the Syracuse Supply Company, Syracuse, N. Y.

S. L. Simmering has resigned his position as research associate in the engineering experiment station, University of Illinois, to accept a position as assistant professor of mechanical engineering in the University of Colorado, Boulder, Colo.

Walter H. Hall has accepted the position of plant engineer, Champion Ignition Company, Flint, Mich. He was formerly connected with the Remington Arms Union Metallic Cartridge Company, Swanton, Vt., in the capacity of works engineer.

ANNOUNCEMENTS

Lieut. C. W. Nickerson, U.S.N.R.F., was relieved of all active duty on April 19 and is now associated as mechanical engineer with the North American Dye Corporation, Mt. Vernon, N. Y., manufacturers of Sunset soap dyes.

Alvan L. Grout has assumed the duties of plant engineer of the Saco Lowell Shops, Biddeford, Me.

Harry J. Angell, formerly 2d Lieutenant, 26th Engineers, 1st Army Water Supply Service, has returned to the Goulds Manufacturing Company, of New York, in the capacity of sales engineer.

John F. Vaughan has resumed his engineering practice. His resignation as district manager for the Emergency Fleet Corporation (New England district) was accepted, to take effect May 1.

Dr. William P. Gerhard was recently asked by the United States Housing Corporation to serve on a committee composed of four engineers, to investigate and list the plumbing work in several groups of buildings of the Corporation at Bridgeport, Conn.

James L. Myers, Lieutenant Army Ordnance, Engineering Division, Motor Equipment Section, Washington, D. C., has received his discharge and is now connected with the Cleveland Graphite Bronze Company, Cleveland, Ohio, in the capacity of sales engineer.

Clarence Boyle, Jr., secretary of Clarence Boyle, Inc., Chicago, Ill., and formerly district sales manager of the Taylor-Wharton Iron and Steel Company, is changing his residence from Chicago, where the main office of the former company is located, to Atlantic Beach, Fla., to manage the Florida interests of his company.

A. L. Menzin, industrial engineer, has moved his office from Philadelphia, Pa., to San Francisco, Cal., in which city he was formerly located.

Francis D. Ammen, for a time identified with the Emergency Fleet Corporation, St. Louis, as production assistant, has formed a partnership with Bruce S. Elliott, for the practice of patent trade-mark and copyright law. They will practice under the firm name of Elliott and Ammen, with offices in St. Louis, Mo.

Henry C. Meyer, Jr., William E. S. Strong and Bassett Jones announce the formation of the firm of Meyer, Strong and Jones, Inc., which will conduct an engineering office for reporting upon and designing power plants and the mechanical and electrical equipment of buildings and industrial establishments. Offices of the firm are at 101 Park Avenue, New York.

Ronald K. MacMaster, who has served as 1st Lieutenant, Ordnance Department, U.S.R., Gun Division, Production Section, has been promoted to the rank of Captain.

Max Toltz announces the association of Beaver Wade Day, architect, with the Toltz Engineering Company, the name of the company being changed to Toltz, King and Day, Inc., engineers and architects. In addition to the consulting engineering work previously carried on by The Toltz Engineering Company, the reorganized company engineers the general field of architecture, specializing upon industrial and public buildings.

E. Rees, of Chicago, Ill., has assumed the duties of chief division lubrication engineer, Sinclair Refining Company, St. Paul, Minn.

Hillard W. Jarrett has been released from the service as ensign, Naval Aviation, Supervisor of Aircraft Production, and has accepted the position of assistant fuel engineer, U. S. Bureau of Mines, Pittsburgh, Pa.

Lieut.-Col. John J. Swan, formerly Personnel Branch, Operation Division, General Staff—after the armistice, Classification Division, Adjutant General's Office, resigned April 7, to become associated with the Prest-O-Lite Company, of Indianapolis, Ind.

S. Clifford Merrill has become associated with the United States Aluminum Company, Edgewater, N. J., as mechanical engineer.

George W. Cravens has left Government service and will establish himself independently as a consulting engineer with headquarters at Westfield, N. J., and a branch office in New York City. Mr. Cravens was automotive engineer in the Maintenance Division of the Motor Transport Corps, Washington, D. C. Upon leaving the Army he was granted a commission as Major in the Reserve Corps.

George Wilfert, Captain Ordnance Department, U.S.A., has received his discharge from the service and has accepted a position with the Remington Arms Company, Ilion, N. Y., as consulting engineer on sporting rifles.

Ralph W. E. Yardley, recently Captain in the Ordnance Department, in charge of the construction of Inspection Division Proving Grounds during the war and later in charge of the Buildings and Land Section of the Ordnance Department Salvage Board, has resigned his commission and has become associated with Perkins, Fellows and Hamilton, architects.

Frank P. Rhame, Captain Ordnance Department, U.S.A., has secured his release from military service and has become associated with the Lunkenheimer Company, of Cincinnati, Ohio, in charge of a branch of the sales department which is devoted to power-plant development.

Jacob A. Teach, Chairman of the Minnesota of the Am. Soc. M. E., 1918-1919, has assumed the duties of contracting engineer, mechanical and structural departments of the Minneapolis Steel and Machinery Company, New York.

John Frick, for many years in charge of the designing, developing and constructing of the automatic vending machines used by the Horn and Hardart Baking Company, Philadelphia, Pa., has severed his connection as superintendent and designer of the machinery department to enter into business for himself as designer of tools and automatic machines, with offices in Philadelphia, Pa.

Col. H. M. Byllesby, president of H. M. Byllesby and Company, has been elected president of the Chicago branch of the National Security League.

Through an error, Arthur A. Merry's position with the Pratt and Whitney Company, Hartford, Conn., is given in the new issue of the Year Book as assistant works manager. Mr. Merry is associated with the company as production manager.

APPOINTMENTS

William D. Ennis, who has, since his release from military service, been acting professor of mechanical engineering at Columbia University, has been appointed professor in marine engineering in the Post-Graduate Department of the United States Naval Academy.

John H. Romann, in charge of the export department of Joseph T. Ryerson and Son, New York, has been appointed the company's representative for France, Belgium, Holland, Switzerland, Italy, Spain and Portugal. Mr. Romann sailed for France in March and will make his permanent home in Paris.

Fred W. Fischer, recently assistant power superintendent of the DuPont Engineering Company, Nashville, Tenn., has been appointed mechanical superintendent in charge of power, electric and maintenance divisions. This plant was recently taken over by the Ordnance Department and will be known as the Old Hickory Powder Plant.

LIBRARY NOTES AND BOOK REVIEWS

Aeroplane Construction and Assembly. By J. T. King and N. W. Leslie. Press of the William Hood Dunwoody Industrial Institute, Minneapolis. Cloth, 6 x 9 in., 115 pp., 77 illus., 5 pl., $1.50.

This work is intended as a practical manual for mechanics engaged in constructing and rigging airplanes and as a guide to instructors. Airplane assembly, construction and materials and the theory of flight are discussed.

Industrial Goodwill. By John R. Commons. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 8 in., 213 pp., 3 charts, $2.

The author discusses the present-day problems of labor and capital, their relations to each other, and the method of solving them which have been practiced or proposed. The contents: Commodity, Machinery, Goodwill, The Public, Democracy, Solidarity, Theory and Practice, Security, Labor Market, Insurance, Health, the Shop, Education, Loyalty, Personalty, Depression, The World.

Iron and Steel. (A pocket encyclopedia.) Including Allied Industries and Sciences. By Hugh P. Tiemann, with an Introduction by Henry Marion Howe. Second edition. McGraw-Hill Book Co., Inc., New York, 1919. Flexible cloth, 4 x 7 in., 514 pp., $4.

In a volume of pocket size the author provides a combination of dictionary encyclopedia and handbook of the iron and steel industries, intended for the metallurgist. The number of terms, and the text also, have been increased about one-half, the chief additions being more extended discussions of heat treatment, physical properties and testing, and of metallographic subjects.

The Mineral Deposits of South America. By Benjamin L. Miller and Joseph T. Singewald. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 598 pp., illus., maps, $5.

An account of the economic geology of the countries of South America, based on an extended visit by the authors in 1915, and a study of the literature. It forms a digest of the available information on the mineral deposits of the continent. Selected bibliographies are appended to each chapter and an adequate index is provided.

Mining Practices. Compiled from the *Engineering and Mining Journal* by the Editorial Staff. Mc-Graw Hill Book Co., Inc., New York, sole selling agents, 1919. Cloth, 9 x 12 in., 105 pp., 56 illus., 11 tables, $1.50.

These articles have been selected to illustrate the range in conditions that must be met in mining operations and to indicate in both a general and a specific way how mining practices are developed.

Office Administration. By J. William Schulze. First edition, second impression. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 5 x 8 in., 295 pp., illus., folded chart, $3.

Written to present a thorough discussion of the principles and methods which underlie efficient and economical management, for use by executives and students of business. It embodies the author's added experience and observation and is intended to replace his earlier book, The American Office.

Office Management. Its Principles and Practice covering Organization, Arrangement, and Operating with Special Consideration of the Employment, Training and Payment of Office Workers. By Lee Galloway. Second printing. The Ronald Press Co., New York, 1919. Flexible leather, 6 x 9 in., 701 pp., 97 illus., 1 pl., $6 (delivered).

This book is intended as an exposition of the basic principles of office administration in its widest sense, with adequate illustration by examples of successful practice.

Physics and Chemistry of Mine Ventilation. A Practical Handbook for Vocational Schools, and for those qualifying for mine foreman and mine inspector certificates. By Joseph J. Walsh.

Second edition. D. Van Nostrand Co., New York, 1918. Cloth, 5 x 8 in., 219 pp., illus., tables, $2.

A textbook of theory and practice for students with limited mathematical knowledge. This edition has been thoroughly revised and a chapter on the sampling and analysis of mine gases has been added.

Principles of Radiotelegraphy. Prepared in the Extension Division of the University of Wisconsin, by Cyril M. Jansky. First edition. McGraw-Hill Book Co., Inc., New York, 1919. (Engineering Education Series.) Cloth, 6 x 9 in., 242 pp., 179 illus., $2.

A textbook in which the use of mathematical expressions is employed, while an attempt has been made to explain the principles involved so fully that a reader unable to follow the mathematical demonstrations may still acquire some understanding of the subject.

A considerable part of the book is devoted to a discussion of electromagnetic theory and apparatus in order that the student may acquire an intelligent idea of the principles of the operation of radiotelegraphic apparatus.

Punches and Dies. Layout, Construction and Use. By Frank A. Stanley. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 434 pp., 618 illus., $4.

This book has been written to provide die-makers, tool-makers, and tool draftsmen with certain definite information heretofore not available as a whole. Almost ninety per cent of the material, the author states, has not been published before.

Quantitative Analysis. By Edward G. Mahin. Second edition. McGraw-Hill Book Co., Inc., 1919. Cloth, 5 x 8 in., 605 pp., 122 illus., tables, $3.50.

The author has endeavored to produce a volume that would occupy a position between the complete reference work and the bare outline of laboratory exercises. It covers the material that he wishes to take up in his college courses and at the same time presents a theoretical and practical discussion of the subject. In addition to the presentation of the general subject, a section on the analysis of industrial products and raw materials is included. This edition has been carefully revised and partly rewritten, and new material has been added.

Sewage Disposal. By Leonard P. Kinnicutt, C. E. A. Winslow, and R. Winthrop Pratt. Second edition, rewritten. John Wiley & Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 547 pp., 141 illus., 136 tables, $4.

This volume offers a general survey of the problem from the various viewpoints of the chemist, the sanitary biologist and the engineer, with particular reference to the conditions of American practice. The aim has been to discuss rather fully the fundamental principles of chemistry and bacteriology which are involved and to include the more important aspects of the engineering works designed to carry them into operation. This edition has been completely rewritten so as to bring in new data and recent viewpoints on all the topics treated. Several chapters have been much enlarged and several new ones have been added.

Structural Engineers' Handbook. Data for the Design and Construction of Steel Bridges and Buildings. By Milo S. Ketchum. Second edition. McGraw-Hill Book Co., Inc., 1918. Flexible cloth, 6 x 9 in., 896 pp., 165 tables, $5.

In preparing the new edition of this working manual for engineers, draftsmen and students, the author has added details for steel windows and doors, data on cement and gypsum tile roofs, solutions for bending moments in mill-building columns and stresses in stiff frames, has rewritten and enlarged the chapter on steel highway bridges, and has corrected all known errors.

ACCESSIONS TO THE LIBRARY

Advantages of Rope Transmission in Textile Plants. By Frederick S. Greene. Transactions No. 76 of the New England Cotton Manufacturers' Association, *Boston, Mass., 1904.* Gift of Geo. F. Fowler.

Aeronautical Engineering and Airplane Design. By Lieut. Alexander Klemin. *New York, 1918.*

The Alkali Industry. By J. R. Partington. Industrial Chemistry Series, edited by S. Rideal. *London, 1919.* Purchase.

An Interpretation of the Engine Fuel Situation. By J. E. Pogue. 1919. To be presented at annual meeting of the Society of Automotive Engineers, Feb. 4-6, 1919. Gift.

Anaconda Reduction Works, The. Anaconda Copper Mining Company, *Anaconda, Mont.,* Jan. 1919. Gift of Mr. Benj. B. Thayer of the Company.

Annuaire de la Houille Blanche Francaise. By M Auguste Pawlowski. 2nd year. *Paris, 1918-1919.* Gift.

Boston Transit Commission. 15th Annual Report for the year ending June 30, 109. Gift of Geo. F. Fowler.

Chlorine Control Apparatus. Wallace & Tiernan Co., Inc. *New York, 1919.* Gift of company.

Comptes-Rendus de l'Athénée Louisianais. Vol. 4, no. 3. Gift of Wm. Beer.

Comunicacoes da Comissao do Servico Geológico de Portugal. Tom. XII., 1917. *Lisboa.* Gift.

De Beers Consolidated Mines, Ltd. 30th Annual Report for year ending June 30, 1918. *Kimberley, So. Africa.* Gift of Company.

Dyeing with Coal Tar Dyestuffs. By C. M. Whittaker. Industrial Chemistry Series, edited by S. Rideal. *London, 1919.*

Suggested College Course on the Human Side of Engineering. By Industrial Service Movement, New York.

THE ENGINEERING INDEX

Published Monthly by The American Society of Mechanical Engineers

The Engineering Index was Founded in 1884 by the Association of Engineering Societies; Published from 1895 to 1919 by The Engineering Magazine Company; and Acquired January 1919 by The American Society of Mechanical Engineers

THE following pages form a descriptive Index to articles on engineering and related subjects in current periodicals. In its preparation the Society's engineering staff regularly examines all of the technical journals and society publications received by the Engineering Societies Library, which form one of the greatest and most complete collections of scientific periodicals in the world, comprising upward of 1100 distinct publications in some ten languages. Cross-references are freely introduced in the Index, and in all cases where the titles of articles are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC COPIES OF ARTICLES LISTED

THE Society is prepared to supply photostatic copies (white printing on brown background) of any of the articles listed. Copies of the periodicals themselves, or clippings of articles, cannot be supplied.

Price of each print (up to 11 x 14 in. in size), 25 cents plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Those holding coupon books for clippings formerly issued by The Engineering Magazine Company may use the coupons in payment for photostatic prints. In ordering, state plainly

(1) Page number of Index on which item appears
(2) Title of article
(3) Name of periodical.

Orders should be sent to

Harrison W. Craver, *Director,*
Engineering Societies Library,
29 West 39th Street, New York City.

DIVISIONS OF THE ENGINEERING INDEX

Mechanical Engineering

AIR MACHINERY

Compressed-Air Applications

Compressed Air in the Manufacture of Concrete Pipe, D. W. C. Grove. Compressed Air Mag., vol. 24, no. 4, Apr. 1919, pp. 9104-9106, 1 fig. Filling and tamping forms with pneumatic rammer.

See also MECHANICAL. ENGINEERING, Lubrication (Compressors, Air).

CORROSION

Chemistry of Corrosion, Non-Ferrous Metals

Fourth Report to the Corrosion Committee of the Institute of Metals, Guy D. Bengough. Iron & Coal Trades Rev., vol. 98, no. 2665, Mar. 28, 1919, pp. 388-389. Nature of actions that take place when zinc, copper, aluminum, 70:30 brass, etc. corrode in neutral or nearly neutral liquids; behavior of condenser tubes in similar liquids, and variations in behavior in different samples of tubes of the same composition. Also in Min. Jl., vol. 124, no. 4362, Mar. 29, 1919, pp. 190-191. Also abstracted in Engineer, vol. 127, no. 3300, Mar. 28, 1919, pp. 300-301.

Rustproofing

Rustproofing Steel. Machy. (N. Y.), vol. 25, no. 8, Apr. 1919, pp. 736-737, 2 figs. Methods used in plant of Hudson Motor Car Co., Detroit, Mich., for rustproofing passenger-car steel bodies preparatory to painting by means of deoxidine process.

Parker Rustproofing Process, Edward K. Hammond. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 851-854, 4 figs. Method which is said to be applicable to machine surfaces without changing their shape or size.

Ships

Corrosion of Ships. Am. Mar. Engr., vol. 13, no. 9, Sept. 1918, pp. 8-9. Manner of protection against corrosion. From Liverpool Jl. of Commerce.

FORGING

Dies

Obtaining Maximum Service from Dies, James C. Cran. Am. Drop Forger, vol. 5, no. 4, Apr. 1919, pp. 172-173 and p. 185. Electric steel recommended.

See also Hammer and Dies below.

Engine Cylinders

Operations on the Liberty Motor Cylinders—I, Fred H. Colvin. Am. Mach., vol. 50, no. 16, Apr. 17, 1919, pp. 757-758, 6 figs. Method of forging.

Hammer, Bement Steam

Forgings from Forty-Eight-Inch Ingots. Pac. Mar. Rev., vol. 16, no. 4, Apr. 1919, pp. 118-119, 2 figs. Double-arch Bement steam hammer said to be capable of delivering a blow of 150,000 lb.

Hammer and Dies

A Review of Hammer and Die Problems, R. C. Jennings. Am. Drop Forger, vol. 5, no. 4, Apr. 1919, pp. 180-182, 3 figs. Describes machine patented by writer and designed to use either American or English die blocks.

FOUNDRIES

Brass Foundry

Materials and Chemicals Used in Brass Foundry Practice—V, Charles Vickers. Brass World, vol. 15, no. 4, Apr. 1919, pp. 113-115, 2 figs. History, properties, appearance, physiological action and commercial use of substances commonly used in brass founding. Method for making phosphor-tin.

Crucibles

The Use and Abuse of Crucibles, A. C. Bowes. Min. & Sci. Press, vol. 118, no. 15, Apr. 12, 1919, pp. 505-506, 3 figs. Alleges that principal cause of failure of crucibles is lack of proper annealing; states that a temperature of 250 deg. fahr. is required to dispel moisture absorbed from atmosphere.

Engine Castings

Inland Plant Sets Record on Marine Engine Castings, D. M. Avey. Foundry, vol. 47, no. 5, Apr. 15, 1919, pp. 196-204, 23 figs. Rapid production of castings at plant of Hooven, Owen, Rentschler Co., builders of Corliss type engines; foundry said to have turned out heavy castings for a complete engine per day.

Malleable Castings

Malleable Plant to Revert to Destined Work. Foundry, vol. 47, no. 5, Apr. 15, 1919, pp. 221-224, 6 figs. General arrangement of Nat. Malleable Castings Co. foundry where cast-steel anchor chains are being manufactured. Plant was originally designed for production of malleable castings for automobile service and is being refitted to undertake this work.

Patterns

Patternmaking Methods—II, Joseph A. Shelly. Machy. (N. Y.), vol. 25, no. 8, Apr. 1919, pp. 722-726, 7 figs. Examples of pattern work and methods used in general pattern making practice.

Patterns and Moulds for Engine Cylinder Castings—I, Joseph Horner. Foundry Trade Jl., vol. 21, no. 206, Feb. 1919, pp. 90-94, 13 figs. Principles which control the various classes of work, by reason of the double practice of both patternshop and foundry.

Risers

Hot Water Practice in Relation to Risers—I, W. B. Gray. Metal Worker, vol. 91, no. 15, Apr. 11, 1919, pp. 455-456. Method of determining size.

Sand Blast

Application of the Sand-Blast to General Foundry Work, Parts I and 2, H. D. Gates. Pt. 1: Metal Trades, vol. 10, no. 4, Apr. 1919, pp. 172-175, 4 figs. Discusses general question of cleaning castings by sand blast and describes various types of hose machines. Pt. 2: Can. Foundryman, vol. 10, no. 4, Apr. 1919, pp. 90-94, 9 figs. Its applicability and advantages for general foundry work together with examples and data of what has actually been accomplished.

Standardization

Standardisation of Foundry Practice, S. W. Wise. Foundry Trade Jl., vol. 21, no. 206, Feb. 1919, pp 95-97. Records of operation of various cupolas and discussion of the possibility of standardizing cupola practice. Paper read before Newcastle Branch, British Foundrymen's Asso.

Steel Castings

Steel Castings from the Engineer's Viewpoint, H. A. Neel, Proc. Steel Treating Research Soc., vol. 2, no. 3, 1919, pp. 14-16 and 43-44 and (discussion) pp. 44-50. Developments in molding and metallurgical practice which have made it possible to use steel castings in operations formerly undertaken with forgings.

Manufacture of Steel Castings by Various Processes, David D. MacGuffie. Foundry Trade Jl., vol. 21, no. 206, Feb. 1919, pp. 85-89, 3 figs. Remarks on the crucible, Tropenas, Stock oil-fired converter, and electric-furnace processes. Paper read before British Foundrymen's Assn.

See also MARINE ENGINEERING, Yards (Castings); ELECTRICAL ENGINEERING, Furnaces (Crucibles).

FUELS AND FIRING

Ash

Fusibility of Ash from Coals Found in the Interior Province, W. A. Selvig, W. C. Ratliff and A. C. Fieldner. Coal Age, vol. 15, no. 16, Apr. 17, 1919, pp. 698-703. Table of softening temperatures of coal ash from coals of interior province obtained at Fuels Chemical Laboratory tests conducted by Bureau of Mines.

Coal, Lignite

Lignite Coals and Their Utilization, C. C. O'Harra. Pahasapa Quarterly, vol. 8, no. 2, Feb. 1919, pp. 15-35, 18 figs. Extent and estimated reserve of coal deposits of the world; developments in industrial recoveries of coal by-products.

Combustion Experiments with North Dakota Lignite, Henry Kreisinger, C. E. Augustine and W. C. Harpster. Dept. of Interior, Bur. of Mines, tech. paper 207, 44 pp., 13 figs. Tests were made by burning lignite—both as it comes from mine and as carbonized residue from gas retorts—at various rates in experimental furnaces and by studying process of combustion.

Coal, Pulverized

Pulverized Coal and Its Bearing on the Fuel Situation, H. G. Barnhurst. Manufacturers Rec., vol. 75, no. 16, Apr. 17, 1919, pp. 107-108. Table giving cost of preparing coal in plants of various capacities.

The Use of Pulverized California Coal, Chas. H. Delany. Jl. Electricity, vol. 42, no. 8, Apr. 15, 1919, pp. 357-359. Its substitution for fuel oil is discussed from standpoint of initial costs and comparative operating expense. Paper prepared for Spring Convention of Pac. Coast Section N. E. L. A. by Engineering Committee.

Pulverized Coal as the Reconstruction Fuel for all Industrial Heating Operations, C. F. Herrington. Iron & Steel of Can., vol. 2, no. 4, Apr. 1919, pp. 77-83, 4 figs. Equivalent prices of powdered coal and other fuel. Details of powdered-coal plant.

Coal, Southwestern

Burning Coals of the Southwest, W. M. Park. Power, vol. 49, no. 15, Apr. 15, 1919, pp. 574-575, 4 figs. Large furnace volumes, liberal grate area and unusual quantities of refractory material in the ignition arch and bridge wall, are advocated.

Coal, Storage of

Storage of Coal and Spontaneous Combustion. Ry. & Locomotive Eng., vol. 32, no. 4, Apr. 1919, pp. 99-100. Analysis of causes and approved methods of suppression.

Coal, Western

Western Coal, R. D. MacLaurin. Can. Chem. Jl., vol. 3, no. 4, Apr. 1919, pp. 124-125. Means taken by Government officials to stimulate development of these resources. (Concluding article.)

Draft

The Securing of Economy in the Burning of Fuel, J. F. Patton. Power House, vol. 13, no. 4, Apr. 5, 1919, pp. 94-95, 3 figs. Influence of draft on burning of coal; use of draft gages; importance of eliminating air leaks.

Firing

Utilization of Fuels in Industrial Furnaces (L'utilisation des combustibles dans les foyers industriels), Roger Hartmann. Société Industrielle de l'Est, Bul. 145, Feb. 1919, pp. 3-21, 3 figs. Theoretical study of economical combustion based on chemical phenomena of ignition; means suggested by the governments of England, America and France for efficient utilization of fuels.

Flue-Gas Analysis

Combustion and Flue Gas Analysis. Dept. of the Interior, Bur. of Mines, tech. paper 219, 12 pp., 6 figs. Recommends use of measuring instruments. Reprint of Eng. Bul. no. 4, prepared by United States Fuel Administration.

Fuel Conservation

National Saving of Fuel and Power, Arthur V. White. Can. Engr., vol. 36, no. 11, Mar. 13, 1919, pp. 299-303. Activities of Canadian Committee of Conservation.

Gas, Blast-Furnace

Fuel Economy (Economies de combustible dans une aciérie moderne). Métallurgie, vol. 51, no. 14, Apr. 2, 1919, pp. 777-778. Utilization of gases from blast furnaces. (Concluded.)

Gas and Oil Fuels

See Producer Gas, page 14-*a*; Items under INDUSTRIAL TECHNOLOGY; and Oil and Gas, under MINING ENGINEERING.

Grates

Recent Improvements in Sintering Equipment and Practice. Eng. & Min. Jl., vol. 107, no. 17, Apr. 26, 1919, pp. 744-745, 3 figs. Device intended to prevent grates from getting dirty. Designed for use with the straight-slot type of grate.

Oil Firing

Saving the Waste in the Chimney—V, Robert Sibley and Chas. H. Delany. Jl Electricity, vol. 42, no. 7, Apr. 1, 1919, pp. 318-320, 7 figs. Operating test of steam power plant operated by fuel oil in San Francisco.

Peat

The Utilisation of Peat for Power Generation—I & II, John B. C. Kershaw. Engineer, vol. 127, nos. 3298 & 3299, Mar. 14 and 21, 1919, pp. 239-240 and 265-267, 11 figs. Processes for carbonizing followed at various plants in France, Sweden and Germany.

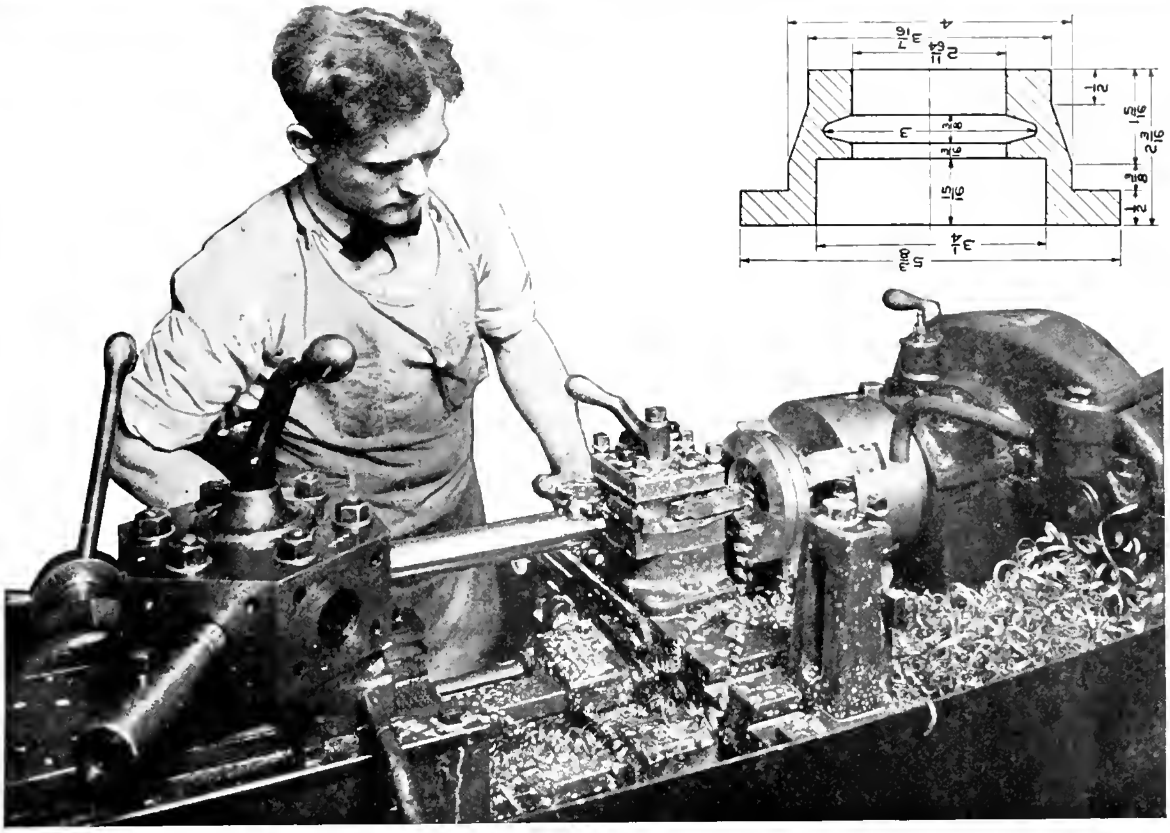
FURNACES

Davis Furnace for Baking Electrodes

Davis Furnace for Baking Electrodes (Four Davis à cuire les électrodes). Revue Généra de l'Electricité, vol. 5, no. 12, Mar. 22, 191 p. 458. Installed at Hecla works of Diamor Foundry, Luton, England, where, it is sai



Value of the Square Turret

THIS shows the amount of material removed and how well the many operations on these tough power sprocket clutches were finished on the No. 4 Universal Screw Machine. The hexagon turret was used only for boring. The square turret, loaded to capacity with cutters, did the rest with the aid of its eight power cross and longitudinal feeds.

For Work Too Complicated for Ordinary Screw Machines

The special features of the No. 4 Universal (in this case the unusual use for the square turret) adapt them to a wide range of work too complicated for ordinary screw machines or turret lathes

SEND FOR DETAILS
Turret Lathes and Screw Machines

Benson Brothers, Sydney and Melbourne. A. Asher Smith, Sydney. A. R. Williams Machinery Co., Ltd., Toronto, St. John, Winnipeg and Vancouver. Williams & Wilson, Ltd., Montreal.

30,000 tons of electric steel are produced per year at average consumption of 11 lbs. of electrode per ton of steel.

Gas Furnaces

Heating Gas Furnaces, O. L. Kowalke. Gas Rec., vol. 15, no. 7, Apr. 9, 1919, pp. 231-234, 6 figs. Tests to determine maximum temperature which can be obtained in a given furnace, using three types of mixers with regulated and unregulated air supply, by burning carbureted water gas in bunsen flame and also under adapted surface combustion conditions. Paper before Wis. Gas Assn.

Gas Furnaces as Re-Heaters of Iron Piles, etc. Iron & Coal Trades Rev., vol. 98, no. 2664, Mar. 21, 1919, p. 354. Function gas furnace has to perform in smelting steel and in reheating iron.

Heat-Treating Furnaces

Heating Furnaces and Annealing Furnaces—III, W. Trinks. Am. Drop Forger, vol. 5, no. 4, Apr. 1919, pp. 174-180, 8 figs. Method of computing fuel consumption from losses.

The Design of Heating Furnaces from a Practical Standpoint, George J. Hagan. Proc. Engs. Soc. Western Pa., vol. 35, no. 1, Feb. 1919, pp. 31-47 and (discussion) pp. 48-57, 5 figs. On design and method of construction, with reference to furnaces used in sheet and tin-plate industry and to a continuous rotary furnace for wash and heat.

Melting Furnaces

Metallurgical Furnaces, Adolph Bregman. Metal Indus., vol. 17, no. 4, Apr. 1919, pp. 159-162, 7 figs. Conditions that govern size, shape and type of metal-melting furnaces.

GAGES

Hoke Precision Gages

Manufacture of Hoke Precision Gages at the Bureau of Standards, H. L. van Keuren. Am. Machinist, vol. 50, no. 14, Apr. 3, 1919, pp. 625-630, 6 figs. Gage blocks are being produced at the Bureau with an accuracy limit of a few millionths of an inch. Apparatus used in testing flatness and parallelism to one millionth of an inch. Development of process for their commercial manufacture has taken place within period of 6 months. Special reference is made to light-weight interference method for determining accuracy.

Johanssen Tolerances

Johanssen System of Tolerances. Machinery, vol. 13, no. 339, Mar. 27, 1919, pp. 718-719, 1 fig. On Swedish system based on diameter of hole.

Measurement of Gages

The Measurement of Gauges—I & II, E. A. Forward. Engineer, vol. 127, nos. 3300 & 3299, Mar. 21 and 28, 1919, pp. 282-283 and 294-295, 24 figs. Methods used for measuring three classes of gages: (1) plate or form gages the profiles of which are combinations of straight lines and curves; (2) conical plugs, rings and disks, combinations of cones with cylinders and planes, and castellation gages; (3) position gages.

Plug Gages, Angular

Angular Plug-Gage Making, Hugo Pusep. Am. Machinist, vol. 50, no. 14, Apr. 3, 1919, pp. 635-640, 15 figs. Lays emphasis on elimination of errors in preliminary operation, in order to prevent their accumulation and the appearance of serious defects which will be difficult to eliminate in later operations.

GAS ENGINEERING

Distributing Systems

Increasing Capacity of Low-Pressure Mains by Admitting Gas at More Than One Point, A. C. Howard. Am. Gas Eng. Jl., vol. 110, no. 16, Apr. 19, 1919, pp. 329-331. Using an artificial gas distributing system for natural gas. From Gas & Elec. News.

Flow of Gas

Flow of Gases Under Heavy Pressure (Sur l'écoulement des gaz à tres fortes pressions), A. Rateau. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 7, Feb. 17, 1919, pp. 330-335. Changes in gas equation to make it applicable to the flow of gases in guns.

Lighting

The Group and Duct System of Lighting. Gas World, vol. 70, no. 1810, Mar. 29, 1919, pp. 237-239, 3 figs. Also in Gas Jl., vol. 146, no. 2916, Apr. 1, 1919, pp. 30-32, 3 figs. System is designed to utilize one injector for supplying any number of burners, in place of each individual burner having gas injector and air intake. There are three separate sets of types—one supplying high-pressure gas, one carrying air to an injector for mixing with the gas, and one supplying mixture of gas and air from injector to burners.

Mantles, Gas

Influence of Quality of Gas on the Efficiency of the Gas Mantle, Pts. 2 and 3, R. S. McBride, W. A. Dunkley, E. C. Crittenden and A. H. Taylor. Gas World, vol. 70, nos. 1805 and 1810, Feb. 22 and Mar. 29, 1919, pp. 128-130 and 233-236, 10 figs. Pt. 2: Graphs showing effect of gas-pressure variations upon efficiency, gas consumption and candlepower of various lamps. Pt. 3: Lean water gas reported to have shown qualities for mantle lighting superior to those of rich water gas in proportion to total heating values. Section 1 appears in Gas World for Feb. 8.

Production, Gas

Distribution of Light, Heat, and Motive Power by Gas, Dugald Clerk. Gas Journal, vol. 145, no. 2915, Mar. 25, 1919, pp. 637-640 and (discussion) pp. 640-642; also Gas World, vol. 70, no. 1809, Mar. 22, 1919, pp. 210-212. Efficiency of gas production compared with efficiency of electricity generation. Claim to electric superiority over gas in coal economy considered as unjustified. Thermal efficiency of carbonizing gas coal in horizontal retorts. Paper read before Roy. Soc. of Arts.

Purification, Oil Gas

Liquid Purification of Gas, O. B. Evans. Gas Rec., vol. 15, no. 7, Apr. 9, 1919, pp. 215-216. Concluded from tests of Atlantic Refining Co. that cold liquid purification of oil gas may result in a loss of 25 per cent in candle power. Paper before Am. Gas Assn.

Principles of Gas Purification and Purifier Design, F. W. Steere. Gas Age, vol. 43, no. 7, Apr. 1, 1919, pp. 361-363, 2 figs. Review of methods and suggestions regarding improvements in apparatus employed in removing sulphur from gas. (Concluded.)

Water Gas

Gas Machine Factors Involved in the Manufacture of Carbureted Water Gas. Am. Gas Eng. Jl., vol. 110, no. 15, Apr. 12, 1919, pp. 312-316 and 320-324. Fundamentals upon which process is dependent and suggestions toward locating cause of variations in results.

HANDLING OF MATERIALS

Car Dumper

The Biggest Car Dumper in the World. Sci. Am., vol. 120, no. 15, Apr. 12, 1919, pp. 363 and 382, 4 figs. Virginian Ry. installation designed to handle two 60-ton cars simultaneously; cars are tipped sidewise.

Ship Loading

Radical Departure in Loading Ocean Freighters. Ry. Age, vol. 66, no. 16, Apr. 18, 1919, pp. 981-984, 7 figs. Reported that Erie R. R. utilizes existing equipment in handling 50 locomotives direct from pier to ship.

HEAT-TREATING

Brass

Effects of Heat when Annealing Alloys, H. C. H. Carpenter and L. Traverner. Am. Drop Forger, vol. 5, no. 4, Apr. 1919, pp. 193-196, 2 figs. Chart showing ultimate stress after heating various metals, also time required to cause drop of three points in scleroscope hardness in a brass strip. Paper presented before Inst. Metals London.

Bronze

Results of Heat-Treating Bronze Castings, George F. Comstock. Foundry, vol. 47, no. 5, Apr. 15, 1919, pp. 189-194, 18 figs. Effects of annealing bronze-alloy castings studied with the aid of photomicrographs of test sections.

Case-Hardening

The Application of Heat in Case-Hardening, Theodore G. Selleck. Jl. Am. Steel Treaters Soc., vol. 1, no. 3, Dec. 1918, pp. 87-98, 11 figs. Value of laboratory reports of analysis and specifications under which material was shipped from manufacturer, as a source of information for determining nature and quality of material to be treated.

Case-Hardening of Carbon Steels (Mécanisme de la trempe des aciers au carbone), Pierre Chevenard. Revue de Métallurgie, vol. 16, no. 1, Jan.-Feb. 1919, pp. 17-79, 36 figs. Results of micrographic analysis and tests have caused writer to establish that case-hardening results from transformation at low temperatures (150 to 300 deg. cent.) γ-α of austenite; when hardening is complete, steel is made up almost exclusively of martensite. Thus the theory announced by Le Chatelier in 1895 appears to have been confirmed.

Notes on the Process of Case-Hardening, J. R. Handforth. Can. Machy., vol. 21, no. 12, Mar. 20, 1919, pp. 277-280, 10 figs. Photomicrographs of structures produced by case-hardening. From Machine Tool Rev.

Improved Packing Methods for Carburizing, William H. Addis. Am. Mach., vol. 50, no. 15, Apr. 10, 1919, pp. 679-680, 3 figs. Two methods for spacing pieces.

Steel, Low-Carbon

Heat-Treatment of Low-Carbon Steel, W. M. Wilkie. Can. Machy., vol. 21, no. 17, Apr. 24, 1919, pp. 396-401, 12 figs. Characteristic structures found in steel, their formation by heat treatment and effect each has in quality of steel. Paper read before Toronto Section Am. Soc. Mech. Engrs.

Steel, Tool

Heat Treatment of Tool Steel, S. N. Brayshaw. Ironmonger, vol. 167, no. 2369, Apr. 12, 1919. Believes that precision can only be attained by makers and users of steel by carrying out heat treatments in liquids instead of in atmospheric furnaces. Paper read before Birmingham Metallurgical Soc.

See also MECHANICAL ENGINEERING, *Furnaces (Heat-Treating Furnaces).*

HEATING AND VENTILATION

Hot-Water Heating

Designing Data as Applied to a Large Hot-Water Heating Plant, George E. Reed. Heat & Vent. Mag., vol. 16, no. 4, Apr. 1919, pp. 26-34, 13 figs. Western practice, illustrated in layout for Franklin High School, Portland, Ore. (Concluded.)

Industrial Heating

Saving Steam in Industrial Heating Systems. Dept. of the Interior, Bur. of Mines, tech. paper 221, 14 pp., 7 figs. Calls attention to faults of design and operation which lead to uneconomical use of live steam for heating and other purposes. Reprint of Eng. Bul. no. 6, prepared by U. S. Fuel Administration.

Steam Flow

Simplifying Calculations for Flow of Steam in Pipes. Heat. & Vent. Mag., vol. 16, no. 4, Apr. 1919, pp. 19-26, 3 figs. Curves based on generally acepted formulæ.

Tunnel, Simplon

The Ventilation Plant of the Simplon Tunnel (Die Ventilationsanlage des Simplon-Tunnels), F. Rothpletz. Schweizerische Bauzeitung, vol. 73, nos. 1, 2, 5 and 7, Jan. 4, 11 and Feb. 1, 15, 1919, pp. 3-4, 14-16, 41-44 and 72, 20 figs. Instead of two fans, one at each entrance, 1913 project provided for one ventilation plant at Brig with two 11½-ft. fans with central suction openings 8.5 ft. in diameter. Arrangement of plant and details of operation of fans as worked out from study of barometric conditions and past experience are mentioned.

HOISTING AND CONVEYING

Conveyor, Cinder

New Type of Cinder Conveyor. Ry. Age, vol. 66, no. 16, Apr. 18, 1919, p. 1017, 1 fig. Conveyor discharges cinders through pipe line by action of steam jet.

Conveyors, Power Requirements of

Power Plant Management; Coal and Ash Handling—II, Robert June. Power House, vol. 13, no. 4, Apr. 5, 1919, pp. 87-89, 4 figs. Power required for various types of conveyors and conditions under which these are operated.

Conveyor, Scoop

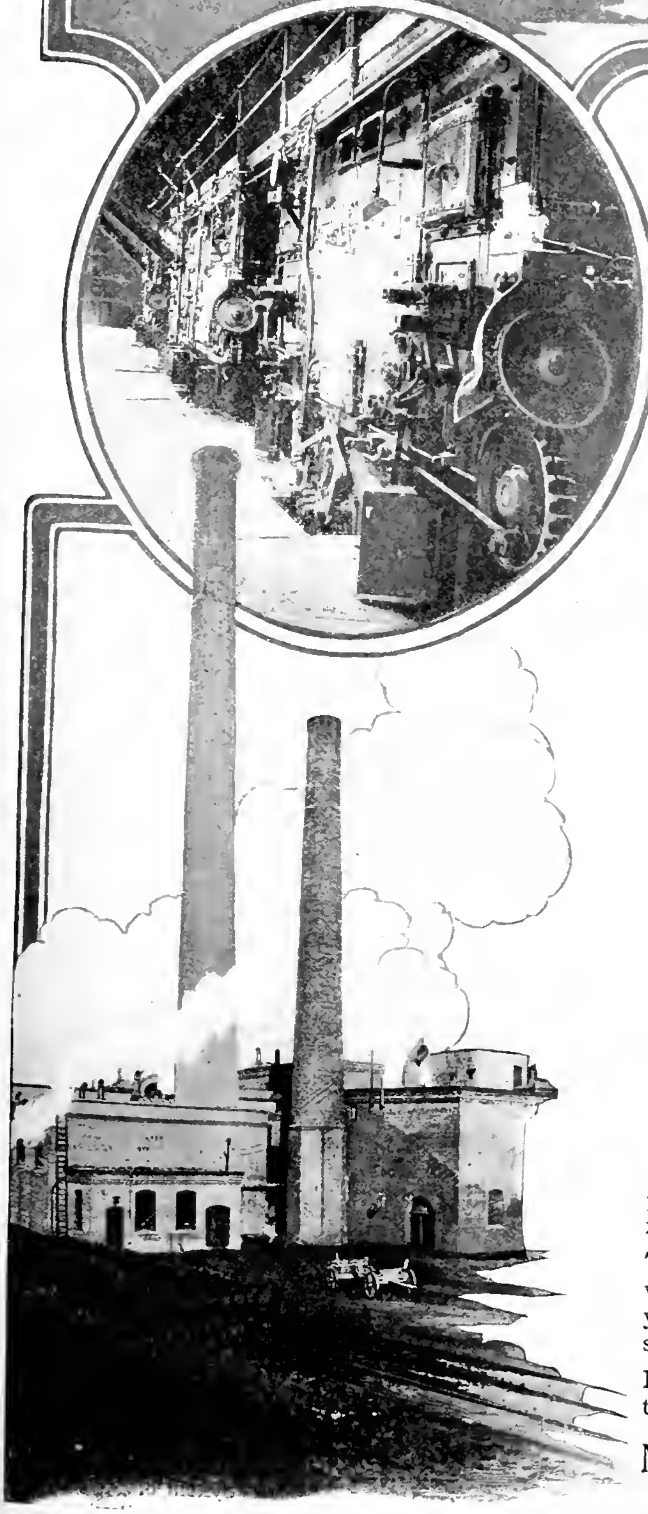
A New Type of Conveyor that Reduces the Cost of Handling Coal, Coke, Ashes, Sand, Etc. Popular Engr., vol. 11, no. 4, Apr. 1919, pp. 22-23, 6 figs., also Cement & Eng. News, vol. 31, no. 4, Apr. 1919, pp. 42-44, 7 figs. Distinctive feature is scoop on feeding end, which can be pushed or completely buried into material to be conveyed. Conveyor is equipped with a 16-inch belt and driven by 2-hp. electric motor.

A New Portable Elevator. Coal Trade Jl. vol. 50, no. 16, Apr. 16, 1919, pp. 410-411, 5 figs. Elevator has scoop on feeding end which can be pushed or completely buried into the material to be conveyed.

Cranes

Lifting Cranes in Shipbuilding Yards (Les appareils de levage dans les chantiers de constructions navales). Génie Civil, vol. 74, no. 14, Apr. 5, 1919, pp. 265-268, 8 figs. The construction and location as affecting economical and rapid transportation of material. Examples of installations in English yards.

Down in Maine



Paper Mill Plants are often tucked away in the neck of the woods. The very nature of the business places this industry nearest its source of supply.

Because of their isolation, paper mills must have equipment of unfailing reliability—good equipment upon which they can depend—such equipment as:

MURPHY AUTOMATIC FURNACES

At the Orono Pulp and Paper Company four boilers are fired by Murphy Furnaces. For every pound of paper produced these automatic stokers use the minimum of fuel—it makes little difference what the fuel is—because Murphy Furnaces "burn anything that has heat in it."

As for labor saving, Murphy Furnaces keep on operating continuously without a man in sight.

Contrast the cleanliness—the efficiency—the economy—of this or any Murphy plant with plants using the old methods of stoking.

Remember this! Just as Murphy Furnaces have forged ahead in the Paper Mill industry from 1 to 113 installations, so have they in the Chemical, Metallurgical, Textile, Steel, Automobile, Industrial, Central, Electric R. R. and Hospital.

In fact, wherever coal is used to furnish light, heat or power—wherever the service is the hardest—there you will find Murphy Automatic Furnaces.

The country is so completely dotted with installations that we can direct you to plants in your vicinity who will tell you their experiences and what Murphy Furnaces have saved for them in money, men and fuel.

If your boilers are 50 H. P. or larger you should write us today. Catalog A-6 sent on request.

MURPHY IRON WORKS, Detroit, Mich.

BURNS ANY FUEL THAT HAS HEAT IN IT

Luffing Cranes. Eng. World, vol. 14, no. 7, Apr. 1, 1919, pp. 55-57, 4 figs. Description of Toplis crane used in an English shipyard.

See also MINING ENGINEERING, Mines and Mining (Hoisting Machinery); MARINE ENGINEERING.

HYDRAULIC MACHINERY

Backwater

New Methods for the Solution of Backwater Problems, H. R. Leach. Eng. News Rec., vol. 82, no. 16, Apr. 17, 1919, pp. 768-770, 6 figs. Suggestions in regard to simplifying reduction of complications by using diagram with only one major variable.

Bernoulli's Formula

On Bernoulli's Formula (Sur la formule de Bernoulli), Emile Cotton. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 11, Mar. 17, 1919, pp. 547-549. Modification by taking into account actual conditions of motions of natural liquid in tube of finite section.

Conduit Protection

Devices for Regulating Automatically the Delivery of a Pressure Conduit (Appareils automatiques d'arrêt du débit des conduites forcées), N. de Schoulepnikow. Bulletin Technique de la Suisse Romande, vol. 45, no. 7, Apr. 5, 1919, pp. 57-59, 3 figs. Bouchayer-Viallet syphon.

Drops

Flow of Liquid Drops Through Cylindrical Pipes (Sur les lois de l'écoulement des liquides par gouttes dans des tubes cylindriques), L. Abonnenc. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 11, Mar. 17, 1919, pp. 556-557. Experimental confirmation of formula developed by Vaillant, in which time between consecutive drops is a parabolic function of weight of drop.

Flood Protection

Panels of Movable Weir Collapse Automatically. Eng. News-Rec., vol. 82, no. 17, Apr. 24, 1919, pp. 818-820, 5 figs. Details of automatic tripping control operated by float in chamber which is filled as flood rises.

Flow

On the Flow of Fluids (Sur l'écoulement des fluides), L. Lecornu. Comptes rendus des séances de l'académie des Sciences, vol. 168, no. 10, Mar. 10, 1919, pp. 481-484. Velocity of fluid in a conduit of variable cross-section.

Ram, Hydraulic

The Hydraulic Ram. Fire & Water Eng., vol. 65, no. 16, Apr. 16, 1919, pp. 873-875, 2 figs. Principle of operation and discussion of its possibilities for small-town installations.

The Hydraulic Ram, W. S. H. Cleghorne. South African Jl. Industries, vol. 2, no. 2, Feb. 1919, pp 135-142, 6 figs. Principles of action and conditions necessary for successful operation.

Turbines

Economical Operation of Water Turbines, F. H. Rogers. Elec. World, vol. 73, no. 14, Apr. 5, 1919, pp. 680-683, 7 figs. Value of principal losses that may occur and methods of locating their origin; inquiry into effect of losses on output.

Water Economy

Water Economy in Hydroelectric Plants, L. W. Wess. Elec. World, vol. 73, no. 15, Apr. 12, 1919, pp. 727-728, 1 fig. Claims that output of plant is increased by allowing excess water to run off at night.

Water Hammer

Water Hammer in Conduits of Variable Diameter (Sur les coups de bélier dans les conduites de diamètre variable), G. Guillaumin. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 12, Mar. 24, 1919, pp. 605-608. Theory based on assumption that water travels at uniform speed.

INTERNAL-COMBUSTION ENGINES

Acetylene

Acetylene Motors, C. F. Keel. Acetylene & Welding Jl., vol. 16, no. 186, Mar. 1919, pp. 48-49. General summary of actual position in regard to developments accomplished during war in utilization of acetylene as a motor fuel. (To be continued.) Translated from paper published by Swiss Acetylene Assn.

Bore-Stroke Ratio

The Problem of Bore-Stroke Ratio, Georges Funck. Autocar, vol. 42, no. 1225, Apr. 12, 1919, pp. 528-532, 4 figs. Study of bore-stroke ratio as dependent on number of cylinders, their disposition and system of cooling, and for the purpose for which engine is intended to be used.

Compound Gas Engines

Expansion, Robert Miller. Motor Boat, vol. 16, no. 8, Apr. 25, 1919, pp. 21-24, 5 figs. Possible increase in efficiency of internal-combustion engine by increasing expansion, with reference to compound gas engine with two jacketed high-pressure cylinders each discharging into a low-pressure unjacketed cylinder.

Design

A Comparison of Airplane and Automobile Engines, Howard C. Marmon. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 237-239. Deals particularly with weight in cylinder construction, design of crankshaft and crankcases and economy in fuel and oil consumption.

Diesel-Engine Pistons, Seizure of

Seizures of Diesel Engine Pistons, Edward Ingham. Electrical Review, vol. 84, no. 2160, Apr. 18, 1919, pp. 451-452. Seizures are attributed to overheating of piston and resulting expansion of metal, consequently proper lubrication and cooling of piston are advised.

Fuels

More Efficient Utilization of Fuel, Charles F. Kettering. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 263-269, 10 figs. Distillation curves of various internal-combustion engine fuels; specific gravity fuels. Conclusions obtained from examination of causes which produce cylinder knocks.

An Interpretation of the Engine-Fuel Situation, Joseph E. Pogue. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 247-252 and (discussion) pp. 252-255, 3 figs. Future of automotive industry is represented as depending on three factors: adaptability of "internal-combustion" engines to use of liquid fuel, supply of crude petroleum, and production of substitute fuel.

Fuel Economy of Automotive Engines, H. C. Dickinson. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 227-233, 6 figs. Properties of fuels which are subject to specification test are examined and trend of future development in utilization of new fuels of internal-combustion engines is discussed from viewpoint of expediency in adopting single fuel for all automotive engines.

Gas Engines, High-Power

High-Power Gas Engines, William Stead. Gas and Oil Power, vol. 14, no. 163, Apr. 3, 1919, pp. 93-96. Part large gas engine may play in state control scheme of electric power generation for power and light supply.

Motorcycle

The Engine of the Side Car Motorcycle—II, E. Cauldwell. Automotive Industries, vol. 40, no. 17, Apr. 24, 1919, pp. 911-913, 6 figs. Lift, velocity and acceleration curves for 3000 r. p. m. of crankshaft; lubrication features of 4-cyl. Henderson engine. Paper presented to Instn. Automobile Engrs.

Oil Engines

The Oil Engine—Its Economic Position in the Marine Field, Theodore Lucas. Pac. Mar. Rev., vol. 16, no. 4, Apr. 1919, pp. 93-98, 3 figs. Advantage of liquid-fuel engines over steam engines is said to consist in reduction of cost and adding to useful carrying capacity of ship. Comparison of methods of mechanical atomization with reference to arrangement of Lucas engine.

The High-Compression Oil Engine, W. G. Gernandt. Gas Engine, vol. 21, no. 5, May 1919, pp. 155-161, 3 figs. Comparison of various methods of injecting liquid fuel into combustion chamber of engine. Opinion is expressed that high-compression type of engine is suitable for burning of heavy fuel oils.

Pressed-Steel Engines

Pressed Steel Engines. Autocar, vol. 42, no. 1225, Apr. 12, 1919, pp. 537-538, 5 figs. Process for stamping from steel sheets main parts and various details of engines.

Ricardo Tank Engines

The 150 H. P. Ricardo Tank Engine, H. A. Hetherington. Automobile Engr., vol. 9, no. 125, Apr. 1919, pp. 116-120, 5 figs. Details of piston, valve and valve gear. (To be continued).

Wisconsin Engines

Liberty Line of Wisconsin Engines. Automotive Industries, vol. 40, no. 15, Apr. 10, 1919, pp. 796-798, 4 figs. Principal characteristics include unit power-plant design, aluminum crankcases, pressure lubrication and "all steel" three-point support.

See also ELECTRICAL ENGINEERING, Ignition Apparatus; MECHANICAL ENGINEERING, Motor-Car Engineering.

LUBRICATION

Compressors, Air

Lubrication of Air Compressors, H. V. Conrad. Coal Age, vol. 15, no. 16, Apr. 17, 1919, pp. 704-706, 1 fig. Discusses rate of feed and carbon-cutting methods and concludes with remarks on steam-engine lubrication.

Journal Boxes

Lubrication and Care of Journal Boxes, M. J. O'Connor. Ry. Rev., vol. 64, no. 17, Apr. 26, 1919, pp. 620-621. Directions for preparing oil and waste for packing journal boxes; reclaiming old packing removed from cars; inspection of cars so that lubricating trouble may be kept down to a minimum.

Lubricants

Lubricants for the Power Plant, Reginald Trautschold. Power Plant Eng., vol. 23, no. 8, Apr. 15, 1919, pp. 353-358, 3 figs. Qualities of a good oil; tests of grade of oil and grades for various uses.

Properties of Representative American Lubricating Oils for Use in Internal Combustion Engines. Aerial Age, vol. 9, no. 6, Apr. 21, 1919, p. 289. Table showing physical properties and percentage of distillation under 300 deg. cent. in vacuum.

See also ELECTRICAL ENGINEERING, Generators and Motors (Lubrication); MECHANICAL ENGINEERING, Motor-Car Engineering (Lubrication).

MACHINE ELEMENTS AND DESIGN

Belting

Fiber Belting (Zellstoff-Treibriemen), E. O. Rasser. Kunststoffe, vol. 8, no. 11, June 1, 1918, pp. 122-125. Describes various types such as woven paper belting, paper belting with cloth filler, paper-yarn belting, knitted paper-yarn belting, plaited belting, paper-yarn belting with wire filler, and the processes of their manufacture. Also type of joints and care of this type of belting.

Gears

Gears for Tractor Construction, E. J. Forst. Automotive Industries, vol. 40, no. 17, Apr. 24, 1919, pp. 891-892. Importance of using high-grade steel on account of resulting compactness of transmission and greater facility of enclosing it.

Worm Gear Efficiency, C. H. Calkins. Automotive Industries, vol. 40, no. 15, Apr. 10, 1919, pp 786-787, 2 figs. Bausch company's worm-wheel testing stand for determining efficiency of worm-and-wheel rear-axle drives.

Worms and Worm Gears, G. W. Carlson. Am. Mach. vol. 50, no. 17, Apr. 24, 1919, pp. 809-811. Application of this form of gearing is suggested for other purposes than automotive drives.

Gears, Magnetic

Magnetic Gears (Engrenages magnétiques), Leópold Reverchon. Industrie Electrique, vol. 28, no. 643, Apr. 10, 1919, pp. 133-135, 4 figs. Escapement wheel rotated by alternative actions of a fixed magnet on one side and a magnet attached to an oscillating pendulum on the other upon magnetic needles placed in periphery of wheel symmetrically with respect to its center.

Joints

The Design of Riveted Butt Joints, Alphonse A. Adler. Mech. Eng., vol. 41, no. 5, May 1919, pp. 433-436. Design equations derived from Schwedler's graphical method.

See also AERONAUTICS, Engines (Crankshafts).

MACHINE SHOP

Babbitting

Babbitting High-Speed Vertical Spindles, Stanley White. Wood-Worker, vol. 38, no. 2, Apr. 1919, pp. 42-43. Cautions against pouring metal before aligning spindle.

Boring, Dudgeon System of

Dudgeon System of Precision Boring. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 803-805, 7 figs. Method of boring jigs and similar work by means of simple equipment and without depending upon accuracy of machine used for operating boring bar.

Crankshaft Machining

Crankshaft Machining. Automobile Engr., vol. 9, no. 122, Jan. 1919, pp. 10-12, 11 figs.

Equipment manufactured by Le Blond Co., Cincinnati.

Cylinder Machining

Cylinder Boring and Reaming—I & II. Machinery, vol. 13, nos. 338 & 339, Mar. 20 and 27, 1919, pp. 681-689 and 713-717, 26 figs. Classification of methods, their application to different kinds of work, and illustrations of actual operations. Description of tools, fixtures and machines used.

Cylinder Grinding—II, Franklin D. Jones. Machy. (N. Y.), vol. 25, no. 8, Apr. 1919, pp. 711-715, 11 figs. On advantages of finishing cylinder bores by grinding; machines used; practice in plants making automobile and airplane engines.

Equipment Layout

Arrangement of Equipment in Shops, James Forrest. Am. Mach., vol. 50, no. 15, Apr. 10, 1919, pp. 699-701. Straight-line and contract-shop layout problems contrasted and cardboard models suggested.

Jigs and Tools

Jig and Tool Design—II, G. H. Hey. Machinery, vol. 13, no. 338, Mar. 20, 1919, pp. 704-708, 7 figs. Method of using drills and reamers in multispindle machine; standard wall handles, knurled nuts and index plungers.

Microscope

The Microscope in the Tool-room, John Scott. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 799-802, 6 figs. Its application to precision work on master plates and for cutting screw threads.

Milling

Continuous Rotary Milling—I & II, Edward K. Hammond. Machy. (N. Y.), vol. 25, nos. 8 and 9, Apr. and May 1919, pp. 687-694 and 842-846, 24 figs. Types of milling machines that operate without interruption; work-holding fixtures and methods of setting up parts to be milled.

Motors

Planning Efficient Motor Drives and Connections, G. B. Howe. Wood-Worker, vol. 38, no. 2, Apr. 1919, pp. 34-35, 6 figs. Examples of individual motor drive arrangements in wood-working plants.

Methods of Mounting Motors on Ceilings, Ralph G. Bradshaw. Can. Machy., vol. 21, no. 16, Apr. 17, 1919, pp. 373-375, 10 figs. Practice followed at various shops.

See also MECHANICAL ENGINEERING, Standards and Standardization (Standardized Parts Production).

MACHINERY, METAL-WORKING

Boring Heads

Tools for Boring Closed-Bottom Work. Machinery, vol. 13, no. 339, Mar. 27, 1919, pp. 735-736, 6 figs. Types of blades used in boring heads and methods of grinding and setting the blades.

Chuck, Spillman Automatic

Spillman Automatic Chuck (Mandrin à centrage automatique système H. Spillman). Génie Civil, vol. 74, no. 13, Mar. 29, 1919, pp. 251-254, 5 figs. Description of instrument; characteristic curves determined from measurements effected during actual performance.

Cylinder-Boring Machine

Quadruplex Cylinder Boring Machine. Engineering, vol. 107, no. 2779, Apr. 4, 1919, pp. 432-434, 7 figs. Model after French enclosed type.

Cylinder Boring and Reaming Fixtures, Franklin D. Jones. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 822-825, 11 figs. Designs of fixtures for locating and holding automobile engine cylinder castings during the boring and reaming operations.

Jigs

Jigs, Tools, etc., for the Production of Standardized Parts, Herbert C. Armitage. Engineer, vol. 127, no. 3300, Mar. 28, 1919, pp. 309-310, 1 fig., also Iron & Coal Trades Rev., vol. 98, no. 2665, Mar. 28, 1919, pp. 378-379, 2 figs., and Engineering, vol. 107, no. 2779, Apr. 4, 1919, pp. 434-437, 8 figs. Advantages derived by use of jigs and tools are claimed to be: interchangeability of work; cheapening of production; ability to use less skilled class of labor on manufacturing work. Effect of war conditions on engineering practice; curves showing relation between output and cost of components. Scheme for milling both ends of twenty connecting rods per hour.

Lathes

Italian Lathe for Gun Turning (Di un tornio Italiano per la lavorazione di pezzi d'artiglieria), Augusto de Marchi. Industria, vol. 33, no. 5, Mar. 15, 1919, pp. 136-143, 26 figs. Description of lathe specially designed for accurate work. Reference is made to tolerances permitted in manufacture of artillery parts.

Planers

Cincinnati Open-Side Planing Machines. Am. Mach., vol. 50, no. 16, Apr. 17, 1919, pp. 725-728, 6 figs. Among the points of interest cited are power rapid traverse for rail heads, box-type table, forced lubrication of the V's, patent "tu-speed" drive on 36-in. and 48-in. machines, quick-reverse aluminum pulleys and extra capacity table.

A Combination Machine Tool. Iron Age, vol. 103, no. 16, Apr. 17, 1919, pp. 1001-1003, 6 figs. Planer equipped with tool head and accessory parts designed for performing fundamental machining operations.

Thread-Cutting Machine

Thread-Cutting and Spindle-Boring Tools, J. H. Moore. Can. Machy., vol. 21, no. 16, Apr. 17, 1919, pp. 371-732, 4 figs. Description of standard lathe for precision thread cutting.

Tools, Forming

Tools for Automatic Machines, H. E. Thomas. Machinery, vol. 14, no. 340, Apr. 3, 1919, pp. 16-18, 13 figs. Types of forming tools; diagrams for determining diameter of forming tools. Read before Manchester Assn. of Engrs.

See also MECHANICAL ENGINEERING, Machine Shop (Gages and Tools).

MACHINERY, SPECIAL

Balancing Machines

Dynamic and Static Balancing. Machinery, vol. 14, no. 341, Apr. 10, 1919, pp. 40-44, 12 figs. Machines for balancing high-speed pulleys; aeroplane propeller static balancing machine; combination static balancing and drilling machine; "umbrella" type of balancing fixture. Second article.

Clutches

Automatic Clutch Design, M. H. Sabine. Machinery, vol. 14, no. 340, Apr. 3, 1919, pp. 1-5, 7 figs. Designed for controlling power unit from distant position. Clutch is electromechanically operated.

Designs

Developing Designs for Machinery and Tools. Machinery, vol. 13, no. 338, Mar. 20, 1919, pp. 690-691, 5 figs. Example of design evolution of two-wheel construction with traversing wheel slides.

Dividing Machines

Special Dividing Machines (Máquinas especiales para granduar), J. Y. Hunter. Ingenieria Internacional, vol. 1, no. 1, Apr. 1919, pp. 20-21, 8 figs. Type designed for circular division.

Portable Machinery

The Use of Portable Machinery in Ship Construction, G. F. Mackay. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 429-431, 9 figs. Features of electric caravan, winches, sawing machines, electric drills, and electric deck planers.

Tool Equipment

Principles of Special Machine Design, F. E. Johnson. Machy (N. Y.), vol. 25, no. 9, May 1919, pp. 797-798. Concerning tool equipment of manufacturing machines.

Thread-Milling Machine

Continuous Thread Milling Machine of Unusual Design, Edward K. Hammond. Machy. (N. Y.), vol. 25, no. 8, Apr. 1919, pp. 727-729, 3 figs. Description of machine designed for use in turning and threading bars of large diameter and indeterminate length.

See also CIVIL ENGINEERING, Building and Construction (House-Building Machinery); CIVIL ENGINEERING, Earthwork, Rock Excavation, etc. (Excavator, Tunneling), Roads and Pavements (Scarifier).

MACHINERY, WOODWORKING

Pattern-Turning Machine

Pattern Turning—I, Joseph A. Shely. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 836-841, 12 figs. Equipment required and methods used in turning.

MATERIALS OF CONSTRUCTION AND TESTING OF MATERIALS

Brass

Structural Characteristics of Rolled Sheet Brass, H. A. Eastick. Metal Indus., vol. 17, no. 4, Apr. 1919, pp. 176-178, 6 figs. Chart showing temperature at which recrystallization of alpha brass of different degrees of hardness commences.

Building Materials

Cheap Building Materials (Die Ausstellung "Sparsame Baustoffe" in der Austellungshalle am Zollogischen Garten), Zentralblatt der Bauverwaltung, vol. 38, nos. 102 and 103, Dec. 18 and 21, 1918, pp. 506-507 and 513-514, 6 figs. Describes exhibits shown at exhibition in Zoological Garden in Berlin, specially two types,—the "Vogt" concrete wall built of thin blocks of channel section interlocked and with certain interstices filled with cement grouting, and the "Ambi," built of thin concrete plates, with projecting ribs which interlock, the key being of cement grouting.

Cast Iron

Properties of Cast-Iron Test Bars, H. J. Young. Foundry Trade Jl., vol. 21, no. 207, Mar. 1919, pp. 157-160, 16 figs. Photomicrographs showing defects in test bars. Paper read before Newcastle Branch British Foundrymen's Assn.

Glues

Compositions of Glues (Diferentes composiciones de cola en la industria). Boletin de la Sociedad de Fomento Fabril, vol. 35, no. 12, Dec. 1918, pp. 834-840. Preparation of glues and allied productions for industrial purposes. (Concluded.)

Leather

Physical Examination of Leather and Leather Substitutes (Zur physikalischen Prüfung von Leder und Ersatzstoffen für Leder), R. Lauffmann. Kunststoffe, vol. 8, no. 8, Apr. 2, 1918, pp. 85-87, 3 figs. Examination regarding wearing qualities, tearing resistance, elongation, water absorption capacity, water permeation capacity and water resistance, and specific gravity.

Resistance of Materials

The Resistance of Materials—II, G. S. Chiles and R. G. Kelley. Ry. Mech. Engr., vol. 93, no. 4, Apr. 1919, pp. 181-184, 7 figs. Effect of sudden or abrupt changes in section on the distribution of unit stresses.

Steel

Dynamic Resistance of Steel (Sur la résistance dynamique de l'acier), Louis Roy. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 6, Feb. 10, 1919, pp. 304-307. Account of theoretical study and experimental verifications with gun bullets.

On the Elasticity of Steel, Akimasa Ono. Memoirs of the Coll. of Eng. Kyushu Imp. University, Fukuoka, Japan, vol. 1, no. 4, 1919, pp. 269-332, 18 figs. Experimental research; effect of elastic hysteresis on indication of load; temperature effect on deformation and effect of mechanical and thermal treatments on the constancy of elastic properties.

Wire Rope

Investigation of Wire Rope, J. H. Griffith. Eng. & Min. Jl., vol. 107, no. 17, Apr. 26, 1919, pp 737-738. Tests on wire ropes having diameter smaller than those of average mine hoisting ropes. Report by Bur. Standards, Pittsburgh.

MECHANICAL PROCESSES

Belt Shifter

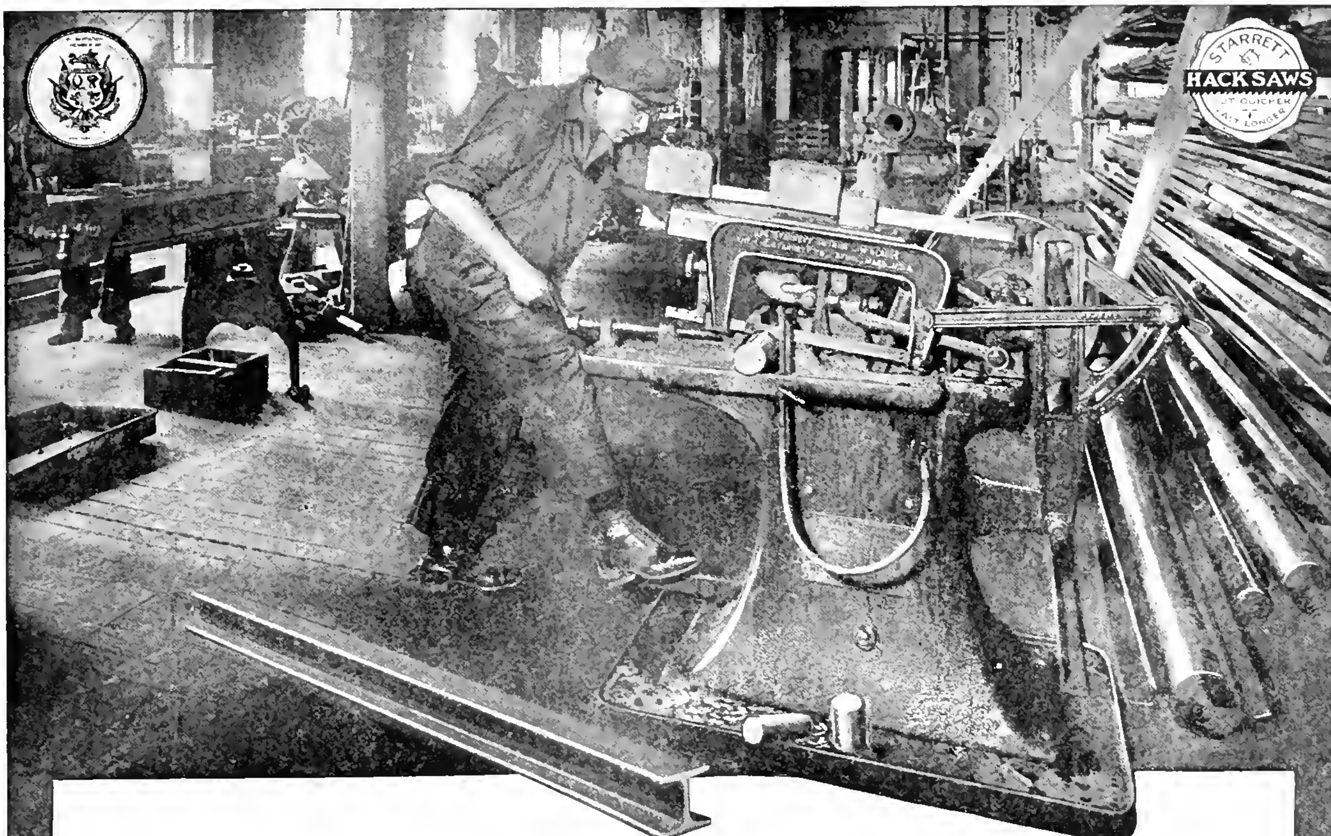
Manufacturing a Safety Belt Shifter, Robert Mawson. Am. Mach., vol. 50, no. 16, Apr. 17, 1919, pp. 743-745, 9 figs. Shifting mechanism consists of three rollers, one straight and two tapered; belt is pushed by means of straight roller, and owing to the shape of taper rollers the tendency is for the belt to slide onto the pulley as the shifter slides away.

Bending, Cold

The Bending and Forming of Brass Rod and Tubes, P. W. Blair. Metal Indus., vol. 17, no. 4, Apr. 1919, pp. 172-173, 5 figs. Machines for cold bending.

Boilers

How to Design and Lay Out a Boiler—VI, William C. Strott. Boiler Maker, vol 19, no. 4, Apr. 1919, pp. 103-106, 2 figs. Why the longitudinal seam must be stronger than the circumferential seam; formulæ for finding strength of boiler shell.



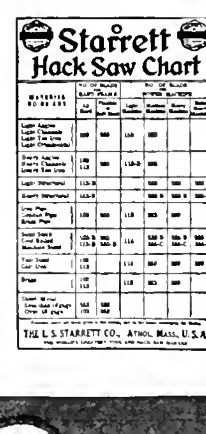
CHOOSE YOUR BLADE TO FIT YOUR WORK

If you've been cutting 3″ round machine steel with a heavy gage, coarse blade and find your next job is on structural beams—7″ I Beams, for instance—it's cheaper to change to a blade designed for that class of work than to keep on with the coarse blade you used on round stock.

If you use the same blade on both jobs, all the weight and strain of cutting the I Beam at any period in the cut must be borne by a smaller number of teeth than were engaged at any single instant on the round stock. The fewer the teeth that are cutting at any given time, the sooner they will become dull and the greater likelihood there is of their stripping.

That's *one* reason why the Starrett Hack Saw Chart recommends different kinds and shapes of metal. In this case, our tests show that a blade with more teeth to the inch should be used on structural steel than on round stock.

Follow the Starrett Hack Saw Chart LD and watch your cutting cost go down.



THE L. S. STARRETT COMPANY, Athol, Mass.

The World's Greatest Toolmakers
Manufacturers of Hack Saws Unexcelled

New York London Chicago

42-933

Starrett Hack Saws

Brass Rods

The Manufacture of Brass Rods—I & II. H. Mawson. Metal Industry, vol. 14, nos. 11 & 12, Mar. 14 & 21, 1919, pp. 203-207 and 229-232, 14 figs. Account of processes with reference to specification of Am. Soc. for Testing Materials. Paper read before Liverpool Eng. Soc.

Carburetors

Organization of a Carburetor Plant—I. Fred H. Korff. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 847-850. Functions of different departments and their relation to product.

Chains, Cast-Steel

Cast-Steel Anchor Chain. A. E. Crockett. Proc. Engrs. Soc. Western Pa., vol. 35, no. 1, Feb. 1919, pp. 1-25 and (discussion) pp. 26-30, 24 figs. Investigation and trials which finally led to adoption of present method of manufacturing cast-steel anchor chain, and account of dynamic tension tests of cast chains.

Chuck, Universal

Universal Chuck Manufacture. Machinery, vol. 14, no. 341, Apr. 10, 1919, pp. 33-39, 21 figs. Methods employed by A. A. Jones & Shipman, Leicester.

Crushers, Stone

Detroit United Railway Builds Large Stone Crusher Plant. Elec. Ry. Jl., vol. 53, no. 15, Apr. 12, 1919, pp. 726-727, 5 figs. Crushers taken from abandoned quarry used to equip plant of 500 cu. yd. per day capacity in salvaging waste materials for ballasting.

Earthenware

Earthenware (Fabricacion de articulos de arcilla o barro). Boletin de la Sociedad de Fomento Fabril, vol. 35, no. 12, Dec. 1918, pp. 825-829, 5 figs. Processes followed and machinery used in manufacture of earthenware.

Engines, Marine

Manufacture of Marine Engines at the Joshua Hendy Iron Works. H. S. Rexworthy. Metal Trades, vol. 10, no. 4, Apr. 1919, pp. 153-157, 10 figs. It is stated that engines weighing 100 tons and developing 2800 hp. are being delivered at the rate of one every 30 days.

Extrusion of Metals

The Present and Future of the Extrusion of Metals—I & II. A. E. Tucker and P. A. Tucker. Machinery, vol. 14, nos. 340 & 341, Apr. 3 and 10, 1919, pp. 29-30 and 47-48. Effect of a powerful deoxidizer on metal. Paper read before Birmingham Metallurgical Soc. Also abstracted in Ironmonger, vol. 166, no. 2366, Mar. 22, 1919, p. 79.

Gas Engines

The Manufacture of Marine Gas Engines. J. V. Hunter. Am. Mach., vol. 50, no. 17, Apr. 24, 1919, pp. 787-791, 20 figs. Manufacture of jigs and fixtures to adapt standard machine tools to rapid production of standard work in order to meet demands for powerful gas engines of comparatively light weight for marine and other powers.

Gear Cutting

Commercial Gear Cutting. W. Duckett. Machinery, vol. 13, no. 339, Mar. 27, 1919, pp. 723-725, 8 figs. Basis of machine cut gearing in engineering practice; particularly in manufacture of aero engine and automobile parts.

Hosiery Machine

Manufacturing the Banner Hosiery Machine, pts. II and III. Robert Mawson. Can. Machy., vol. 21, nos. 15 and 17, Apr. 10 and 24, 1919, pp. 345-348 and 391-394, 22 figs. Apr. 10: Operations performed on Jones and Lamson machines. Apr. 24: Operation of form milling sinker cams on Briggs milling machine; cutting raised cams; milling fashion cams and clutch cams.

Miller, Ford-Smith

Manufacturing the Ford-Smith Miller. J. H. Moore. Can. Machy., vol. 21, no. 12, Mar. 20, 1919, pp. 271-275, 9 figs. Concerning inspection methods involved.

Motor Parts

Making Liberty Aeroplane Motor Parts—I. Machinery, vol. 14, no. 340, Apr. 3, 1919, pp. 8-13, 13 figs. Methods employed in machining cylinder inlets and exhaust elbows.

Pressed Steel, Reinforcing

Making Pressed-Steel Reinforcing. Iron Trade Rev., vol. 64, no. 17, Apr. 24, 1919, pp. 1073-1080, 16 figs. How various shapes of beams, plates, studs, concrete bars, etc., are adapted for building purposes.

Roller Bearings

Making the Timken Roller Bearing—I. Edward K. Hammond. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 829-835, 13 figs. Methods of heat-treating, machining and inspecting.

Rubber Goods

Railroad Rubber Goods. G. W. Alden. Official Proc. Car Foremen's Assn. of Chicago, vol. 14, no. 6, Mar. 1919, pp. 65-100. Classification of various goods according to process of manufacture, together with exposition of recent developments of rubber industry.

Sanding Machine

Building a Sanding Machine. Robert Mawson. Machy. (N. Y.), vol. 25, no. 8, Apr. 1919, pp. 738-742, 15 figs. Methods of machining parts of a sanding machine; describing jigs and fixtures used and general procedure in assembling.

Steel Mills

Westinghouse Electric Blooming-Mill (Train blooming à Commande électrique système Westinghouse). Génie Civil, vol. 74, no. 12, Mar. 22, 1919, pp. 225-228, 7 figs. Scheme of a. c. instalation developed by British Westinghouse Co. From Engineer, Dec. 13, 1918.

Large Rolling-Mill Plant. Electrical Review, vol. 84, no. 2157, Mar. 28, 1919, pp. 340-342, 7 figs. Electrical equipment for a 38-in. reversing cogging mill designed to roll 3-ton steel ingots 18 x 22 in. to 4 x 4-in. billets, with an output of 60 tons per hour. (Concluded.)

See also ELECTRICAL ENGINEERING, *Power Applications (Mill Drive).*

Tractors

Turning Out 100 Tractors per Day. P. M. Heldt. Automotive Industries, vol. 40, no. 15, Apr. 10, 1919, pp. 788-792, 7 figs. Machining and assembling methods employed at Milwaukee plant of Int. Harvester Co. (To be continued.)

Westinghouse Marine System

Building the Westinghouse Marine System. Edward K. Hammond. Machy. (N. Y.), vol. 25, no. 9, May 1919, pp. 789-796, 16 figs. Operations involved in forging, machining, assembling and testing various parts of equipment.

MEASUREMENTS AND MEASURING APPARATUS

Calorimeter

An Improved Form of Throttling Calorimeter. W. R. Woolrich. Power, vol. 49, no. 12, Apr. 1, 1919, pp. 495-496, 2 figs. Explains how instrument may be made self-contained by having necessary curves drawn on a metal plate fastened to barrel or calorimeter.

Clinometer

A Useful Instrument. H. L. Seymour. Can. Engr., vol. 36, no. 13, Mar. 27, 1919, pp. 335-337, 2 figs. Abney Hand level, pocket altimeter or clinometer and its uses in surveying, engineering and architectural work.

Coal Meters

A Coal Meter for Boilers. Engineer, vol. 127, no. 3298, Mar. 14, 1919, p. 261, 2 figs. Lea recorder intended for boilers fitted with chain grates; similar in operation to the well-known V notch recorders and integrators for water measurement.

Colorimeter

The Numerical Expression of Color Properties. Paul H. Geiger. Michigan Technic, vol. 32, no. 1, Mar. 1919, pp. 36-40, 2 figs. Principle upon which Nutting colorimeter operates.

Flow in Pipes, Fluid

Electrical Measurement of Fluid Flow in Pipes. Jacob M. Spitzglass. Mech. Eng., vol. 41, no. 5, May 1919, pp. 429-432 and 487, 6 figs. Theory and development of device embodying ammeter and watt-hour meter in which the electric current flowing is proportional to the quantity of fluid passing through pipe.

Hardness Tests

Hardness Tests of Gun-Barrel Steel. William Kent Shepard. Am. Mach., vol. 50, no. 16, Apr. 17, 1919, pp. 739-742, 2 figs. Ultimate strength, yield point, Brinell and scleroscope hardness number. Percentage reduction in area and elongation in 2-in. Brinell diameter and scleroscope hardness number.

Indicating Instruments, Residence of

The Concept of Resilience with Respect to Indicating Instruments. Frederick J. Schlink. Jl. Franklin Inst., vol. 187, no. 2, Feb. 1919, pp. 147-169, 2 figs. Deals particularly with instruments of index-and-scale and value-controlling types of class of non-integrating instruments, as distinguished from integrating instruments and those used for comparison purposes strictly.

Microscope

Usefulness of the Metallurgical Miscroscope to the Engineer. E. D. Fahlbarg. Wisconsin Engr., vol. 23, no. 7, Apr. 1919, pp. 255-257, 4 figs. Examples of its uses in examination

Pyrometers

Standards of Temperature and Means for Checking Pyrometers. Jl. Am. Steel Treaters Soc., vol. 1, no. 3, Dec. 1919, pp. 99-110, 7 figs. A consideration of sources of error in thermocouple pyrometers leads writer to advise that in order to secure reliable measurements in plant turning out high-grade heat-treated product, following equipment should be available: Standard precision and double range potentiometers with accessories, one mounted and two unmounted platinum thermocouples, checking furnace with control panel and extra standard cell.

Scale Conversion

Conversion of Uneven into Even Scales (Die Umwandlung einer ungleichmäßigen Teilung in eine gleichmässige), Hugo Krüss. Zeitschrift für Instrumentenkunde, vol. 38, no. 12, Dec. 1918, pp. 195-200, 6 figs. Conversion effected by means of two equal bars hinged at one end and constrained to move at the other along a straight line reproducing both scales. When hinged end is moved along a curve, the shape of which depends on nature of uneven scale, the other ends point at corresponding values in the scales.

Steam Generation

Determining Economy of Steam Generation. G. H. Sheasley. Power Plant Eng., vol. 23, no. 9, May 1, 1919, pp. 395-397. Methods of procedure and equipment required.

Temperatures, Low

The Measurement of Low Temperatures with Thermocouples. Thomas Spooner. Jl. Franklin Inst., vol. 187, no. 4, Apr. 1919, pp. 509-511, 2 figs. Chromel-alumel thermocouple for measuring temperatures below 0 deg. cent.

Thermometer, Mercury, Testing

Simple Boiling Point Apparatus for Testing Mercury Thermometers at Temperatures over 100 deg. C (Ein einfacher Siedepunktapparat zur Prüfung von Quecksilberthermometern bei Temperaturen über 100 deg. C.), Gottfried Dimmer. Zeitschrift für Instrumentenkunde, vol. 38, no. 3, Mar. 1918, pp. 33-40, 2 figs. Describes tests with thermoelement and mercury thermometer and results: Substances used were aniline of 184.1 deg.; naphthaline at 218 deg.; benzophenone at 306 deg.; and sulphur at 444.6 deg.

Turbo-Alternators, Efficiency

The Determination of the Efficiency of the Turbo-Alternator. S. F. Barclay and S. P. Smith. Engineer, vol. 127, no. 3299, Mar. 21, 1919, pp 290-291, 2 figs. Determination from measurements of the cooling air and by the "air-heating" method.

Water Level, Distant

Measuring Distant Water Levels. C. G. Brown. Electricity, vol. 33, no. 1482, Apr. 4, 1919, pp. 201-202, 3 figs. Instrument employs relay connected to solenoid resistance in which contact placed alongside is controlled by height of river by means of float. Suitable arrangement records motions of float at hydraulic station.

Water-Waste Testing

Devices for Water-Waste Surveys at Oak Park, Illinois. Eng. News-Rec., vol. 82, no. 17, Apr. 24, 1919, pp. 829-831, 2 figs. Portable venturimeter to test pipe districts with pitometer inserted in house service.

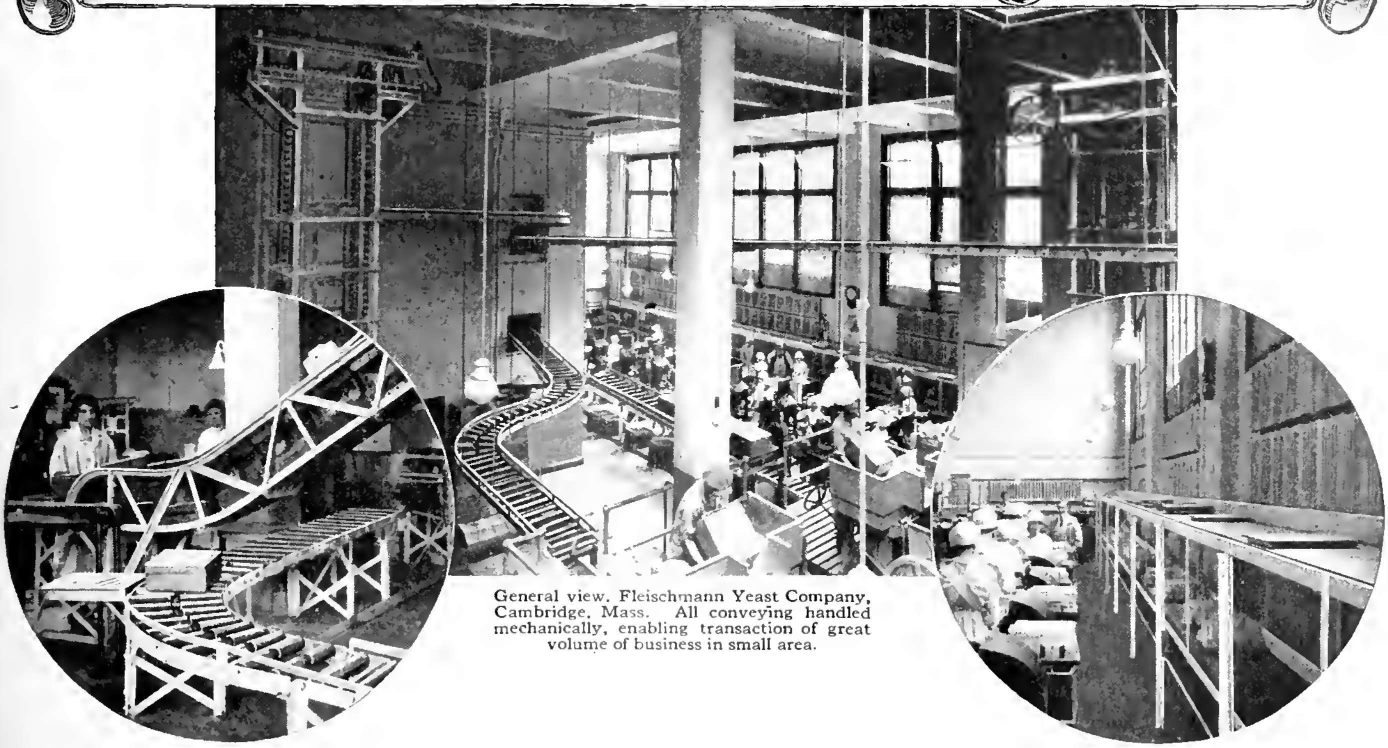
See also ELECTRICAL ENGINEERING, *Measurements and Tests (Temperature Determination by Weighing, Timing).*

MECHANICS

Articulated Rods

The Articulated Rod. T. L. Sherman. Automobile Eng., vol. 9, no. 125, Apr. 1919, pp 102-106, 16 figs. Formulæ for various mechanical quantities and inertia forces curves on articulated-rod system in which two cylinders are fixed in one plane at a certain angle.

Lamson Conveyors



General view. Fleischmann Yeast Company, Cambridge, Mass. All conveying handled mechanically, enabling transaction of great volume of business in small area.

Empty boxes descending chute from shipping-platform to wrapping-machines; loaded boxes carried by conveyor to storage.

Belt conveyors (at side) bringing yeast to wrapping-machines.

100% CONVEYING SERVICE

In planning a conveying system, it is necessary to consider the nature of the product—its texture, liability to damage, etc.; the nature of the receptacles in which the product must be carried; the points to and from which the conveying is to be done; the different levels to be joined; the quantity of the flow of product and also the periodicity of the flow.

Yeast is delicate stuff to handle, and this factory called for an automatic pick-up, hoisting and delivering without danger of jar or collision.

The Lamson System is performing this delicate function perfectly. Tons of yeast are carried throughout the section of the factory shown and are not out of the ice-box long enough to lose the chill.

The yeast comes from the ice-box in 80-pound cases to the mixing-machine, where it is molded. Then a conveyor carries it automatically to the wrapping-machine, where it is either packed in boxes, or piled five or six inches high on pallets and automatically delivered back to the ice-box without jar, disarrangement or disturbance to the slippery cakes.

Write for book on Conveying illustrating the versatility of the Lamson System for carrying things—delicate and rough, small and large, light and heavy.

Beams

Economical Sections of Simple Reinforced-Concrete Beams (Recherche des sections economiques des poutres simples en béton armé travaillant à la flexion), G. Guillaumin. Génie Civil, vol. 74, no. 13, Mar. 29, 1919, pp. 249-251. Proposes simplification of calculation and formulæ which have appeared in Eng. News, Feb. & June 1907, and in Technique Moderne, Jan. 1910.

Distribution of Metal in Beams and Levers, Eugene Motchman. Scale Jl., vol. 5, no. 7, Apr. 10, 1919, pp. 13-14, 7 figs. Application of design and formulæ to beams used in scales.

Elastic Stresses

Strains due to Temperature Gradients, with Special Reference to Optical Glass, Erskine D. Williamson. Jl. Wash. Acad. Sciences, vol. 9, no. 8, Apr. 19, 1919, pp. 209-217, 1 fig. General equations for elastic stresses produced by temperature differences in spheres, cylinders and slabs when the temperature distribution is symmetrical about the center axis or central plane, respectively. More specific equations are given for the case of temperature distribution due to uniform surface heating.

Frames

Analysis and Tests of Rigidly Connected Reinforced Concrete Frames, Mikishi Abe. University of Illinois Bul. no. 107, vol. 16, no. 8, Oct. 21, 1918, 106 pp., 59 figs. Formulæ for moments and other indeterminate quantities for several types of indeterminate structures. Formulæ have been derived by methods involving use of principle of least work, and their applicability and reliability were tested in frames designed according to them.

Irregularity, Coefficient of

Coefficient of Irregularity of Steam Engines, Gas Engines and of Electric Generators Running in Parallel (Coefficient d'irregularité des machines à vapeur, moteurs à gaz et marche en parallèle de génératrices électriques), M. Barrusta. Industrie Electrique, vol. 28, no. 642, Mar. 25, 1919, pp. 104-109. Formulæ developed from assumption that flywheel possesses two motions, one uniform and one pendular; in the case of electric generators motion is considered as resulting from action of two couples and its regularity is expressed in terms of a parameter in the differential equation of motion.

Pendulum

Note on the Motion of a Simple Pendulum after the String has Become Slack, W. B. Morton. London, Edinburgh and Dublin Phil. Mag., vol. 37, no. 219, Mar. 1919, pp. 280-284, 1 fig. Finds from graphs constructed from theoretical considerations that ultimate motion approaches asymptotical to oscillation between ends of horizontal diameter.

Shafts, Critical Speed of

Critical Speed in Tapered Shaft Design. Machinery, vol. 13, no. 338, Mar. 20, 1919, pp. 694-695, 1 fig. Diagram for determining critical speed of tapered shafts.

Shafts, Whirling Speed of

The Lateral Vibration of Loaded Shafts in the Neighbourhood of a Whirling Speed—the Effect of Want of Balance, H. H. Jeefcott. London, Edinburgh and Dublin Phil. Mag., vol. 37, no. 219, Mar. 1919, pp. 304-314, 4 figs. Discusses how want of balance causes so-called "whirling speeds" and to what extent it is practical to carry balancing.

Springs

Thermodynamics of Springs (Zur Thermodynamik der Federn), H. Bock. Zeitschrift für Instrumentenkunde, vol. 38, no. 7, July 1918, pp. 109-115, 3 figs. Method evolved after *p-r* diagram of Gast theory for presenting thermal processes; application of method to theory of springs makes it possible at least partly to calculate "elastic after effect" by means of entropy theorem.

A New Theory of Plate Springs—III, David Landau and Percy H. Parr. Jl. Franklin Inst., vol. 187, no. 2, Feb. 1919, pp. 199-213, 3 figs. On "nip" stresses and "life" of plates under varying stresses produced in metal when in use.

See also CIVIL ENGINEERING, Cement and Concrete (Beams).

MOTOR-CAR ENGINEERING

Aluminum

The Why of Aluminum in Motor Cars, H. M. Taylor. Motor Age, vol. 35, no. 16, Apr. 17, 1919, pp. 7-9, 3 figs. Feature of 8-cyl. engine built almost entirely of aluminum; welding and machining aluminum parts.

Brake Levers

Determining Correct Location of Brake Levers, Walter C. Baker. Automotive Industries, vol. 40, no. 17, Apr. 24, 1919, pp. 914-917, 6 figs. Attempts to show how braking action may be remedied by changing their loads and their location. Maintains that brakes are not to blame for pedal motion due to torque and spring action.

Benzol

Benzole as a Motor Fuel, Eric W. Walford. Autocar, vol. 42, no. 1223, Mar 29, 1919, pp. 439-441, 2 figs. Hints concerning its use, either by itself or mixed with petrol.

Design

Progressive and Retrogressive Designing, Otto M. Burkhardt. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 216-226, 15 figs. Technical considerations on elimination of certain links and members in design of motor vehicle. Elimination of torque and radius rods is one of various examples considered.

Probable Effect on Automobiles of Experience with War Airplanes, O. E. Hunt. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 243-245. Holding improvements in airplane engines not suitable for cars, writer believes that the most important contribution which the airplane has made to the automobile is stimulus to thought of industry as a whole that has resulted from study of design and manufacturing problems.

Engines

Possible Effect of Aircraft Engine Development on Automobile Practice, Henry M. Crane. Jl. Soc. Automotive Engrs., vol. 4, No. 4, Apr. 1919, pp. 240-242. Writer does not expect any radical change in automobile design, but only a probable increase in number of "valve-in-the-head" engines.

European Cars

Post-War Cars Designed by Europe, W. F. Bradley. Motor Age, vol. 35, no. 15, Apr. 10, 1919, pp. 24-27, 11 figs. Comparison of types shown at Lyons fair with American models.

The Angus Sanderson Car. Automotive Industries, vol. 40, no. 17, Apr. 24, 1919, pp. 888-890, 6 figs. Embodies engine with slipper-type piston, counterbalanced crankshaft, integral cylinder block and top half of crankcase, and forced-feed lubrication.

Automotor Design and Construction of 1919. Auto, vol. 24, no. 15, Apr. 10, 1919, pp. 360-364, 8 figs. Mechanical arrangement of the 16-hp. Panhard.

A New British Quantity-Production Car. Automotive Industries, vol. 40, no. 15, Apr. 10, 1919, pp. 807-808, 4 figs. Austin 20-hp. open touring car.

A New Eight-Cylinder Piccard-Pictet. Autocar, vol. 42, no. 1223, Mar. 29, 1919, pp. 432-434, 7 figs. Franco-Swiss high-powered car. Features are front-wheel brakes and single sleeve-valve V engine.

The 20-25 Hp. Six-Cylinder Straker. Autocar, vol. 42, no. 1223, Mar. 29, 1919, pp. 429-431, 5 figs. Car with engine having separate cylinders, aluminum pistons, and overhead valve-operating mechanism.

Kerosene Burning

Paraffin as Fuel, Harry R. Ricardo. Automobile Engr., vol. 9, no. 122, Jan. 1919, pp. 2-5, 5 figs. Principle of utilization; type of carburetor required; results of tests.

Lubrication

The Lubrication of Motor Cars, G. W. A. Brown. Automobile Engr., vol. 9, no. 125, Apr. 1919, pp. 110-115, 34 figs. Suggests improvement in oiling of gear box, universal joints, live axle, steering gear and other components of chassis. Paper read before Instn. Automobile Engrs.

State Regulation

Regulation of the Speed, Weight, Width and Height of Motor Trucks and Trailers, George Graham. Can. Engr., vol. 36, no. 6, Feb. 6, 1919, pp. 200-202. Plan of Am. Assn. of State Highway Officials for uniform truck laws.

Steam Cars

The Clarkson Steam Chassis, Type IX. Automobile Engr., vol. 9, no. 122, Jan. 1919, pp. 17-21, 12 figs. Four-cylinder tandem compound engine, with coke as fuel.

Temperature Control

Controlling the Water Temperatures, Eric W. Walford. Autocar, vol. 42, no. 1224, Apr. 5, 1919, pp. 471-473, 5 figs. Methods for increasing thermal efficiency and ease of starting and for promoting vaporization of fuel, by regulating effective radiating surfaces.

Tires, Rubber-Substitute

Substitute for Rubber Tires (Ersatz für Kautschukreifen), II. Jahr. Kunststoffe, vol. 8, nos. 14 & 15, Jul. 2, and Aug. 1, 1918, pp. 157-160 and 173-175, 26 figs. Substitutes used are principally leather, all kinds of woven materials, felt, paper, vegetable fibers, hair, bristles, etc. Various types of tires and methods of fastening them to rim are described.

Notes on German Mechanical Transport, G. F. Randall. Motor Traction, vol. 28, no. 736, Apr. 9, 1919, pp. 305-307, 5 figs. Tires substituted by device consisting of hardwood blocks let into rims of ordinary steel or artillery wheels and held in place by split steel bands bolted up on each side of blocks in such a way as to render the wooden tires easily removable.

Tires, Truck

Pneumatic Tires on Trucks, B. B. Bachman. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 298-302. Advantages claimed for pneumatic tires are reduction in mechanical repairs, increase in permissible speed, decrease in gasoline and oil consumption, less fatigue for men, lessened depreciation of roads and greater tractive ability.

Tractors

Twin City 12-20 Kerosene Tractor, P. M. Heldt. Automotive Industries, vol. 40, no. 16, Apr. 17, 1919, pp. 836-839, 5 figs. Three-plow tractor with double intake and exhaust valves, enclosed drive, pressure lubrication, thermostatic temperature control, backbone frame construction and front-spring suspension.

The Velie Biltwell Tractor, P. M. Heldt. Automotive Industries, vol. 40, no. 15, Apr. 10, 1919, pp. 799-804, 15 figs. Three-plow machine with kerosene-burning engine, 3-speed sliding-gear transmission and inclosed bull-gear drive.

Trucks, 4-Wheel Drive

Special Parts for Four-Wheel Drive Trucks, Harry C. Satterthwaite. Am. Mach., vol. 50, no. 15, Apr. 10, 1919, pp. 691-698, 21 figs. Operations on ball-and-socket joint placed on each end of front axle. Truck is both steered and driven in front.

War Experience

Touring Cars on War Service. Automobile Engr., vol. 9, no. 122, Jan. 1919, pp. 13-16, 3 figs. Notes on performance of lighter transport chassis.

Motor-Lorry Design. Times Eng. Supp., vol. 15, no. 533, Mar. 1919, p. 103. Lessons of war service.

See also RAILROAD ENGINEERING, Locomotives (Gasoline-Electric Locomotive), Operation and Management (Road Motor Vehicle Department); ELECTRICAL ENGINEERING, Ignition Apparatus; MECHANICAL ENGINEERING, Internal-Combustion Engines.

PIPE

Layout

A Problem in Piping Layout, James Leslie Lane. Boiler Maker, vol. 19, no. 4, Apr. 1919, p. 93, 1 fig. Mathematical computation of angles and lengths of lines.

Piping

Piping and Pipe Fittings. Southern Engr., vol. 31, no. 2, Apr. 1919, pp. 36-50, 17 figs. Calculations, layout, sizes, bends, traps, and other arrangements of piping.

POWER GENERATION

California

Water Power in California, Andrew H. Palmer. Sci. Am. Supp., vol. 87, no. 2260, Apr. 26, 1919, pp. 260-261 and 271, 4 figs. Factors on which it depends and the extent to which it might be utilized.

Canada

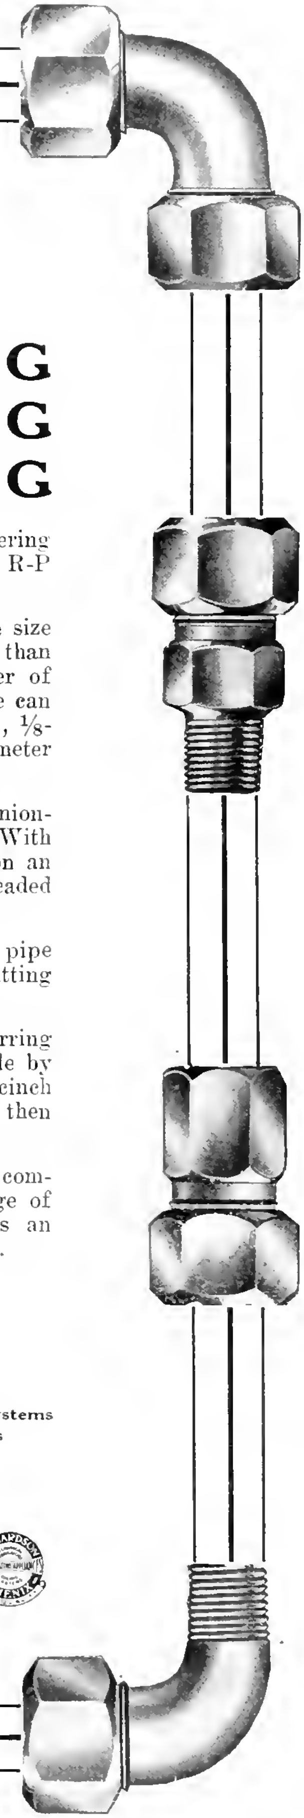
The Present Electrical Outlook in Canada, A. S. L. Barnes. Electrical Review, vol. 84, no. 2159, Apr. 11, 1919, pp. 421-423. Councils furthering British electrical trade with Canada. (Concluded.)

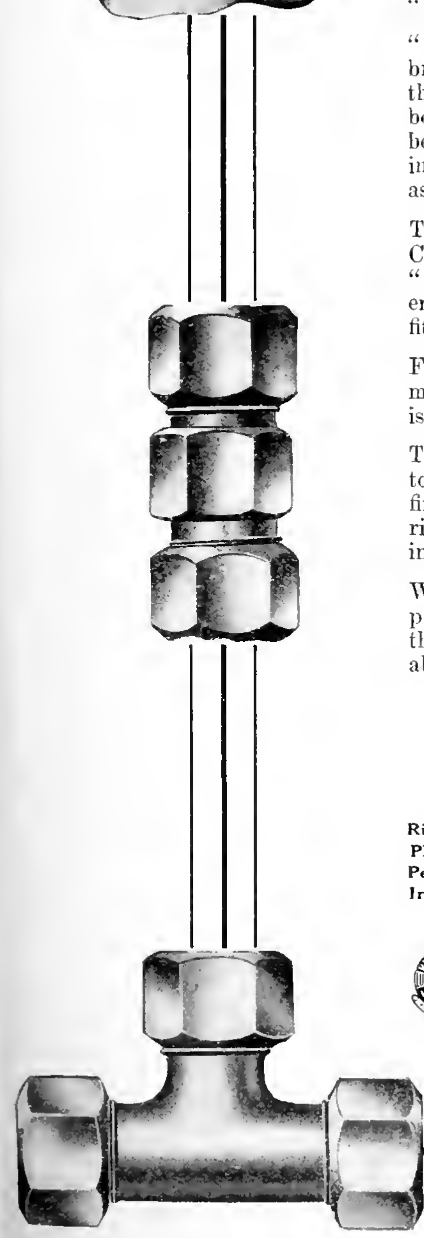
Coquitlam Buntzen

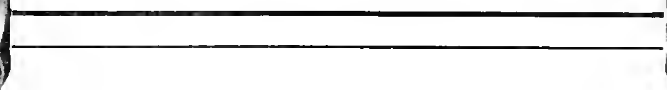
The Coquitlam Buntzen Hydro-Electric Plant, F. C. Perkins. Power House, vol. 13, no. 4, Apr. 5, 1919, pp. 83-86, 5 figs. Originally designed for 12,000 hp., plant has grown to 85,000 hp. Growth of project is described and capabilities of economically developing 750,000 hp. are examined.

Eastern States

Hydro-Electric Development in Eastern States, D. H. Colcord. Power Plant Eng., vol. 23, no. 8, Apr. 15, 1919, pp. 362-364, 4







NO THREADING SOLDERING FLARING

Oil-tight joints can be easily made without threading, soldering or flaring out the ends of the pipe or tubing by using R-P "Union Cinch" Fittings.

"Union Cinch" fittings are made to fit standard iron pipe size brass or steel tubing. Tubing has a larger inside diameter than the same size standard pipe, although the outside diameter of both are the same. Therefore when tubing is used, the size can be reduced one size smaller all around. As an illustration, ⅛-inch drawn steel tubing has practically the same inside diameter as ¼-inch iron pipe size pipe.

The only tools necessary to install an oil line with "Union-Cinch" fittings are a hack saw, file, and monkey wrench. With "Union-Cinch" fittings the oil pipe lines can be installed on an engine in one-half the time needed when ordinary threaded fittings are used.

Furthermore, every "Union-Cinch" fitting being a union, pipe may be taken down and put together at any point where a fitting is inserted.

These fittings will be more thoroughly understood by referring to the sectional view shown above. The connection is made by first slipping the union nut "4" and then the soft-brass cinch ring "1," over the end of the tubing "2." The tubing is then inserted into the fitting up against shoulder "3."

When the nut "4" is drawn up, the cinch ring "1" is compressed in such a manner as to grip the pipe on each edge of the ring at "5-5," making a double-cinch, which insures an absolutely tight joint that will not shake loose or come out.

Write for Bulletin C-30 describing "Union-Cinch" Fittings and other accessories for Automatic Oil Circulating and Filtering Systems.

WE MANUFACTURE

Richardson Sight Feed Oil Pump
Phenix Mechanical Lubricator

[illegible] Portsmouth Nameplates, [illegible] and [illegible]

Gas and Electricity

Distribution of Heat, Light and Motive Power by Gas and Electricity, Dugald Clerk. Colliery Guardian, vol. 117, no. 3039, Mar. 28, 1919, pp. 713-714. Theoretical efficiency of estimated average performances of gas works and of electric undertakings of United Kingdom. Paper read before Roy. Soc. of Arts.

Illinois

Independent Illinois Power System. Power Plant Eng., vol. 23, no. 9, May 1, 1919, pp. 391-393, 5 figs. Abbott Light & Power Co.'s 45 miles of line supplying lighting and power load of 400 kw. to ten towns.

Interconnection

Interconnection Reduces Steam Reserve Necessary, L. J. Moore. Elec. World, vol. 73, no. 17, Apr. 26, 1919, pp. 840-842, 4 figs. Results obtained by tying together power systems in Central California.

Muscle Shoals

Features of Muscle Shoal Station, Edward R. Welles and W. A. Shoudy. Elec. World, vol. 73, no. 15, Apr. 12, 1919, pp. 729-732, 4 figs. Characteristics of power-plant, particularly boiler, furnace, stoker, condensers and auxiliaries.

Pittsburgh District

Power Production for Electrochemical Purposes, C. S. Cook. General Meeting Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 10, pp. 167-171. Cost in Pittsburgh district, particularly when generated in large stations and when off-peak power is used for electrochemical and electrometallurgical purposes. Writer concludes that this kind of steam power can compete with water power in all except the most favorable cases for developing hydraulic power.

State Aid

State Aid for Water Power Development, Alfred M. Beale. Can. Engr., vol. 36, no. 13, Mar. 27, 1919, pp. 333-334. Complete ownership by Government is not considered essential, but it is suggested that Government furnish capital and control rates.

Swift Rapids Plant

Electric Power from Swift Rapids Plant. Elec. News, vol. 28, no. 7, Apr. 1, 1919, pp. 27-31, 9 figs. Combination generating plant and ship lift lock.

POWER PLANTS

Boiler Mountings

Boiler Mountings. Mar. Engr. & Naval Architect, vol. 41, no. 499, Apr. 1919, pp. 210-214, 5 figs. Blow-out apparatus. (Continued.) Paper read before Liverpool Eng. Soc.

Boiler Room

Saving Coal in the Blackstone Power Plant, W. A. Eberman. Power, vol. 49, no. 17, Apr. 29, 1919, pp. 632-634, 3 figs. Remodeling of boiler furnaces together with coöperation of operating force and intelligent use of instruments is said to have resulted in saving fuel amounting to 12 per cent.

Clinker Grinders

The Clinker Grinder in Modern Boiler Practice, Charles H. Bromley. Power, vol. 49, no. 16, Apr. 22, 1919, pp. 592-598, 12 figs. Describes various grinders and gives their performance data as obtained in different installations.

Condensers

Surface Condensing Plant for Large Power Stations, R. J. Kaula. Electrical Review, vol. 84, no. 2160, Apr. 18, 1919, pp. 453-455 and discussion pp. 455-456, 2 figs. Graph showing [illegible] of free air at atmospheric pressure against plant capacity in 1000 lb. of steam per hour, arrangement of strainers and pumps on [illegible] Paper read before Instn. Elec. Engrs.

Economizers

Proportioning Fuel Economizers, A. E. Clark. Power, vol. 49, no. 16, Apr. 22, 1919, pp. 613-615, 5 figs. Data showing advantages of contraflow over parallel flow of water and gas.

Equipment

Modern Steam Power Station Equipment, Joseph G. Worker. Coal Indus., vol. 2, no. 4, Apr. 1919, pp. 157-163, 13 figs. Review of equipment installed in various power plants.

Governor

An Electrically Operated Steam Engine Governor, G. T. Garwood. Model Engr. & Elecn., vol. 40, no. 936, Apr. 3, 1919, pp. 234-236, 2 figs. A throttle actuating solenoid is switched in and out by a centrifugal device similar to an ordinary shaft governor.

Oil Filters

Reducing Cost of Production by Saving Coal and Oil (Die Verminderung der Betriebskosten durch Ersparnisse an Kohlen und Oel), Otto Grunner. Kunststoffe, vol. 8, no. 8, Apr. 2, 1918, pp. 88-92, 10 figs. Recommends counter current preheaters as efficient in reducing coal consumption and repair work, and suggests installation of oil filter for steam in order to prevent oil particles from getting into pipe system, thereby reducing efficiency of preheater.

Stand-By Operation

Converting a Steam Plant to Stand-by Operation, L. M. Klauber. Jl. Electricity, vol. 42, no. 8, Apr. 15, 1919, pp. 353-357, 3 figs. Problems met in turbine and boiler rooms. From report of Eng. Committee for Spring Convention of Pac. Coast Section N. E. L. A.

Stokers

Influence of Chemistry upon Improvement in Stoker Design, Clyde H. McClure. Elec. Rev., vol. 74, no. 16, Mar. 19, 1919, pp. 620-621. States that from viewpoint of chemical engineer future improvement in mechanical stokers, specially for territory dependent upon Indiana and Illinois coal, lies in combination of chain-grate and underfeed types.

Turbines

United States Nitrate Plant No. 2 at Muscle Shoals, Charles H. Bromley. Power, vol. 49, nos. 13 and 15, Apr. 1 & 15, 1919, pp. 482-488 and 558-561, 14 figs. Description of triple cylinder, pure-reaction, parallel-flow turbine; 60,000-kw. unit has four condensers, each of 25,000 sq. ft. of Muntz-metal tube surface.

Turbo-Generators

Narragansett Company Installs 45,000-kw. Turbo-Generator, J. P. Rigsby. Power Plant Eng., vol. 23, no. 8, Apr. 15, 1919, pp. 349-353, 3 figs. Installation is of cross-compound double-unit type, consisting of a high- and a low-pressure unit, each connected through a flexible coupling to its own generator.

Valves and Fittings

Valves and Fittings in Marine Work, A. G. Christie. Shipping, vol. 7, no. 2, Apr. 12, 1919, pp. 19 and 22. Comments on marine practices from viewpoint of central station man. Paper presented before Baltimore Section, Am. Soc.Mech.Engrs.

Water Treatment

Principles of Boiler Water Treatment. Ry. Rev., vol. 64, no. 14, Apr. 5, 1919, pp. 547-549. Origin, effects and means of removing scale; processes and economies of water treatment.

Boiler Water Treatment. Dept. of the Interior, Bur. of Mines, tech. paper 218, 1919, 8 pp. How a reduction in heat losses may be effected through substitution of softened for hard boiler water. Reprint of Eng. Bul. no. 3, prepared by U. S. Fuel Administration.

See also CIVIL ENGINEERING, Water Supply (Softening); MECHANICAL ENGINEERING, Standards and Standardization (Turbo-Generators).

POWER TRANSMISSION

See ELECTRICAL ENGINEERING, Power Applications (Mill Drive); MECHANICAL ENGINEERING, Machine Shop (Motors).

PRODUCER GAS

Gas-Producer Plant

Details of Operation of a Gas Producer Plant, J. S. McClimon. Gas Age, vol. 43, no. 8, Apr. 15, 1919, pp. 421-423, 4 figs. Recommendations to operators and superintendents.

PUMPS

Cost of Pumping

Cost of Pumping Through Pipe Lines, G. C. Habermeyer. Can. Engr., vol. 36, no. 17, Apr. 24, 1919, pp. 402-403. Table showing cost in dollars per mile per million U. S. gal. of pumping water at various rates through different sizes of cast iron pipe lines.

Pumping Station Design

Design of New Electric-Drive Water-Pumping Station was Governed by Power Rate, Henry W. Taylor. Eng. News-Rec., vol. 82, no. 14, Apr. 3, 1919, pp. 653-655, 2 figs. Water consumption change in power, power rates and changes in design involved in development of pumping station of water works at Cohoes, N. Y.

Pumping Station, Distribution

Vergennes Pumping Station, Henry W. Taylor. Fire & Water Eng., vol. 65, no. 18, Apr. 30, 1919, pp. 984-985, 4 figs. System of distribution.

Submersible Pumps

Submersible Salvage Pumps and Engines. Engineer, vol. 127, no. 3299, Mar. 21, 1919, pp. 274-275 & 278, 9 figs. Means adopted to permit ability of engines to withstand submergence in water are: Every part of mechanism is arranged inside trunk of crank-case and those parts which protrude are of robust construction; all openings, such as inlet and exhaust are provided with easily attached covers, which prevent water from getting into interior of engine.

REFRACTORIES

Zirconia

Zirconia: Its Utilisation as a Refractory Substance, an Opacifier, and an Abrasive, M. A. Granger. Chemical News, vol. 118, nos. 3073 and 3074, Mar. 7 and 14, 1919, pp. 115-118 and 121-123. Mar. 7: Chemical nature of zirconiferous minerals. Mar. 14: Experiments on extraction of zirconia by alkaline carbonate.

REFRIGERATION

Absorption System

Mechanical Refrigeration—III. Southern Engr., vol. 31, no. 2, Apr. 1919, pp. 54-57, 2 figs. Diagram of absorption system and direction diagram showing course of gas and aqua ammonia.

Ammonia Compression

Economical Ammonia Compression, A. G. Solomon. Power Plant Eng., vol. 23, no. 8, Apr. 15, 1919, pp. 370-373. Advises stopping of leaks and regulating pressures.

Compression Refrigerating Machine

The Compression Refrigerating Machine, Gardner T. Voorhees. Ice & Refrigeration, vol. 56, no. 4, Apr. 1919, pp. 257-259. Operation of water and steam cycle; general comparison of refrigerants. (Continuation of serial.)

The Ammonia Compression Refrigerating System—XXIX, W. S. Doan. Refrig. World, vol. 54, no. 4, Apr. 1919, pp. 32-34, 4 figs. Methods of purging permanent gases from condenser without losing a great amount of ammonia. (Concluding article.)

Refrigeration by Steam Compression (Entwicklungsformen des Dampf-Kälteprozesses), P. Ostertag. Schweizerische Bauzeitung, vol. 73, no. 4, Jan. 25, 1919, pp. 33-35, 8 figs. Schemes of plants operating on this principle, with reference to plant exhibited by Sulzer Bros. at Berne exposition in 1914.

Fruit, Cold Storage for

Cold Stores for Fruit in Denmark (Forsøgsanlæg paa Statens Havebrugs-Forsøgsstation ved Blangstedt), Erik Helten. Ingeniören, vol. 28, no. 14, Feb. 15, 1919, pp. 89-91, 4 figs. Installation of horizontal double-acting CO_2 machine.

Ice Plants

Deterioration of Ice Plants, Fred Ophuls. Ice & Refrigeration, vol. 56, no. 4, Apr. 1919, pp. 201-202. Advisability of making repairs of any defect as soon as same is discovered.

Competition and Coöperation among Ice Manufacturers, T. Robert Appel. Ice & Refrigeration, vol. 56, no. 4, Apr. 1919, pp. 202-205. Coöperation as a remedy for eliminating competition.

RESEARCH

Bureau of Mines, Pittsburgh Station

The New Pittsburgh Station of the Bureau of Mines, Pts. 1 and 2, George W. Harris. Coal Age, vol. 15, nos. 16 and 17, Apr. 17 and 24, 1919, pp. 707-711 and 749-751, 6 figs. Apr. 17: Consists of central administration building and two wings, one containing the chemical laboratories and the other the mechanical laboratory. Apr. 24: During war, station was devoted to assisting in war work. It is now being organized to operate on a peace basis. (To be continued.)

Government Bureau, Heating and Ventilation

Heating and Ventilation a National Issue, Werner Nygren. Domestic Eng., vol. 87, no. 2, Apr. 12, 1919, pp. 47-49 and 86. Advocates Government research bureau.

Laboratory Organization

The Functions of a Research Laboratory, Saul Dushman. Can. Chem. Jl., vol. 3, no. 4, Apr. 1919, pp. 118-121. Internal organizations and results of research laboratory of General Electric Co.

Laboratory Research and Mill Practice

Relations of Laboratory Research to Mill Practice. Metal Indus., vol. 17, no. 4, Apr. 1919, pp. 174-176, 7 figs. Value of metallurgical research and chemical analyses. Illustrated by examples in which the defects in structure were determined by these processes. From Scovill Bul.

The Relationship between the Laboratory and the Workshop, W. R. Barclay. Engineering, vol. 107, no. 2779, Apr. 4, 1919, pp. 456-457. In reference to principles of operation and objects of accomplishment both in laboratory and in workshop. Paper read before Inst. of Metals.

The Scope of the Works Laboratory, Frederick C. A. H. Lantsberry. Engineering, vol. 107, no. 2779, Apr. 4, 1919, pp. 437-438. Particular reference is made to service given by research laboratory in metallurgical and chemical works. Paper read before Inst. of Metals.

Municipal Testing Laboratory

The Organization of a Standard Municipal Testing Laboratory, J. O. Preston. Cornell Civil Engr., vol. 27, no. 2, Mar. 1919, pp. 50-65, 1 fig. Reasons for establishing it and fundamentals of design.

Organization

The Government and the Organisation of Scientific Research—I & II, Frank Heath. Chemical News, vol. 118, nos. 3074 & 3075, Mar. 14 and 21, 1919, pp. 127-129 and 134-137. Policy advocated by Advisory Council is encouraging research workers, organizing research by industries and establishing national research. Paper read before Roy. Soc. of Arts.

STANDARDS AND STANDARDIZATION

Chemical Standards

Chemical Standards in Relation to the Iron and Steel Trades, H. W. Brearley. Jl. Soc. Chem. Indus., vol. 38, no. 6, Mar. 31, 1919, pp. 97R-98R. Claims that advent of regular microscopic examination and what are called metallographic methods has caused a steady decline in the value of chemical analysis as a means of determining specifications for high-class steel material. Comments on Chem. Standards in issue of Feb. 15, p. 15T.

Industrial Standards

Engineering and Industrial Standardization, C. A. Adams. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 4, Apr. 1919, pp. 549-559. Machinery proposed by Am. Engrs. Standards Committee to create and regulate industrial standards.

Standardized-Parts Production

The Production of Standardized Parts—I, Herbert C. Armitage. Machinery, vol. 14, no. 341, Apr. 10, 1919, pp. 55-57, 2 figs. Jigs, tools and special machines; formulæ of output to pay for tools. Paper read before Instn. Mech. Engrs.

Turbo-Generators

Standardization of Turbo-Generators (Normalisation des groupes électrogènes à turbines à vapeur). Revue Générale de l'Electricité, vol. 5, nos. 14 and 15, Apr. 5 and 12, 1919, pp. 517-527 and 551-556, 4 figs. Specifications prepared by technical committee of the Chambre Syndicate des Constructeurs de Gros Matérial électrique. Apr. 5: concerning turbine and coupling. Apr. 12: relating to electrical part.

See also MECHANICAL ENGINEERING, Foundries (Standardization).

STEAM ENGINEERING

Boiler Heads

Areas of Segments of Boiler Heads, C. H. Berry. Power, vol. 49, no. 17, Apr. 29, 1919, pp. 644-645 4 figs. Charts based on formulæ quoted in paragraphs 214 and 217 of Am. Soc. Mech. Engrs. boiler code, edition of 1918.

Boiler, Hudson

The Hudson Patent Cylindrical and Water Tube Boiler. Colliery Guardian, vol. 117, nos. 30-40, Apr. 4, 1919, p. 777, 4 figs. Large water-holding capacity and steam reserve of Lancashire type, combined with quick steaming properties and positive circulation of water-tube type, has been aimed at in design.

Cross-Compound Engines

Checking Up Alignment, George H. Wallace. Power Plant Eng., vol. 23, no. 8, Apr. 15, 1919, pp. 367-368. Procedure in case of cross-compound engine.

Safety Valves

Some Important Points on Boiler Heating Surface, G. J. Wells. Mar. Eng. of Canada, vol. 9, no. 3, Mar. 1919, pp. 120-121 and 70. Report of committee giving regulations for determining size of safety valve of ordinary type required on each boiler. Paper read before Inst. Mar. Engrs.

Turbines

Some Aspects in Steam Turbine Design. Steamship, vol. 30, no. 358, Apr. 1919, pp. 229-232. Progress of steam turbine as commercial proposition, particularly as applied to marine propulsion. Paper read before Assn. Eng. & Shipbuilding Draftsmen.

See also MECHANICAL ENGINEERING, Heating and Ventilation (Steam Flow), Power Plants (Turbines, Turbo-Generators).

THERMODYNAMICS

Gasoline Vapor

Physical Properties of Gasoline Vapor (Propriétés physiques de la vapeur de pétrole), Jean Rey. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 10, Mar. 10, 1919, pp. 509-513. Deduced from the entropic diagram presented in Comptes rendus vol. 166, 1918, p. 387.

Heat Flow

The Transmission of Heat Through Heavy Building Materials, Eng. & Contracting, vol. 51, no. 18, Apr. 30, 1919, pp. 442-443. Experiments carried out by Dept. of Heating and Ventilating Eng. of University of London.

Mechanical Equivalent of Heat

Sadi Carnot's Determination of the Mechanical Equivalent of Heat (La détermination de l'équivalent mécanique de la chaleur par Sadi Carnot), L. Décombe. Revue Générale de l'Electricité, vol. 5, no. 12, Mar. 22, 1919, pp. 442, 443. Expressions used by Carnot in his Reflexions on the Motive Power of Fire are quoted to prove that he was the first to establish the two thermodynamic laws. Paper before l'Académie des Sciences, Feb. 3, 1919. (See Comptes rendus, vol. 168, pp. 268-271.)

How Carnot Calculated the Mechanical Equivalent of Heat. An unpublished Document (Comment Carnot a calculé l'équivalent mecanique de la chaleur. Un document inédit), C. Raveau. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 11, Mar. 17, 1919, pp. 549-552. Quotes from Notes Inédites de Sadi Carnot expression writer used in connection with experiments on work done in isothermal expansion of a given volume of gas.

Radiation

Note on the Coefficient of Total Radiation of a Uniformly Heated Enclosure, W. W. Coblentz. Jl. Wash. Acad. Sci., vol. 9, no. 7, Apr. 4, 1919, pp. 185-187. Experimental verification of writer's previous conclusion in regard to value of Stefan-Boltzmann constant of radiation.

Specific Heats of Aqueous Solutions

The Specific Heat of Aqueous Solutions, with Special Reference to Sodium and Potassium Chlorides, W. R. Bousefield and C. Elspeth Bousfield. Phil. Trans. Roy. Soc. London, Ser. A, vol. 218, no. 562, Feb. 25, 1919, pp. 119-156, 7 figs. Experimental study of contraction of water when a solute is dissolved in it with reference to specified heat of solution. A cylindrical Dewar vessel immersed in water bath as the calorimeter, and a "mercury resistance thermometer" as the electric heater.

WELDING

Acetylene Welding

Oxy-Acetylene Welding in the Railroad Shops, F. Hazeldine. Can. Machy., vol. 21, no. 14, Apr. 3, 1919, pp. 334-335. Facts regarding use of oxy-acetylene welding and cutting torch in railroad shop. Paper read before Instn. Mech. Engrs.

Oxy-Acetylene and the Safety First Movement, A. Cressy Morrison. Jl. Acetylene Welding, vol. 2, no. 11, May 1919, pp. 543-549. Safety in relation to manufacture and transportation of materials and apparatus used in connection with art of welding and cutting. Address delivered before Western Pa. Division of Nat. Safety Council.

The Oxy-Acetylene Torch in the Railway and Locomotive Engineering Field, J. F. Springer. Jl. Acetylene Welding, vol. 2, no. 11, May 1919, pp. 570-576. Principles of gas welding methods and survey of various applications in welding of sheet metal.

Oxy-Acetylene Welding, J. H. Davies. Acetylene & Welding Jl., vol. 16, no. 186, Mar. 1919, pp. 46-47. Experiments in welding of steels for the purpose of determining conditions for securing good results. Paper read before Instn. Mech. Engrs.

Oxy-Acetylene Welding An Important Factor in Poison Gas Manufacture. Jl. Acetylene Welding, vol. 2, no. 11, May 1919, pp. 556 and 558. Work of Chem. Warfare Service.

Welding by the Oxy-Acetylene Method—II, J. F. Springer. Automotive Eng., vol. 4, no. 4, Apr. 1919, pp. 181-183, 3 figs. Details of apparatus used and reasons for the use of each part. Suggestions in regard to adjusting flame. (To be continued.)

Aluminum

Improvements in the Autogenous Welding of Aluminum or Its Alloys. Acetylene & Welding Jl., vol. 16, no. 186, Mar. 1919, p. 60. Object of invention is to obtain a flux having melting point desired with use of no other salts than those of the halogen group.

Blowpipes

Improvements in Blowpipes. Acetylene & Welding Jl., vol. 16, no. 186, Mar. 1919, p. 59, 2 figs. Invention relates to welding blowpipe of the type having an attachment in the form of a tube adapted so as to be readily attached to the blowpipe.

Cast-Iron Welding

Hard Spots in Cast Iron Welding, S. W. Miller. Welding Engr., vol. 4, no. 4, Apr. 1919, pp. 19-24, 23 figs. Examination of various structures containing different percentages of carbon in the light of accepted metallurgical phenomena taking place in heat treatment, forms basis of suggesting cause of formation of hard spots and proposing remedy for avoiding same.

Electric Welding

Electric Arc Welding, F. A. Anderson. Mech. Eng., vol. 41, no. 5, May 1919, pp. 452-454, 8 figs. Its application to expanding pipe into flange, with reference to special instance in which weld was tested in various ways. Paper read before San Francisco Section Am. Soc. Mech. Engrs.

The Application of Electric Welding to Steel Shipbuilding, H. A. Hornor. Proc. Engrs. Soc. Western Pa., vol. 34, no. 10, Jan. 1919, pp. 641-670 and (discussion) pp. 671-676, 35 figs. Survey of extent of employment of electric welding in U. S. Set of standard symbols and nomenclature prepared by Electric Welding Branch, United States Shipping Board Emergency Fleet Corporation.

Electric Welding: Its Theory, Practice, Application and Economics, H. S. Marquand. Elecn., vol. 82, nos. 13 and 14, Mar. 28 and Apr. 4, 1919, pp. 350-352 and 377-379, 7 figs. Mar. 28: Properties of metals considered from welding point of view. Apr. 4: Thomson process of resistance welding; requirements of plants and application of method to chain welding, tire welding and wire welding; electro-percussive method. (To be continued).

Electric Welding and Welding Appliances—V, VI & VII. Engineer, vol. 127, nos. 3298, 3299 and 3300, Mar. 14, 21 & 28, 1919, pp. 241-243, 267-268 and 296-299, 18 figs. Quasi-arc coated-metal-electrode process.

Electric Arc Welding Principles, E. Wanamaker and H. R. Pennington. Ry. Elec. Engr., vol. 10, no. 4, Apr. 1919, pp. 107-110, 1 fig. Practice concerning metals used, their application and electrical characteristics. (Continuation of serial.)

Electric Welding and its Applications, Walter Leonard Lorkin. Jl. Roy. Soc. Arts, vol. 67, no. 3463, Apr. 4, 1919, pp. 304-314 and (discussion) pp. 315-317, 3 figs. Endeavors to show that process is simple, that it can be carried out with ordinary labor and that welds are efficient and effected at small cost.

Fusion in Arc Welding, O. H. Eschholz. Power, vol. 49, no. 12, Apr. 1, 1919, pp. 504-506, 19 figs. Effect of arc length, welding procedure, electrode material, arc current and electrode diameter upon such characteristics as penetration and overlap.

Notes on Electric Arc Welding. Eng. & Min. Jl., vol. 107, no. 17, Apr. 26, 1919, p. 743, 4 figs. Practice in construction of transformer tanks at Pittsfield works of General Electric Co.

Some Recent Applications of Arc Welding, Frank C. Perkins. Can. Machy., vol. 21, no. 12, Mar. 20, 1919, pp. 281-283, 8 figs. Explanation of process and of methods in use; illustrations of work done by aid of arc welding.

Suggestive Applications of Electric Arc Welding. Am. Blacksmith, vol. 18, no. 7, Apr 1919, p. 177, 9 figs. Welding of locomotive back flue sheet, flanged head and similar operations.

Electric Welding Machines

Winfield Electric Welding Machines. Car

Question What is the average life of a Heine boiler?

Answer: We don't know. The first Heine boiler ever built, after 35 years of constant use, is still serviceable, according to a certified statement by the Fidelity and Casualty Co.

Question Why is the Heine boiler capable of withstanding higher pressure than other boilers?

Answer: Made throughout of high grade tough steel of high tensile strength. Double staybolts are used for high pressures. Round—not elliptical—handholes.

Question Why is the Heine the most efficient boiler?

Answer: Large reverberatory combustion chamber. Hot gases are in constant touch with the heating surface from beginning to end of passes. No waste at turns. No dead gas pockets. Entire heating surface fully utilized. Always clean because of permanently installed soot cleaner.

Our war contribution was—nearly half a million horsepower of strong, durable, efficient Heine boilers.

Our peace contribution is—*more* strong, durable, efficient Heine boilers.

HEINE SAFETY BOILER CO.

5321 MARCUS AVENUE ST. LOUIS, MISSOURI

HELIOS

Machy., vol. 21, no. 15, Apr. 10, 1919, pp. 353-354, 3 figs. Motor-driven spot welder.

Emergency Repairs

Trials of an Army Welder in France. Jefferson A. Snyder. Jl. Acetylene Welding, vol. 2, no. 11, May 1919, pp. 566-570. Emergency repairs conducted under handicap of insufficient equipment.

Expansion and Contraction

Making Expansion Outwit Contraction. David Baxter. Jl. Acetylene Welding, vol. 2, no. 11, May 1919, pp. 558-566, 4 figs. Welding 400-lb. gasoline engine flywheel. Fractures consisted of two cracked spokes and a crack full length of the hub; cracks in spokes were near juncture of spokes and hub.

Gas Welding Apparatus

Some Welding Shop Ideas. David Baxter. Am. Blacksmith, vol. 18, no. 7, Apr. 1919, pp. 159-162, 5 figs. Construction details of compound heater gas burner and ladle and preheating torch.

Locomotive-Cylinder Welding

Welding a Locomotive Cylinder. Welding Engr., vol. 4, no. 4, Apr. 1919, pp. 34-40, 6 figs. Break was caused by cylinder bushing being loose in cylinder and turning around so that cylinder cock hole was plugged up, and piston coming forward pushed out whole front of cylinder including valve-chamber front.

Plastic Arc

The Plastic-Arc System of Welding. J. O. Smith. Motorship, vol. 4, no. 5, May 1919, pp. 36-37, 15 figs. Technical discussion of methods employed.

Preheating

Discussion of the Merits of Both Charcoal and Gas Preheating, Fred J. Maeurer. Welding Engr., vol. 4, no. 4, Apr. 1919, pp. 25-27, 8 figs. Recommends use of charcoal in preheating castings where expansion and contraction must be taken into consideration.

Steel, Mild

Welding Mild Steel, H. M. Hobart. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 4, Apr. 1919, pp. 561-609, 19 figs. Investigations undertaken by Welding Research Sub-Committee of Welding Committee of Emergency Fleet Corporation. General object was to extend use of welding in construction of merchant ships.

Thermite Welding

Repairing a Broken Crankshaft by Thermite, W. F. Sutherland. Can. Machy., vol. 21, no. 17, Apr. 24, 1919, pp. 404-405, 3 figs. Repair job on a 10-in. upsetting press crank done at Metal & Thermite plant, Toronto.

Welded Materials, Tests of

Tests of Welded Materials, Paul C. Tris, Maurice Kapetensky. Proc. Steel Treating Research Soc., vol. 2, no. 3, 1919, pp. 18-24 and 56, 16 figs. The metallurgical laboratory where welded parts of Liberty engine are tested is operated in three divisions, the chemical, the physical and metallographic laboratories. The experimental data secured in these divisions and the interpretation given to micrographs are set forth.

Welders, Training

Training a Welder. Jl. Acetylene Welding, vol. 2, no. 11, May 1919, pp. 550, 552 and 556, 1 fig. On training by apprenticeship. (To be continued.)

Welding and Cutting

Modern Welding and Cutting, pts. VII, VIII and IX. Ethan Viall. Am. Mach., vol. 50, nos. 14, 15 and 16, Apr. 3, 10 and 17, 1919, pp. 641-645, 675-679 and 733-737, 20 figs. Apr. 3: Thermit welding of cast iron and other parts. Apr. 10: History and uses of the gas torch. Apr. 17: Oxygen and hydrogen by the electrolytic method.

See also RAILROAD ENGINEERING, Shops (Welding); MARINE ENGINEERING, Yards (Welding).

WOOD

Seasoning

Practical Rules for the Seasoning of Wood, Harold S. Betts. Ry. Maintenance Engr., vol. 15, no. 5, May 1919, pp. 169-170, 2 figs. Suggestions in regard to uniform drying of timber with minimum exposure to decay.

Statistics of Production

Production of Lumber, Lath, and Shingles in 1917, Franklin H. Smith and Albert H. Pierson. U. S. Dept. of Agriculture, bul. no. 768, Apr. 5, 1919, 44 pp. Collection and compilation of statistics. Estimated total lumber production was 36,000,000,000 board feet.

See also RAILROAD ENGINEERING, Permanent Way and Buildings (Ties), Rolling Stock (Lumber for Freight Cars); MARINE ENGINEERING, Yards (Wooden Ships); CIVIL ENGINEERING, Harbors (Timber, Impregnated).

Organization and Management

ACCOUNTING

Brick Plant

Simplified System of Counting Cost, C. F. Mattes. Brick & Clay Rec., vol. 54, no. 7, Apr. 8, 1919, pp. 591-594. Suggested plan for average size brick plants.

Cost Accounting

Cost Accounting to Aid Production—VIII, G. Charter Harrison. Indus. Management, vol. 57, no. 5, May 1919, pp. 400-404, 1 fig. Diagram illustrating use of specification costs in ascertaining profits and losses made by individual salesmen.

Highway Contractors

Cost Keeping for Highway Contractors, H. P. Gillette. Contract Rec., vol. 33, no. 15, Apr. 9, 1919, pp. 336-338. Methods for determining unit costs, obtaining overhead costs and prorating them.

Inventories

How We Prepare for and Take Inventory, H. F. Harris. Factory, vol. 22, no. 4, Apr. 1919, pp. 681-686, 10 figs. Instructions given to men at plant of Republic Motor Truck Co.

EDUCATION

Employment Management

Government Course for Training Employment Managers, Meyer Jacobstein. U. S. Dept. Labor, Bur. Labor Statistics, Bul. 247, Jan. 1919, pp. 19-24. War-Emergency course.

Engineers

Specialization in Education of Engineers (Sulla specializzazione della educazione degl' ingegneri), Giuseppe Astorri. Ingegneria Italiana, vol. 3, no. 63, Mar. 13, 1919, pp. 169-171. High-school courses in Italy are found to be insufficiently adaptable to form a basis for subsequent engineering education.

Foundrymen

Industrial Education. Foundry Trade Jl., vol. 21, no. 206, Feb. 1919, pp. 98-102. Considered as means for developing industry, particularly in relation to the operation of a foundry. Address delivered before Scottish Branch British Foundrymen's Assn.

Mining

Mining and the Industrially Disabled, J. C. Murray. Can. Min. Inst. Bul. no. 84, Apr. 1919, pp. 393-398. Work being done by Canadian Government in rehabilitating war cripples.

Telephone Operation

The Cripple in the Telephone Field, Douglas C. McMurtrie. Telephony, vol. 76, no. 17, Apr. 26, 1919, pp. 31-32. Reëducation of injured or crippled employee estimated as more profitable to all concerned than disability compensation.

Vocational Training

Army Vocational Training, C. R. Dooley. Eng. Education, vol. 9, no. 7, Mar. 1919, pp. 263-277, 10 figs. Plan for organization adopted by Committee on Education and Special Training during emergency, which necessitated rapid training of 90,000 men for military service.

FACTORY MANAGEMENT

Clerical Work

Systematic Superintendence, Charles F. Dingman. Concrete, vol. 14, no. 3, Mar. 1919, pp. 84-87, 5 figs. Routine covering field clerical work on construction operations.

Cooperation, Internal

Necessary Internal Coöperation between Employer and Employee must be Mutually Evolved, Charles P. Steinmetz. Automotive Industries, vol. 40, no 16, Apr 17, 1919, pp. 831-833. Declares that capital and labor are equal necessities in modern industry and must be equally represented in management and distribution of profits.

Employment Management

Handbook of Employment Management in the Shipyard. United States Shipping Board Emergency Fleet Corporation, Employment Management Branch, Indus. Relations Division, bul. 3, 61 pp. Methods to be followed in process of selection and placement of new worker.

The Principles of Employing Labour. Eng. & Indus. Management, vol. 1, no. 9, Apr. 10, 1919, pp. 273-276. Factors determining selection of workpeople taking into account suitability of applicant for class of work he is expected to perform.

Employment Problem of the U. S. Naval Aircraft Factory, Frederic C. Coburn. Indus. Management, vol. 57, no. 5, May 1919, pp. 359-365, 9 figs. Organization of employment department.

The Organization of an Employment Department, Charles E. Fouhy. Eng. & Indus. Management, vol. 1, no. 8, Apr. 3, 1919, pp. 231-236, 16 figs. Routine of employment department of Curtiss Aeroplane & Motor Co.

Factory Layout

The Automobile Factory—I. Automobile Engr., vol. 9, no. 122, Jan. 1919, pp. 22-25, 9 figs. Layout, construction and equipment.

New South Philadelphia Plant of the Westinghouse Electric & Mfg. Co., H. T. Herr. Elec. Jl., vol. 16, no. 4, Apr. 1919, pp. 114-121, 22 figs. Layout indicating shop arrangement and safety features.

Garment Trade

Factory Management in Garment Trades, Mack Gordon. Indus. Management, vol. 57, no. 5, May 1919, pp. 345-349, 1 fig. Methods of controlling production, economizing materials and expediting manufacture. (To be continued.)

Industrial Conferences

The Joint Industrial Conference. Eng. & Indus. Management, vol. 1, no. 8, Apr. 3, 1919, pp. 242-243. Methods of negotiation between employers and trade unions. Report of Provisional Joint Committee appointed by Nat. Indus. Conference.

Machine-Tool Plant

Organization and Management of a Machine Tool Plant—II & III, Oskar Kylin and Erik Oberg. Machy., vol. 25, nos. 8 and 9, Apr. and May, 1919, pp. 698-702 and 813-820, 29 figs. On principles of organization and details of system used in a medium-size machine tool-manufacturing plant making a single line of machines.

The New Home of Pratt & Whitney Co., Ltd., J. H. Moore. Can. Machy., vol. 21, no. 14, Apr. 3, 1919, pp. 321-324, 8 figs. Description of plant design and arrangement to manufacture small tools on great scale.

Material Keeping

Keeping Track of Factory Material—H. J. G. Hickman. Factory, vol. 22, no. 4, Apr. 1919, pp. 702-707, 12 figs. Forms used in disbursing purchased and manufactured material.

Office Arrangement

The Largest Gas Utility Company in the World. Gas Age, vol. 43, no. 7, Apr. 1, 1919, pp. 335-338, 8 figs. Office arrangement of Consolidated Gas Co. of New York.

Organization in Industry

"Technicracy"—Ways and Means to Gain Industrial Democracy, William Henry Smyth. Indus. Management, vol. 57, no. 5, May 1919, pp. 385-389. Discusses ways and means to develop, guide and direct social organization in industry.

Industrial Coöperation, Charles P. Steinmetz. Eng. & Min. Jl., vol. 107, no. 17, Apr. 26, 1919, pp. 748-749. Systems for developing coöperation between capital and labor. Speech delivered at special session of Editorial Conference.

The Part of Capital and Management in Industry. Stone & Webster Jl., vol. 24, no. 4 Apr. 1919, pp. 289-292. Argues that coöperation is none the less real or mutually helpful because the division of profits is unequal.

Problems of Industrial Organization, Major Greenwood. Quarry, vol 24, no. 266, Apr 1919, pp. 106-108. Also Machy. Market, no 961, Apr. 4, 1919, pp. 21-22. Researches on conditions, excluding those determining efficiency of inanimate machines, which help or hinder industrial output, conducted under auspices of Health of Munition Workers Committee and the Welfare and Health Section of the Ministry of Munitions. Paper read before Roy. Statistical Soc.

Pacific Coast

Possibilities of Intensive Manufacturing on the Pacific Coast, G. N Somerville. Pac. Ma Rev., vol. 16, no. 4, Apr. 1919, pp. 110-112,

Let Us Do Your Special Work

Production Work and Special Work *started right* will be *finished right*

Work to be finished right must be started right—must be designed right—and that is where the S. A. S. designing and drafting departments come in. These departments are made up of specialists who can solve your problems—to develop and perfect your special device or duplicate accurately your unusual special part. Here is where your work starts and starts right.

Designing and Engineering Department

A department of high-salaried experts—thoroughly skilled and experienced, who can and will give authoritative supervision to designing, development and production—in this department all speculative elements are eliminated, and accuracy and perfection assured in the finished product.

Drafting Department

A department of specialists—well versed in layout, design, detail and materials — each draftsman thoroughly familiar with every detail of the particular work in which he specializes from practical experience as well as through years of study.

Get the benefit of this expert service

Where we fit in to help you:

—when your proposition is nothing but an idea, or planned out, so to speak, on paper
—when doubt arises whether to continue production of a special part or device
—when you meet continuous trouble in production
—when necessary special work becomes profitless and too expensive for you to produce
—when you lack room or special equipment for production

This is the third of a series of advertisements showing our plant, our methods and the work we do—Our model room in the next issue.

Our staff of experts and our developing and production laboratories are especially organized to assist you.

Write to-day and learn just how we can serve you.

LET US BUILD YOUR SPECIAL MACHINES

Production Control

Keeping Tra... ... Production. Henry A. Noar. Am. Mac... ...l 50, no. 16, Apr 17, 1919, pp. 745-747, 5 figs. Device designed ... provide uniform met...ods throughout plant.

Production Systems

Turning Out ... Tractors per Day—II. P. M. Heldt. Automotive Industries, vol. 40, no. 16, Apr. 17, 1919, pp. 852-857, 10 figs Production system employed at Milwaukee plant of Internat. Harvester Co.; details of machining and ...ssembling methods.

Railroad Tracks

The U. ... & S. Co.'s Operating Methods. Coal Trade J., ... 50, no 16, Apr 16, 1919, pp. 407-409, 5 figs. Arrangement of railroad tracks said to have effected important economies.

Shop Management

Lay-out and P...-Rate Card System. Machinery, vol. 13, no. 338, Mar. 20, 1919, pp. 692-694, 13 figs. Forms for use in shop management.

Scientific Factory Management—II & III. A. D. Denning. Eng. & Indus. Management, vol. 1, nos. 8 & 9, Apr. 3 & 10, 1919, pp. 246-249 and pp. 278-282. Functions of foremen; functions of workers. Third and concluding lecture of series delivered under auspices of Birmingham Section of Inst. of Metals.

Advances in Industrial Management. John Calder. Am. Mach., vol. 50, no. 17, Apr. 24, 1919, pp. 807-809. Address before Indus. Conference of N. Y. Business Publishers Assn.

Shop-Order Origination

Managing for Maximum Production—III. L. V. Estes. Indus. Management, vol. 57, no. 5, May 1919, pp. 379-384, 11 figs. Takes up origination of shop order and shows its connection with the various operations and control of manufacturing.

Standardized Parts

Production of Standardized Parts. Herbert C. Armitage. Eng. & Indus. Management, vol. 1, no 9, Apr. 10, 1919, pp. 266-272, 8 figs. Development of engineering methods in manufacture of jigs, tools and special machines (To be continued.)

Task Setting

The Human Factor in Task Setting. Eng. & Indus. Management, vol. 1, no. 9, Apr. 10, 1919 pp. 263-265, 1 fig. Suggests that task be not made so small as to prevent cost reduction, nor so large that worker can exceed it by a wide margin and so have it lose its significance

Tool Rooms

The Tool Room. E. Hayes Page's Eng. Weekly, vol 34, no 759, Mar 29, 1919, pp. 185-187, 4 figs Interchangeability of tools as factor in economic production of machinery.

LABOR

Employee Representation

How ... Democracy Works at Our Plant. Factory, vol 22, no. 4, Apr. 1919, pp. 677-681, 2 figs. Evolution from national government form of management to present day structure of employee representation in plant of Printz Biederman Co.

Housing

The Town of K... ...wa. Thomas Adams. Can Engr., vol ... ... Feb. 27, 1919, pp 260-262, 3 figs. Housing ... for employees of Riordon Pulp & Paper Co.

Miners' Cottages in Kent. Iron & Coal Trades Rev., vol. 98, no 2664 Mar. 21, 1919, p. 354, 2 figs. Particulars and dimensions of accommodation provided.

Good Housing and Labor Turnover. Leslie H. Allen. Am. Contractor, vol. 40 no. 15, Apr. 12, 1919, p. 23. Labor turnover is attributed to poor housing, because, it is stated, good housing has not kept up with healthful factory surroundings.

Labor Policies

Labor Program of the Department of Labor. William B. Wilson. U. S. Dept. Labor, Bur. Labor Statistics, Bul. 247, pp. 160-171. Based, it is said, on experience acquired during war.

Outline of a National Labor Policy. Ordway Tead. U. S. Dept. Labor, Bur. Labor Statistics, Bul. 247, pp. 148-155. Criticises statements advanced by employers in regard to policy followed by Government during war.

The Principles of Industrial Relations. Eng. & Min. Jl., vol. 107, no. 17, Apr. 26, 1919, pp. 754-756. Statement prepared by special committee of Chamber of Commerce of U. S. A., with a view of furnishing a basis on which American industry can build a national labor program

Labor Situation

The Present Labor Situation. Morris L. Cooke. U. S. Dept. Labor, Bur. Labor Statistics, Bul. 247, Jan. 1919, pp. 63-65. Suggestions in regard to activities which writer believes may be assumed by Dept. of Labor in addition to its present work.

Nova Scotia Collieries

Industrial Relations at the Collieries in Nova Scotia. F. W. Gray. Can. Min. Inst. Bul., no. 84, Apr. 1919, pp. 389-393. Attitude of workers towards proposed affiliation with United Mine Workers of America.

Repeaters

Is it Wise to Hire the Repeater? Leonard Blakey. Indus. Management, vol. 57, no. 5, May 1919, pp. 390-399, 10 figs. Study of turnover with reference to causes for leaving and duration of service on reëngagement.

Salaries

Classification of Salaries. J. L. Jacobs. Can. Engr., vol. 36, no. 13, Mar. 27, 1919, pp. 341-342. Principles and procedure in standardization of engineering salaries, particularly in regard to railroad positions. Address before Chicago R. R. Conference.

Soldiers and Sailors

Statement of Policy Relative to Employment of Returning Maryland Soldiers and Sailors. Baltimore, vol. 12, no. 7, Apr. 1919, pp. 15-16. Adopted by Employment Managers' Circle of Merchant & Mfrs. Assn. and other prepresentatives of industry.

Wage Rates

Cost of Living Studies as a Basis for Making Wage Rates. Royal Meeker. U. S. Dept. Labor, Bur. Labor Statistics, Bul. 247, Jan. 1919, pp. 43-50. Advocates this system in order to reduce dissatisfaction and bases estimates made on what is termed an adjustable basis.

The Different Systems of Wages (Les différents systèmes de salaires). Métallurgie, vol. 51, no. 13, Mar. 26, 1919, pp. 714-715, 2 figs. Taylor and Gantt systems. (Continuation of serial.)

Analyzing Bonus and Piece Work Systems—I. W. F. Rockwell. Am. Drop Forger, vol. 5, no. 4, Apr. 1919, pp. 162-166. Halsey, Rowan and Taylor plans.

Welfare Work

Developing Pride and Interest in the Job. W. R. Basset. Factory, vol. 22, no. 4, Apr. 1919, pp. 693-696, 4 figs. Suggests hiring welfare worker or personnel manager. Third article.

Modern Industrial Plants—VIa. George C. Nimmons. Architectural Rec., vol. 45, no. 4, Apr. 1919, pp. 343-355, 12 figs. Influence of employees' welfare work in reducing labor turnover.

Women

Women in Industry. H. E. Miles. U. S. Dept. Labor, Bur. Labor Statistics, Bul 247, Jan 1919, pp 119-129. Opinions of executives concerning efficiency of women and records obtained in countries where they have been engaged in industry.

Standards for Women Employees. Hugh Fullerton. U. S. Dept. Labor, Bur. Labor Statistics, Bul. 247, Jan. 1919, pp. 106-111. Advocates throwing around women in industry an unusual precaution by reason of greater social evils which result from their weakening.

Women in the Lead Industries. Alice Hamilton. U. S. Dept. of Labor, Bur. of Labor Statistics, no. 253, Feb 1919, 38 pp. Lead industries in U. S.; British records of lead poisoning of women in white lead industry; degree of susceptibility of women and men to poisoning; prevention of poisoning.

LIGHTING

Carbide Lamps

Illumination and the Safety Problem. Charles C. Phelps. Coal Indus., vol. 2, no. 4, Apr. 1919, pp. 153-156. Advocates use of carbide lamp as brightest and safest form of illumination.

Good Factory Lighting vs. Increased Production. H. Leveridge. Elec News, vol. 28, no. 7, Apr. 1, 1919, pp. 41-43. Discussion of provisions adopted in recent code of lighting for factories, mills and other work places, prepared by a Commission of Assn. Elec. Contractors and Dealers.

See also ELECTRICAL ENGINEERING, *Lighting and Lamp Manufacture;* MECHANICAL ENGINEERING, *Gas Engineering (Lightings, (Mantles).*

PUBLIC REGULATION

Municipal Ownership

Municipal Ownership Evils. Walton Clark. Gas Record, vol. 15, no. 8, Apr. 23, 1919, pp. 245-250. Holds that municipal ownership of gas plants is contrary to proper theories of democratic government. Paper read before Pa. Gas Assn.

RECONSTRUCTION

Construction Programs

A Post-War Construction Program—II, Charles C. May. Architectural Rec., vol. 45, no. 4, Apr. 1919, pp. 325-342, 16 figs. Organization and activities of Building Bur. of Int. Committee of Y. M. C. A.

Labor Relations

A Factor of Industrial Reconstruction. M. Webster Jenkinson. Machy. Market, nos. 961 & 962, Apr. 4 & 11, 1919, pp. 23-24 and 21. Recommends removing fear of workers that cost statistics will mean pressure put on them to work harder.

Machine Tools

Machine Tools. Alfred Herbert. Machy. Market, nos. 961 & 962, Apr. 4 & 11, 1919, pp. 19-20 and 17-18. Importation into England of American tools developed under conditions of expensive labor, has, in the writer's opinion, been of service in preparing that country to meet similar conditions. Paper read before North-East Coast Instn. Engrs. & Shipbuilders.

Telephone Booths

Market for Telephone Goods in Asia. Telephone Engr., vol. 21, no. 4, Apr. 1919, pp. 137-141, 3 figs. Extracts from Special Agent's series no. 172, Department of Commerce.

SAFETY ENGINEERING

Blasting, Quarry

Quarry Blasting with Electricity. A. S. Anderson. Cement & Eng. News, vol. 31, no. 4, Apr. 1919, pp. 32-34, 3 figs. Precautions to be observed.

Dust Inflammability

Inflammability of Carbonaceous Dusts in Air and in Atmospheres of Low Oxygen Content. H. H. Brown. Jl. Franklin Inst., vol. 187, no. 4, Apr. 1919, pp. 504-506, 1 fig. Research of Grain Dust Explosion Investigation Laboratory, Bur. of Chemistry.

Fire Prevention

Final Report of the Fire Prevention Section of the United States War Industries Board. Laboratories' Data, Underwriters' Laboratories, Nat. Board of Fire Underwriters, no. 1, Feb. 1919, pp. 11-16. Conditions existing in respect to fire hazard in privately owned property where machinery, material or supplies used for war purposes were manufactured, handled or stored.

See also Sprinklers and Dust Inflammability.

Gas Masks

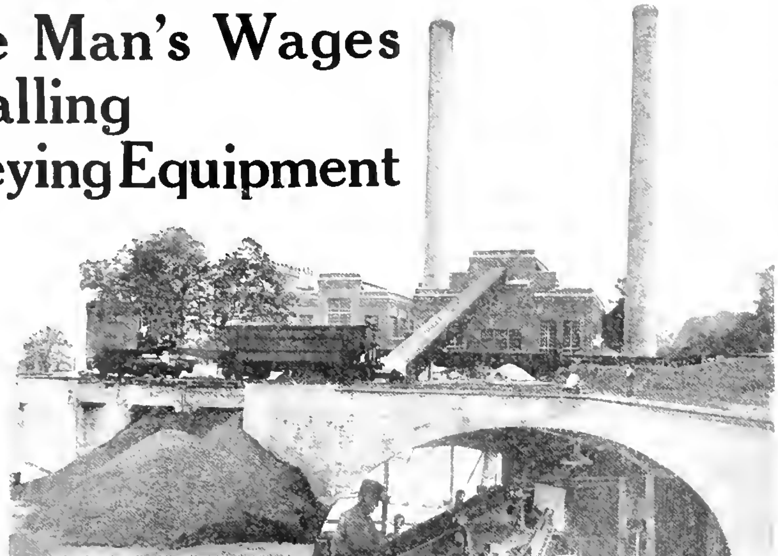
Army Gas Masks in Sulphur-Dioxide Atmospheres. A. C. Fieldner and S. H. Katz. Eng. & Min. Jl., vol. 107, no. 16, Apr. 19, 1919, pp. 693-695, 3 figs. Sectional diagrams of type adopted for use in smelters and sulphide roasters.

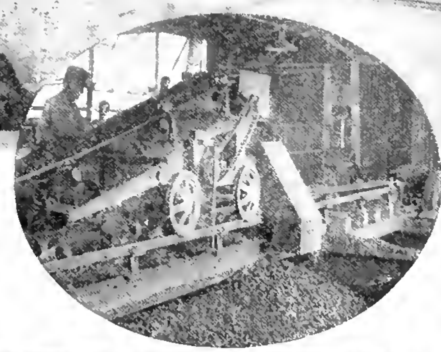
Respirators, Gas Masks and Oxygen Apparatus. Commercial America, vol. 15, no. 10, Apr. 1919, pp. 39-41. Work of Bureau of Mines in providing industrial workers with means of protection against gases incident to mining, fire, accident and various manufacturing processes.

Human Factor

The Human Factor in Accident Occurence. Eng. & Indus. Management, vol. 1, no. 9, Apr. 10, 1919, pp. 261-262. Inexperience and overwork in their relation to accident rates.

Handling Costs Reduced from $65 Daily to One Man's Wages by Installing Jeffrey Coal Conveying Equipment



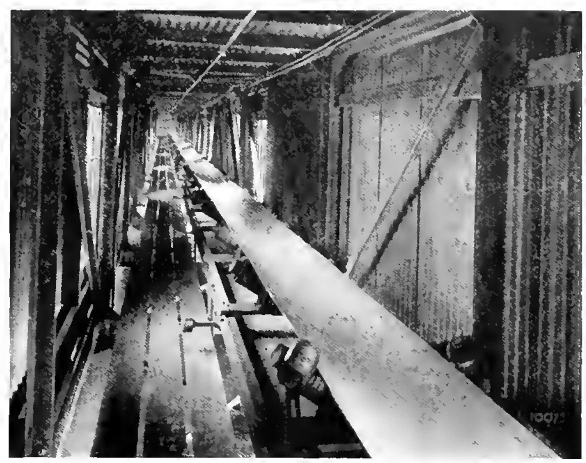


Showing interior view of head end of 20-in. Belt Conveyer over bunkers operated over a self-propelling belt tripper.

The new generating plant of the Mansfield Electric Light and Power Company, located at Melco, Ohio, 13 miles southeast of Mansfield, offers a striking example of the economies that can be effected by the substitution of modern equipment for old time methods. All equipment used is the last word in efficiency.

The coal for this plant is unloaded from railroad cars into a steel hopper, or dumped into a submerged storage into a 2000-ton concrete bin, which now stands where the coal pile is shown in top illustration.

From track hopper, a 30-in. Reciprocating Plate Feeder regulates the flow of coal to a Jeffrey 30 in. x 30 in. Single Roll Crusher, as shown in lower illustration, and a Jeffrey 20-in. Belt Conveyor carries the crushed coal to boiler house and distributes to bunkers.



20-in. Belt Conveyer in the inclined portion from Crusher to boiler house

The Conveyor proper consists of 736 ft. of 20-in., five-ply rubber belting. It is driven at a speed of 258 feet per minute and is supported by 80 standard 20-in., three-pulley troughing idlers, 36-20-in. return idlers and sufficient guide idlers.

The Jeffrey Equipment has a rated capacity of 50 tons of coal per hour, although the engineers in charge of this installation state that it is many times called upon to handle up to 70 tons per hour.

Write for Jeffrey Catalog No. 175-W, featuring this and numerous other Belt Conveyer Installations.

The Jeffrey Mfg. Co.

904 North Fourth Street
Columbus, Ohio

Handle it Mechanically

Showing Reciprocating Plate Feeder under Track Hopper and 30 in. x 30 in. Single Roll Crusher which discharges the coal on foot end of belt conveyer.

Respirators

See Gas Masks, page 20*a*.

Sprinklers

New Code for Automatic Sprinklers. Am. Architect, vol. 115, no. 2261, Apr. 23, 1919, pp. 588-595, 4 figs. Rules for fire extinguishing appliances (sprinkler system), adopted May 24, 1917, by Board of Standards and Appeals, as amended May 2, 1918, and Jan. 2, 1919, effective from Feb. 17, 1919.

Welding

Safety Rules for Oxy-Acetylene Welding. Machy. (N. Y.), vol. 25, no. 8, Apr. 1919, pp. 733-735, 3 figs. Adopted by Western Pennsylvania Division of Nat. Safety Council.

See also MINING ENGINEERING, Coal and Coke, Mines and Mining (Accidents), (Safety Lamps); CIVIL ENGINEERING, Building and Construction (Sprinklers).

SALVAGE

Sacks, Cement

The Proper Handling of Empty Cement Sacks. E. V. Aldridge. Ry. Maintenance Engr., vol. 15, no. 4, Apr. 1919, pp. 123-125, 1 fig. Practices of user and manufacturer which affect the salvage of cement sacks.

TRANSPORTATION

Truck Transportation

Ship-by-Truck Movement Invades South to Prove Great Benefits of Highway Transport. Commercial Vehicle, vol. 20, no. 6, Apr. 15, 1919, pp. 19-21 and 29, 6 figs. Georgia demonstration in which 37 trucks delivered 100 tons of goods to cities within 50-miles radius.

Economical Organization of Transport Trucks in a Large City (L'organisation économique des transports industriels automobiles dans une grande ville). Emile Belot. Journal des Usines à Gaz, vol. 43, no. 6, Mar. 20, 1919, pp. 93-95. Analytical determination of number of workmen, employed for loading and unloading, which will reduce transportation price per ton to a minimum. From Comptes rendus des séances de l'Académie des Sciences, no. 8, Feb. 24, 1919.

Tunnel, Vehicular, New York-New Jersey

The New York and New Jersey Vehicular Tunnel, Edward A. Byrne. Eng. World, vol. 14, no. 8, Apr. 15, 1919, pp. 33-37, 6 figs. Reasons for constructing it and plans of various proposed projects. Paper presented before N. Y. Branch Am. Soc. Civil Engrs.

Water Transportation

The Development of American River Traffic —I. Shipbuilding & Shipping Rec., vol. 13, no. 14, Apr. 3, 1919, pp. 406-408, 3 figs. Plans for towing steamers and steam barges on Mississippi and Black Warrior Rivers.

See also MINING ENGINEERING, Coal and Coke (Transportation); MUNITIONS AND MILITARY ENGINEERING (Railroad Transportation); AERONAUTICS, Aircraft (Transport Service).

Electrical Engineering

ELECTROCHEMISTRY

Electromotive Force of Metals

Electromotive Force of Metals (Force électromotrice des métaux). J. A. Montpellier. Industrie Electrique, vol. 28, no. 642, Mar. 25, 1919, pp. 103-104. Ionic phenomena in thermocouples and table of relative potentials of metallic elements.

Importance

Electrochemistry in its Human Relations. F. J. Tone. Chem. & Metallurgical Eng., vol. 20, no. 8, Apr. 15, 1919, pp. 413-415. Electrochemistry can contribute to human progress and raise standard of living by providing cheap fertilizer for increased crop yields, improve sanitation and produce new materials of construction.

Nelson Cell

The Nelson Electrolytic Chlorin Cell. C. F. Carrier, Jr. General Meeting Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 16, pp. 221-231, 3 figs. History, development, construction and operation of the Nelson cell, including particularly the life of its different parts, ampere efficiency and energy efficiency with which it works.

Sodium Permanganate

An Electrolytic Process for the Production of Sodium Permanganate from Ferromanganese, Robert E. Wilson and W. Grenville Horsch. General Meeting Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 15, pp. 207-220, 1 fig. Ferromanganese anodes were used in diaphragm cell in sodium carbonate solution, with production of an 8 to 12 per cent solution of sodium permanganate in anode compartment.

ELECTRODEPOSITION

Copper Plating on Iron

Electro-Plating on Iron from Copper Sulphate Solution, Oliver P. Watts. Brass World, vol. 15, no. 4, Apr. 1919, pp. 108-111. Shows that certain solutions of lead and antimony may be substituted for the arsenic dip, previous to direct-current plating of copper on iron from copper sulphate. Paper read before Am. Electrochem. Soc.

Plating Room Chemicals

Plating Room Chemicals. A. Schleimer. Brass World, vol. 15, no. 4, Apr. 1919, pp. 127-129. Appearance and properties of borax, charcoal, cobalt, copper acetate, copper sulphate, copper carbonate, corrosive sublimate, liver of sulphur, nickel salts, magnesium sulphate, lead acetate, caustic potash, sodium carbonate and cyanide.

ELECTROPHYSICS

Conservation of Electricity

Conservation of Electricity and the Electronic Theory (La conservation de l'électricité et la théorie électronique). L. Décombe. Revue Générale de l'Electricité, vol. 5, no. 12, Mar. 22, 1919, pp. 443-444. Admitting the electric constitution of matter, various experimental researches are presented in support of theory establishing conservation of electrical moment in a dielectric by assimilation of atoms to doublets of variable moment. Paper before la Société française de Physique.

Dielectric Phenomena

Dielectric Phenomena in Dielectric Substances (in Japanese). K. Kamibayashi. Denki Gakkwai Zasshi, no. 368, Mar. 10, 1919.

Electronic Emission

The Emission of Electricity from Incandescent Bodies (L'émission de l'électricité par les corps incandescents). A. Boutaric. Revue Générale des Sciences, vol. 30, no. 6, Mar. 30, 1919, pp. 171-183, 6 figs. Survey of experimental research by various investigators, notably O. W. Richardson. Theories offered in explanation of electronic emission. First article.

FURNACES

Crucibles

Morgan's Patent Electrically Heated Crucibles. Electrical Review, vol. 84, no. 2157, Mar. 28, 1919, pp. 342-344, 4 figs. Designed to prevent volatilization of non-ferrous alloys which takes place when arc is used on account of excessive heat.

Rennerfelt

Types of Electric Furnaces—I: the Rennerfelt, W. F. Sutherland. Can. Machy., vol. 21, no. 14, Apr. 3, 1919, pp. 328-330, 7 figs. Operating characteristics; tilting mechanism and control and wiring diagram of furnace.

Developments in the Rennerfelt Furnace. H. A. de Fries and Jonas Hertenius. Eng. & Indus. Management, vol. 1, no. 8, Apr. 3, 1919, pp. 238-239, 1 fig. Side electrodes tilt and shape of shell is round in new design.

Resistance Type

Electric Furnaces of the Resistance Type Used in the Production of Essential War Materials, T. F. Baily. General Meeting, Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 19, pp. 257-260, 1 fig. Heat-treating equipment intended for automatical and continuous hardening and tempering of cast-steel anchor chains. Heating is by an electrical resistor of granular carbon confined in carborundum firesand walls, machinery being controlled by pyrometers which allow of hardening and tempering at definite temperatures.

Steel Foundry

The Electric Foundry: Its Introduction into Foundry Practice. W. E. Moore. General Meeting Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 12, pp. 181-186. Comparison of electric furnace in steel foundry work with open-hearth furnace and small bessemer converter. Writer concludes that it is superior to both, in regard to cheapness of raw material, conservation of alloying metals, waste of lining, temperature obtainable, control of chemical composition and quality of steel produced.

Vom Baur

The Vom Baur Electric Steel Furnace. Iron Age, vol. 103, no. 17, Apr. 24, 1919, pp. 1071-1073, 2 figs. Electrode holders are so constructed that by means of fillers either graphite or carbon electrodes can be used. Tilting mechanism allows furnace to tilt backward 7 deg. so that slag can be taken off at this door instead of from the spout.

GENERATING STATIONS

Automatic Generating Plants

Automatic Induction Generator Plants. E. A. Quinn. Jl. Electricity, vol. 42, no. 8, Apr. 15, 1919, pp. 342-344, 7 figs. Description of two small power plants which make use of water normally used in larger plants of a light and power corporation under heads which existed in the flow line but had hitherto not been utilized. Plants are said to be operated without attendants.

Bus and Switches

Modern Bus and Switch Structures, C. D. Gray and M. M. Samuels. Elec. World, vol. 73, nos. 16 & 17, Apr. 19 & 26, 1919, pp. 788-792 and 831-833, 16 figs. Masonry, material, compartment doors and general arrangement. Types of circuit breakers and support of buses used with large generating units.

Canada

Central Electric Power Station Statistics. Can. Engr., vol. 36, no. 6, Feb. 6, 1919, pp. 203-205. Data gathered by Dominion Water Power Branch and Bureau of Statistics.

Electric Generation in Canada. Can. Engr., vol. 36, no. 9, Feb. 27, 1919, pp. 255-256. Table of central electric generating plants in Canada, showing capacity, ownership and prime movers.

The Present Electric Outlook in Canada, A. S. L. Barnes. Electrical Review, vol. 84, no. 2158, Apr. 4, 1919, pp. 389-390. Figures indicating total amount of power capable of developing and amount of power already developed. (Continuation of serial.)

Condenser, Static

Economic Use of Static Condenser—I & II, Waldo V. Lyon. Elec. World, vol. 73, nos. 15 & 16, Apr. 12 & 19, 1919, pp. 724-726 and 776-778, 6 figs. Increasing capacity of a generating plant by using static condensers to correct power factor; feasibility of putting less generating equipment in new plant by using condensers. Problems of power-factor correction by static condensers are analyzed for purposes of improving voltage regulation and reducing copper losses.

Prohibition

Effect of Prohibition on Lighting Revenue, Elec. World, vol. 73, no 15, Apr. 12, pp. 736-739. Conditions following prohibition as reported by 75 central stations.

Smethwick

Electricity Supply at Smethwick. Electrical Review, vol. 84, no. 2158, Apr. 4, 1919, pp. 368-371, 5 figs. Capacity of plant which was 12,475 kw. before the war has been increased to total of 36,325 kw. by installation of B. T. H. turbo-generators.

So. Philadelphia Works

Power System of South Philadelphia Works, Graham Bright. Elec. Jl., vol. 16, no. 4, Apr. 1919, pp. 126-131, 15 figs. Showing lighting arresters, disconnecting switches, etc.

Theft of Current

Detection and Remedy of Current Theft from Central Stations. Thomas Robson Hay. Elec. Rev., vol. 74, no. 15, Apr. 12, 1919, pp. 588-589. Methods employed by Duquesne Light Co. of Pittsburgh.

GENERATORS AND MOTORS

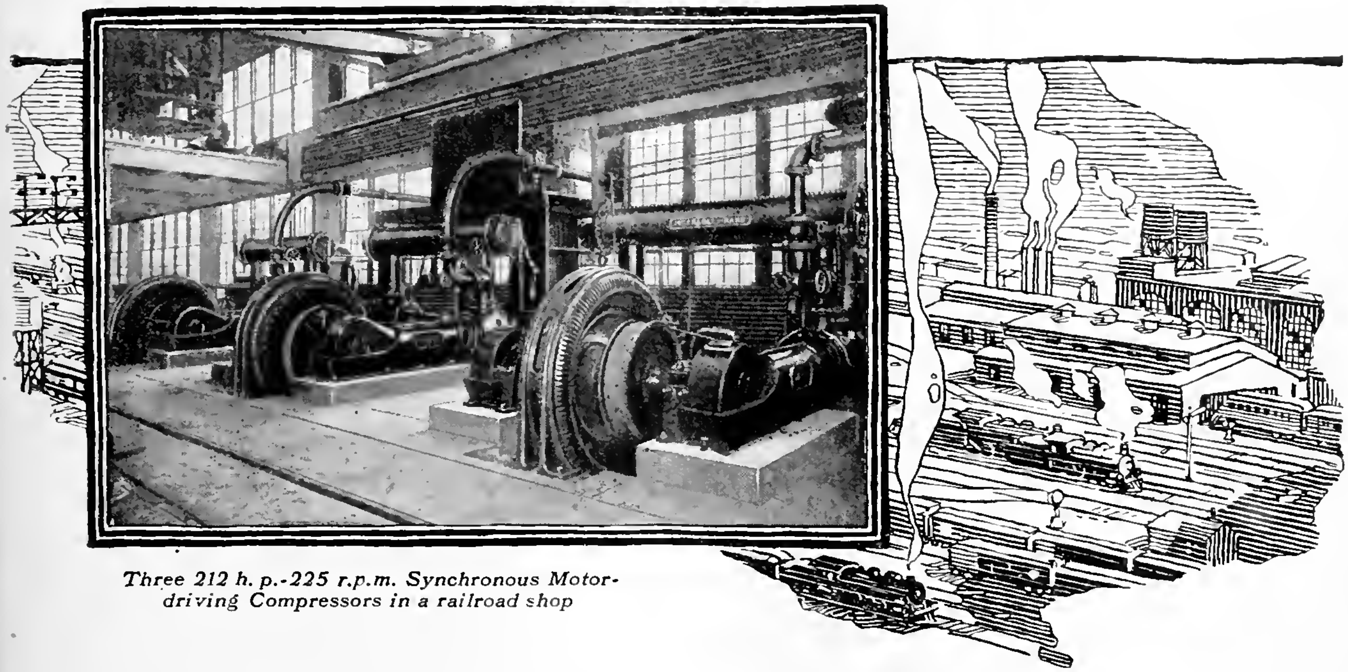
Alternators

Free Oscillations of Alternators in a Constant-Voltage System (Oscillations libres des alternateurs sur réseau a tension constante). André Blondel. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 9, Mar. 3, 1919, pp. 439-444. Values of K and e which make Δ a minimum, determined by taking advantage of the fact that changes in rI during oscillations are negligible by comparison to vector $(u - rI)$ when I is constant.

Asynchronous Machines

Theory of Elliptic-Field Asynchronous Machines (Sur la théorie des machines asynchrones à champ elliptique). W. Genkin. Revue Générale de l'Electricité, vol. 5, no. 15, Apr. 12, 1919, pp. 539-548, 15 figs. General equations derived from Fynn's theory. Equivalent circuit worked out for revolving-field motor, single-phase motor, phase converter and induction meter.

The high efficiency and dependability of G-E Synchronous Motors are relied upon in many industries today.



Three 212 h. p.-225 r.p.m. Synchronous Motor-driving Compressors in a railroad shop

88,000 h.p. of synchronous motors supplied in 1918 for air compressor drive

FOR a quarter century the General Electric Company has supplied synchronous motors designed for the particular work to be done. The first ones furnished are still in continuous service requiring maximum dependability.

For industrial drives these motors are furnished from 25 to 2000 h. p. capacity with speeds from 80 to 1800 r. p. m. and are designed to start any load met with in commercial practice without excessive current demands upon the power circuit.

The very high efficiency and dependability of these motors are due to their excellent design which is based on thorough testing of both raw materials and finished motors.

Our engineers will be pleased to supply additional information on these motors.

43-163

General Electric Company

General Office Schenectady, N.Y.

Application of the Diagram of Asynchronous Motors (Applications du diagramme des moteurs asynchrones), L. Lagron. Revue Générale de l'Electricité, vol. 5, no. 14, Apr. 5, 1919, pp. 507-510, 4 figs. How to use writer's diagram published in R. G. E., vol. 4, Dec. 7, 1918, p. 861, to modifying connection of coils, constructing characteristic curves and the starting of motor.

Heating

Maximum Power of Electrical Machines Limited by Permissible Heating of Parts (Etude analytique des conditions dans lesquelles, pour un échauffement determiné, la puissance de certaines catégories de machines électriques est maximum), H. Lajus. Revue Générale de l'Electricité, vol. 5, no. 13, Mar. 29, 1919, pp. 467-471, 1 fig. A d. c. generator or an alternator operating in constant cos ϕ theoretically assumed to be heated to the permissible limit can develop maximum power, according to the writer's investigations, when frequency is maximum and the sum of hysteresis and Foucault losses equals the Joule losses.

High-Frequency Generators

A High-Frequency Generator for Airplane Wireless Telegraph Sets, A. Nyman. Elec. Jl., vol. 16, no. 4, Apr. 1919, pp. 140-145, 16 figs. Scheme developed by Signal Corps for U. S. Army; requirements were lightness, compactness and reliability.

Lubrication

Lubrication of Electric Generators and Motors, Reginald Trautschold. Elec. Rev., vol. 74, no. 16, March 19, 1919, pp. 629-630. Influence of type of apparatus upon choice of lubricant.

Railway Motors

Manufacturers' Tests of Railway Motors, J. S. Dean. Elec. Ry. Jl., vol. 53, no. 16, Apr. 19, 1919, pp. 777-778, 9 figs. Chart presenting various detail parts with materials used in their manufacture. (First article of series.)

Rheostats

Starting Rheostats for Shunt Motors, Terrell Croft. Power House, vol. 13, no. 4, Apr. 5, 1919, pp. 90-91, 4 figs. Calculation of size of resistance to be placed in series with armature to prevent excessive current.

Single-Phase Generators

Armature Reaction and Wave Form of the Single Phase Generator (in Japanese), G. Shimizu. Denki Gakkwai Zasshi, no. 368, Mar. 10, 1919.

Switch-Gear, Starting and Controlling

Starting and Controlling Switchgear for Shipyard Machinery, A. P. Pyne. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 413-420, 21 figs. Review of working conditions of various motors to be encountered in a shipyard and suggestions in regard to selecting starting and controlling apparatus.

Synchronous Motors

Synchronous Motor Characteristics—I, Theo. Schou. Elec. World, vol. 73, no. 17, Apr. 26, 1919, pp. 828-830, 6 figs. Heyland diagram for induction motor is applied to synchronous motors with squirrel-cage windings in order to investigate starting and pull-in torques. Comparison of brass and copper for rotor bars.

IGNITION APPARATUS

Contact Breakers, Splitdorf

The New Splitdorf Magneto. Aerial Age, vol. 9, no. 6, Apr. 21, 1919, p. 304, 2 figs. Details of contact breaker.

Generators, Motor-Car

Regulation of Automotive Generators, W. A. Dick. Elec. Jl., vol. 16, no. 4, Apr. 1919, pp. 148-151, 11 figs. Regulation characteristics of generators used for lighting and other purposes on automobiles and kindred machines. Only those types that have been developed and put into commercial use are dealt with.

Magnetos, Aluminum in

British Made Magnetos. Elecn., vol. 82, no. 13, Mar. 28, 1919, pp. 348-349, 6 figs. Uses of aluminum in their manufacture. (Concluded.)

Magnetos, Experiments

Experiments on the High-Tension Magneto—I, Norman Campbell. London, Edinburgh and Dublin Phil. Mag., vol. 37, no. 219, Mar. 1919, pp. 284-301, 6 figs. Work conducted at Nat. Physical Laboratory under direction of Advisory Committee for Aeronautics. Results were kept confidential during time of war.

See also ELECTRICAL ENGINEERING, Varia (Insulation, Mica).

LIGHTING AND LAMP MANUFACTURE

Design

Chart to Facilitate the Design of Lighting System. Elec. World, vol. 73, no. 16, Apr. 19, 1919, pp. 778-779, 1 fig. Curves are based on illuminating intensity 3 ft. above floor; portion of diagram determining size of lamps necessary to produce intensified illumination: a depreciation of 30 per cent in light intensity due to dirt in reflector of lamp or deterioration of filament is assumed. From Indus. Lighting Code of Indus. Commission of Wisconsin.

Laboratories

Some Special Problems in the Lighting of Laboratories and Technical Institutions. Illuminating Engr., vol. 12, no. 1, Jan. 1919, pp. 13-16. Concerning lighting of blackboards and chemical, electrical and physical laboratories.

Office Lighting

Modern Practice in Office Lighting, A. Wise. Illuminating Engr., vol. 12, no. 2, Feb. 1919, pp. 27-39, 17 figs. Choice of methods for lighting and how these can be applied to various types of offices; importance of periodical cleansing of lamps and lighting units; illumination required for various classes of work; typical examples of installations.

Searchlights

The Searchlight Projector as Used in the Mercantile Marine, R. C. Harris. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 444-449, 15 figs. Types of lamps, mirrors and lenses and also methods of remote control, both mechanical and electrical.

Snellens Types

Report on Standard Illumination of Snellens Types Used in Testing the Vision of Candidates for Public Service. Illuminating Engr., vol. 12, no. 1, Jan. 1919, pp. 5-7, 2 figs. Report issued by Council of British Ophthalmologists. From British Jl. of Ophthalmology.

Street Lighting

Simple Lamp-Record System for Street Lighting Circuits, T. D. McDowell. Elec. Rev., vol. 74, no. 17, Apr. 26, 1919, pp. 668-669, 3 figs. Card records for noting type and history of lamps in use on large systems for street, boulevard or park lighting.

MEASUREMENTS AND TESTS

Fault Localizing

Fault Localizing: A Few Hints, H. Bujama. Electrical Review, vol. 84, no. 2160, Apr. 18, 1919, pp. 432-433, 5 figs. Double-slide wire bridge for use in connection with Murray loop and Varley loop tests.

Fuses

Short-Circuit Tests of Cartridge Fuses at the New York Office. Laboratories' Data, Underwriters' Laboratories, Nat. Board of Fire Underwriters, no. 1, Feb. 1919, pp. 16-19, 2 figs. Fuses were placed in cutout base, covered with thin layer of dry absorbent cotton and enclosed by strongly made protective cage; circuit breaker which was set so that it would not open automatically, but only by the cord, was then closed, and finally circuit was closed by switch at back of test frame.

Results of Factory Inspection of Standard Cartridge Enclosed Fuses. Laboratories' Data, Underwriters' Laboratories, Nat. Board of Fire Underwriters, no. 1, Feb. 1919, pp. 20-22, 1 fig. Graphs drawn from results of quarterly inspections.

Galvanometers, Differential

Zero Error in Differential Galvanometers (Über ein Differentialgalvanometer nebst einer Untersuchung über Nullpunktsfehler bei Drehspulengalvanometern), Helmer Bäckström. Zeitschrift für Instrumentenkunde, vol. 38, nos. 11 and 12, Nov. and Dec. 1918, pp. 173-179 and 189-195, 8 figs. Magnitude of after effect on zero position as affected by length of time during which deflection is maintained, damping of movement, and variations of current. Bibliography on moving-coil galvanometers covering period 1880-1916.

Ground and Short-Circuit Detection

Phase and Fault Testing by Means of Lamp Signals, Frank Gillooley. Elec. Rev., vol. 74, no. 16, Mar. 1919, pp. 617-619, 4 figs. Methods of using lamps in testing for grounds, short circuits and continuity of underground cables; methods of checking up phases and identification.

Hydrogen Overvoltage, Measurement of

Hydrogen Overvoltage, Duncan A. MacInnes and Leon Adler. Jl. Am. Chem. Soc., vol. 41, no. 2, Feb. 1919, pp. 194-207, 5 figs. Apparatus and method of measurement. It is concluded that hydrogen overvoltage is due primarily to a layer of supersaturated dissolved hydrogen in the electrolyte surrounding an electrode.

Insulator Testing

Pacific Coast Practice in Insulator Testing. Jl Electricity, vol. 42, no. 8, Apr. 15, 1919, pp. 345-347. Report of Insulator Committee of convention of Pac. Coast Section N. E. L. A.

Peak Potential, Measurement of

Note on the Measurement of the Peak Potential of an Alternating Source, Clifford C. Paterson and Norman Campbell. London, Edinburgh, and Dublin Phil. Mag., vol. 37, no. 219, Mar. 1919, pp. 301-303, 1 fig. Conditions which are considered necessary for accuracy in measuring peak potential by means of a thermionic valve.

Temperature, Body, Measurement

Some Notes on Electrical Methods of Measuring Body Temperatures, Robert S. Whipple. Electrical Review, vol. 84, no. 2158, Apr. 4, 1919, pp. 392-393, 5 figs. Adaptation of thermoelectric couples for measuring body temperatures; results of experiments. Paper read before Roy. Soc. of Medicine & Instn. of Elec. Engrs.

Temperature Determination by Weighing

Weighing High Temperatures in an Electric Balance, J. M. Bird. Sci. Am., vol. 120, no. 17, Apr. 26, 1919, pp. 430-431, 442 & 444, 5 figs. Curves for transformation points of two different steels, showing in each case the heating curve and the cooling curve. System of pyrometry based on use of thermocouples for controlling heat-treating furnaces in steel mills.

Timing

Accurate Timing in Electrical Tests, F. A. Kartak. Elec. World, vol. 73, no. 14, Apr. 5, 1919, pp. 672-675, 9 figs. Tuning-fork timing device found very satisfactory in practice, consists essentially of heavy iron base casting in head block of which are mounted two steel fork legs actuated by magnet; adjustment for rate of vigration is obtained by counterweights. Design was put into operation at Bur. Standard Laboratory.

Voltage Test Equipment

A Voltage Test Equipment. Laboratories' Data, Underwriters' Laboratories, Nat. Board of Fire Underwriters, no. 1, Feb. 1919, pp. 26-28, 1 fig. Outfit consists of transformer, the terminals of which are enclosed in glass case large enough to cover the device or sample under test.

Voltmeter, Electrostatic, Ayrton-Mather

New Measuring Instruments (Quelques nouveaux instruments de mesure), A. Tobler and K. Tchild. Journal Télégraphique, vol. 43, no. 3, Mar. 25, 1919, pp. 33-36, 7 figs. Ayrton-Mather electrostatic voltmeter as perfected by R. W. Paul. (To be continued.)

POWER APPLICATIONS

Cooking

Electric Cooking in Hotels, Clubs and Restaurants, C. O. Hard. Nat. Elec. Light Assn. Bul., vol. 6, no. 4, Apr. 1919, pp. 206-208, 3 figs. Section range with connected load of 30 kw.; 30-in. broiler connected load and other electrical features.

Mill Drive

Electrically Driven Plate Mills, G. E. Stoltz. Engrs.' Club of Philadelphia, vol. 36-1, no. 170, Jan. 1919, pp. 7-13, 10 figs. Considerations in selection of size and type of motor, control and flywheel, based on examination of performances of existing mills.

Electric Equipment in Blooming Mill of Steel Company of Canada, Hamilton. Elec. News, vol. 28, no. 8, Apr. 15, 1919, pp. 24-25, 2 figs. Generator set consists of 1800-hp., 2200-volt 3-phase wound rotor induction motor, a 50-ton flywheel and two 1200-kw., 600-volt d. c. generators all mounted on a common shaft.

Mine Service

Selection of the Electrical System, Voltage and Frequency for Mine Service, Terrell Croft. Coal Age, vol. 15, no. 15, Apr. 10, 1919, pp. 658-659. Believes that 500 volts is not an advisable tension to use at a coal mine, and advocates adhering to 250 volts as a standard.

See also MARINE ENGINEERING, Ships (Electric Propulsion), Yards (Electrical Equipment).

POWER GENERATION

Hydroelectric Plants

See items under Power Generation, Mechanical Engineering.

TELEGRAPHY AND TELEPHONY, RADIO

Detector, Radio-Frequency Oscillations

A Magnetic Detector of Radio Frequency Oscillations. Wireless Age, vol. 6, no. 8, May 1919, pp. 11-12, 4 figs. Based upon reputed principle that super-position of a high-frequency current upon iron core already excited by low-frequency current reduces hysteresis loop of low-frequency current.

Modulator, Mercury Vapor, Langmuir's

Langmuir's Mercury Vapor Modulator for Wireless Telephony. Wireless Age, vol. 6, no. 8, May 1919, pp. 15-16, 6 figs. Method of controlling output of radio frequency alternator at speech frequencies for radio telephony. Device comprises a glass or quartz envelope containing a body of mercury (constituting the cathode) and main anodes which may be made of graphite, tungsten, molybdenum or other highly refractory material.

Musical Radio-Sending

Notes on a Problem of Musical Radio-sending (in Japanese), T. Minohara. Denki Gakkwai Zasshi, no. 368, Mar. 10, 1919.

Progress Since 1914

Wireless Telegraphy and Telephony, J. A. Fleming. Times Eng. Supp., vol. 15, no 533, Mar. 1919, pp. 97-98. Progress since 1914.

Receivers, Bridge and Barrage

Simultaneous Sending and Receiving, E. F. W. Alexanderson. Wireless Age, vol. 6, no. 8, May 1919, pp. 23-26, 5 figs. Fundamental characteristics of the "bridge receiver" and the "barrage receiver." Paper read before Inst. Radio Engrs.

Regulations

Wireless Telegraphy and the Safety of Transoceanic Navigation (La télégraphie sans fil et la sécurité de la navigation maritime). Journal Télégraphique, vol. 43, no. 3, Mar. 25, 1919, pp. 36-38. Regulations of International Conference held at London on Nov. 12, 1913. (Concluded.)

Vacuum Tube

Negative Resistance Vacuum Tube as an Amplifier and a Beat Receiver. Wireless Age, vol. 6, no. 8, May 1919, pp. 12-13, 2 figs. Scheme using heterodyne principle to secure increased amplification and selectivity in receiving.

TELEGRAPHY AND TELEPHONY, WIRE

European Telephone Practice

European Telephone Practice, Fred W. Scholz. Telephone Engr., vol. 21, no. 4, Apr. 1919, pp. 159-163, 2 figs. Adaptation of telephone exchanges to telephone traffic. From Telegraphen-Versuchsamt. (To be continued.)

Telephone Receiver, Theory

Electromagnetic Theory of the Telephone Receiver with Special Reference to Motional Impedance, A. E. Kennelly and H. Nukiyama. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 4, Apr. 1919, pp. 491-539, 32 figs. Theory, which is stated under definite limitations, takes into account the m.m.f. produced by vibrations of diaphragm in permanent magnetic field; thus motional power is shown to be derived partly from testing alternating current and partly from changes in power of magnetic circuit.

See also ELECTRICAL ENGINEERING, *Generators and Motors (High-Frequency Generators).*

TRANSFORMERS, CONVERTERS, FREQUENCY CHANGERS

Instrument Voltage Transformers

Instrument Voltage Transformers, W. R. Woodward. Power, vol. 49, no. 15, Apr. 15, 1919, pp. 562-564, 11 figs. Westinghouse types.

Rectifiers

Transformation of Direct into Alternating Current, and Vice Versa, without a Commutator (Sur un système de transformation de courant continu en courant alternatif, et vice versa sans commutateur divisé), O. Li Gotti. Revue Générale de l'Electricité, vol. 5, no. 13, Mar. 29, 1919, pp. 471-484, 10 figs. Louis Magnini patented in 1905 (see Industrie Electrique, May 25, 1905, p. 217) an apparatus for rectifying an alternating current by the periodic alteration of the inductance coils mounted in two groups. In present article writer makes general study of possible transforming devices operating on induction phenomena.

Transformer Practice

Essentials of Transformer Practice—XXI, E. G. Reed. Elec. Jl., vol. 16, no. 4, Apr. 1919, pp. 145-147, 7 figs. Voltage transformations with auto-transformers.

TRANSMISSION, DISTRIBUTION, CONTROL

Control

The Control of Large Amounts of Power—III, L. B. Wedmore. Power House, vol. 13, no. 4, Apr. 5, 1919, pp. 97-101, 12 figs. Current-limiting by use of busbar reactance; heating and stresses due to heavy currents; combinations of machines requiring maximum transfer capacity; influence of power factor of machine on output of engine. Paper read before Inst. Elec. Engrs., England.

Cutout Bases

Effect of Cutout Base Design upon Plug Fuse Performance. Laboratories' Data, Underwriters' Laboratories, Nat. Board of Fire Underwriters, no. 1, Feb. 1919, pp. 23-25, 1 fig. Effect differences in cross-section have upon heating and consequently upon performance of plug fuses used in cutout bases.

Distribution, Flexibility

Flexible Distribution for Industrial Plants, L. F. Leurey. Elec. World, vol. 73, no. 17, Apr. 26, 1919, pp. 835-838, 7 figs. Design for meeting changing demands for power. Safety and low operating costs are said to be secured by employment of bus-bar feeders of uniform size.

Interconnection

Emergency Interchange of Power, G. R. Kenny. Jl. Electricity, vol. 42, no. 8, Apr. 15, 1919, pp. 347-349, 1 fig. Interconnection of two 60-cycle with one 50-cycle system. Paper presented by Eng. Committee for Pac. Coast Section N. E. L. A. convention.

Polyphase-Motor Protection

Protecting Polyphase Induction Motors from Single-Phase Operation, B. W. Jones. Power, vol. 49, no. 16, Apr. 22, 1919, pp. 604-606, 3 figs. Comparison of different means generally employed to prevent polyphase induction motors from operating single-phase and also from overheating.

Relays

Alternating-Current Plunger-Type Relays, Victor H. Todd. Power, vol. 49, no. 17, Apr. 29, 1919, pp. 636-639, 14 figs. Schematic diagram and characteristics of overload relay which obtains time limit by means of air bellows.

Relay Protective Systems, G. E. Armstrong. Jl. Electricity, vol. 42, no. 8, Apr. 15, 1919, pp. 349-353, 1 fig. Methods used on system of Southern Cal. Edison Co. From Eng. Report for spring convention of Pac. Coast Section N. E. L. A.

Synchronous Alternators

Stability of Synchronous Alternators in Constant-Potential System (Conditions de stabilité de la marche synchronique des alternateurs accouplés sur réseau à tension constante), A. Blondel. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 12, Mar. 24, 1919, pp. 587-593. Equation not taking into account oscillations induced in circuits of inductors is modified so as to include effect of these oscillations, and conditions necessary and sufficient for stability are obtained by application of Hurwitz' determinant.

Substation

Columbus Railway, Light & Power Co.'s Canal Street Substation, E. W. Clark. Elec. Rev., vol. 74, no. 17, Apr. 26, 1919, pp. 670-671, 6 figs. Switching arrangements and provision for voltage changeover.

Transformer Station, High-Tension

Transmission of Electrical Energy from Bourges to the American Arsenal at Beauvoir (Transmission d'énergie électrique de Bourges à l'Arsenal Américain de Beauvoir), Michel Berthon. Revue Générale de l'Electricité, vol. 5, no. 12, Mar. 22, 1919, pp 445-449, 3 figs. High-tension (70,000 volts) transforming station presented as example of rapidly established economic installation.

WIRING

City Hall Wiring

The Electrical Installation in San Francisco's City Hall. Elec. Rev., vol. 74, no 17, Apr. 26, 1919, pp 661-667, 7 figs. Features of conduit and wiring system for light, power, communication and signaling.

STORAGE BATTERIES

Barium Sulphate Action

Function of Barium Sulphate in Lead Accumulators (Sulla funzione del solfato di bario negli accumulatori a piombo), O. Scarpa. Elettrotecnica, vol. 6, no. 9, Mar. 25, 1919, pp. 176-179, 3 figs. Experimental research believed to have demonstrated that barium sulphate acts as negative catalyzer to transformation of lead.

Charging Plant

New Haven Installs Model Charging Plant. Ry. Elec. Engr., vol. 10, no. 4, Apr. 1919, pp. 103-106, 9 figs. Plant is equipped for charging, cleaning and repairing both lead and alkaline batteries and equipment and both 30- and 60-volt systems are taken care of.

Lead Acid Batteries

Characteristics of Starting and Lighting Batteries of the Lead Acid Type, O. W. A. Oetting. Elec. Jl., vol. 16, no. 4, Apr. 1919, pp. 134-139, 15 figs. Considerations in selecting size of starting battery.

Trickling Charge

The "Trickling Charge" as Applied to Lead-Acid Storage Batteries of the Naval Service, Lucius C. Dunn. U. S. Naval Inst. Proc., vol. 45, no. 193, Mar. 1919, pp. 339-343, 2 figs. Methods of applying to a charged storage battery a current just large enough to counteract local action and thus maintain it in a charged condition.

Civil Engineering

BRIDGES

Concrete Overhead Arch Bridges

Four Concrete Overhead Arch Bridges on Toronto-Hamilton Highway. Contract Rec., vol. 33, no. 14, Apr. 2, 1919, pp. 301-306, 6 figs. Governing factor in design of bridges has been long clearances by using parabolic overhead arch ribs braced together by horizontal bracing members.

Canada's Longest Reinforced Concrete Trusses. Can. Engr., vol. 36, no. 14, Apr. 3, 1919, pp. 345-348, 6 figs. Bridges carrying Toronto-Hamilton highway across Etobicoke river and Bronte creek. Each is 119 ft. clear span, with 20-ft. roadway and 16-ft. overhead clearance.

Canadian Reinforced Concrete Arch Bridges, Frank Barber. Can. Engr., vol. 36, no. 11, Mar. 13, 1919, pp. 289-293, 6 figs. Historical review and lists of open spandrel and earth-filled arches with clear span of over 100 ft. or total bridge length of over 200 ft.

Concrete-Pile Trestle Construction

Concrete Pile Trestle Construction, Albert M. Wolf. Eng. World, vol. 14, no. 8, Apr. 15, 1919, pp. 25-27, 6 figs. Economy of concrete pile process is argued by the fact that piles and slabs can be cast in central yard, and then transported to site and erected with comparatively small portable plants in the form of combined derrick and piledriver cars.

Construction

Railway Bridges in the Dutch Indies (Mededeelingen omtrent de verzwaring van den bovenbouw der bruggen in de lijn Goendih-Soerabajader Nederlandsch-Indische Spoorweg-Maatschappij), E. C. P. Hartman. De Ingenieur, vol. 34, no. 9, Mar. 1, 1919, pp. 148-161, 35 figs. Dismantling of old bridges and erection of new with aid of portable auxiliary bridges placed under existing structures on temporary pile foundation.

The Construction of Culverts and Small Bridges, Charles D. Snead. American City, Town & County Edition, vol. 20, no. 4, Apr. 1919, pp. 323-326, 2 figs. Methods suggested at Kentucky Road School.

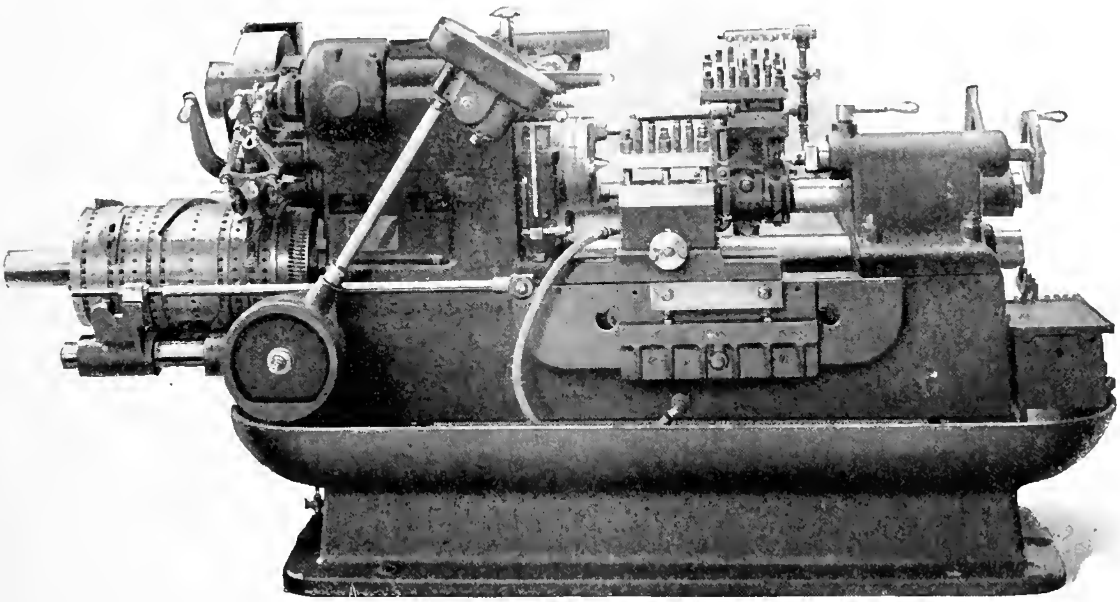
Failures

Are Our Highway Bridges Safe? Mun. Jl. & Public Works, vol 46, no 16, Apr. 19, 1919, pp. 276-279. Instances of failures of bridges. County highway officials quoted as saying that 30 per cent of bridges of the country are unsafe for heavy vehicles.

India

Adam's Bridge. Indian Eng., vol. 65, no. 1, Jan. 4, 1919, pp. 10-11, 1 fig. Project for connecting India and Ceylon by railway line.

The Fay Automatic Lathe



An automatic machine for simultaneous turning, facing and shouldering cuts on bar stock and centered forgings, such as pinion shafts, steering knuckles, cam shafts, etc.

An automatic machine for second operations on work held on centered arbors, such as spur and bevel gear blanks, hubs, pulleys, etc.

Designed with strength and driving power to carry all the tools, speed, and feed the work will stand under balanced cuts.

Jones & Lamson Machine Company

SPRINGFIELD, VERMONT, U. S. A.

109 Queen Victoria Street, London, E. C.

France, Spain and Belgium: F. Auberty & Co., 91 Rue de Maubeuge, Paris
Holland: Spliethoff, Beeuwkes & Co., Rotterdam

SEE OUR DATA IN 1918 A.S.M.E. CONDENSED CATALOGUES OF MECHANICAL EQUIPMENT

Lift Bridges

Pretoria Avenue Lift Bridge, Ottawa, L. McLaren Hunter. Contract Record, vol 33, no. 16, Apr. 16, 1919, pp. 355-356, 3 figs. Two 52½-ft. fixed spans and a central 95-ft. electrically operated direct-lift span giving 30 ft. maximum clearance.

Relieving Arches

Relieving Arches in Subway Distribute Stress to Piers. Eng. News-Rec., vol. 82, no. 14, Apr. 3, 1919, pp. 667-669, 7 figs. Feature of design in three-span subway carrying street is said to be arched sidewalk spans seated on haunches of roadway span in order to insure desired distribution of stress.

Strengthening Bridges

Strengthening Bridges for Truck Traffic. Contract Rec., vol. 33, no. 14, Apr. 2, 1919, pp. 318-319, also Good Roads, vol. 17, no. 14, Apr. 5, 1919, pp. 149-151. Report of Committee of Am. Road Builders' Assn. on methods of reconstruction to carry heavy loads.

BUILDING AND CONSTRUCTION

Chimney, Demolition

Demolishing Tall Brick Chimney, Ralph B. Chandler. Can. Engr., vol. 36, no. 16, Apr. 17, 1919, pp. 383-384, 3 figs. Plans and elevations of chimney, showing preparations for demolition with dynamite.

Coal Bins

An Example of Coal Bin Reconstruction, Wm. Joshua Barney. Coal Trade Jl., vol. 50, no. 17, Apr. 23, 1919, pp. 448-451, 7 figs. Reinforced concrete structure built to enlarge capacity. Bins continued in operation while structure was being erected.

Concreting Plant

Efficient Concreting Plant. Am. Contractor, vol. 40, no. 17, Apr. 26, 1919, p. 30, 1 fig. Mechanical dumping and distribution in construction of Hotel Fort Des Moines the erection of which was demanded by the Government to be urgently terminated.

Dams

See Earthwork, Rock Excavation, etc., p. 28a.

Dome, Reinforced-Concrete

The Reinforced Concrete Dome at Hippodrome, Copenhagen. Eng. & Contracting, vol. 51, no. 18, Apr. 30, 1919, p. 445, 2 figs. Notes on methods of construction.

Earthquakes

Effect on Structures of Recent Porto Rico Earthquakes, M. L. Vicente and C. F. Joslin. Eng. News-Rec., vol. 82, no. 17, Apr. 24, 1919, pp. 806-808, 5 figs. Investigations are represented as indicating that wood frame proves safest for buildings, with well-built reinforced concrete next, and articulated construction last.

Floor, Girderless

Notes on the Test of a Girderless Floor, Peter Gillespie and T. D. Mylrea. Jl. Eng. Inst. of Canada, vol. 2, no. 4, Apr. 1919, pp. 300-317, 22 figs. Tests conducted on flat slabs in Toronto factory by City Architect's Dept. in conjunction with Dept. of Applied Mechanics, University of Toronto.

Foundations

Mathematical Study of Foundations on an Elastic Soil (Etude mathématique des fondations sur terrain élastique), Keiichi Hayashi. Memoirs of the Coll. of Eng. Kyushu Imp. University, Fukuoka, Japan, vol. 1, no. 4, 1919, pp. 225-267, 18 figs. Three cases are considered: mass is loaded symmetrically with uniformly distributed weight; when there are central elevations; symmetrical loading with two concentric weights.

Flues, Chimney

Notes on Chimney Flues, Henry N. Dix. Am. Architect, vol. 115, no. 2259, Apr. 9, 1919, pp. 530-534, 6 figs. Causes of poor draft.

Houses

Philippine Island Concrete House. Concrete, vol. 14, no. 4, Apr. 1919, pp. 146-149, 14 figs. House is of concrete and steel, the only wood in the structure being used in framing for kitchen roof, window and door frames, for doors and windows, stair rail cap, dumb-waiter box and shelving in closets.

Recommendations for Inexpensive Houses. Contract Rec., vol. 33, no. 14, Apr. 2, 1919, pp. 308-311. Recommendations of Ontario Housing Committee.

House-Building Machinery

Labor-saving Machinery Used in Building Houses, Samuel H. Lea. Eng. News-Rec., vol. 82, no. 16, Apr. 17, 1919, pp. 753-755, 8 figs. Tractors for dragging plows and hauling concrete carts from central mixing plant to all parts of extended job.

Masonry

Studying the Defects in Masonry Structures. Ry. Maintenance Engr., vol. 15, no. 5, May 1919, pp. 167-168, 2 figs. On defects resulting from instability, disintegration and weathering.

Roofs, Brick-Arch

Thin Tied Flat Brick Arch Roofs, E. W. Stoney. Indian Eng., vol. 65, no. 6, Feb. 8, 1919, pp. 80-81, 16 figs. Experiments to determine strength of various tied arch ribs of 10 to 30 ft. span, 2 ft 3 in. wide, having rise of one-eighth span.

Schools

Standardization of Plans for Schools, Clarence E. Dobbin. Contract Rec., vol. 33, no. 15, Apr. 9, 1919, pp. 339-340. Points out that uniform practice in preparation of designs reduces office work and produces economies in cost without sacrificing architecture.

Construction and Equipment of Portable School Buildings—II, John Howatt and Samuel R. Lewis. Heat. & Vent. Mag., vol. 16, no. 4, Apr. 1919, pp. 34-39, 7 figs. Double-ceiled construction with paper between.

Skylight

New Type Skylight Saves Maintenance Expense. Contract Rec., vol. 33, no. 17, Apr. 23, 1919, pp. 392-393, 2 figs. Construction designed to make provision for expansion and contraction. Used at Windsor Station, Montreal, Can. Pacific Ry.

Sprinklers

Sprinkler Devices for Building Protection, F. C. Broadfoot. Contract Record, vol. 33, no. 16, Apr. 16, 1919, pp. 363-365. Advises frequent inspection or central station control.

Stairways

The Double Stairway, its Design and Construction. Am. Architect, vol. 115, no. 2260, Apr. 16, 1919, pp. 557-561, 16 figs. Schematic arrangements, dimensions and types of details.

Storage Tanks

Storage Tanks of Reinforced Concrete for Ammoniacal Liquors, F. W. Frerichs. Concrete, vol. 14, no. 4, Apr. 1919, pp. 151-154, 3 figs. Tanks were made from cement concrete consisting of one part cement, two parts sand and four parts gravel. Account is given of tests to which tanks were subjected with a view of ascertaining permeability of concrete by water and ammoniacal liquors.

The Admiralty Oil Fuel Reservoir at Rosyth. Petroleum Times, vol. 1, no. 12, Mar. 29, 1919, pp. 245-246, 3 figs. Reservoir is built of concrete on a rock foundation. Oil is pumped in or out by means of cast-iron oil mains.

Superintendence

Systematic Building Superintendence, Charles F. Dingman. Concrete, vol. 14, no. 4, Apr. 1919, pp. 159-162, 4 figs. Scheduling details of building construction; Flynt Company's "Standard practice instructions" to superintendents. (Concluded.)

CEMENT AND CONCRETE

Beams

A Simple Method for Designing Concrete Beams Reinforced for Compression, Arthur Raymond. Eng. & Contracting, vol. 51, no. 17, Apr. 23, 1919, p. 410, 2 figs. Simplifications introduced in general theory by approximating on safe side of formulæ.

Blasting Concrete

Blasting Concrete, S. R. Russell. Du Pont Mag., vol. 10, no. 5, May 1919, pp. 8-10, 5 figs. Suggestions in regard to drilling of holes and locating blasting cap. It is claimed that explosives can be used for breaking concrete with great economy of time and money and with absolute safety.

Concrete Mixtures

Saturation of Concrete Reduces Strength and Elasticity, M. B. Haggard. Cement and Eng. News, vol. 31, no. 4, April 1919, pp. 23-25, 6 figs. Compression tests made in experimental laboratory of University of Minnesota.

The Design of Concrete Mixtures. Eng. & Contracting, vol. 51, no. 17, Apr. 23, 1919, pp. 421-426, 5 figs. Interrelation of consistency, size and grading of aggregates, and the proportion of cement. Experimental research at Structural Material Research Laboratory, Lewis Inst., Chicago.

How to Design Concrete Mixtures, D. A. Abrams. Eng. News-Rec., vol. 82, no. 16, Apr. 17, 1919, pp. 758-763, 7 figs. Theory developed from tests; main principles of theory are: With given concrete materials and conditions of tests the quantity of water used determines strength of concrete so long as mix is of workable plasticity; measurement of aggregate grading on a sieve is of greatest importance in proportioning a mixture.

Depositing in Water

Depositing Concrete in Water. Contract Record, vol. 33, no. 16, Apr. 16, 1919, pp. 374-375. Report of Sub-Committee of Committee on Masonry of Am. Ry. Eng. Assn., presenting its opinion on best practice to be followed.

Design

Use Minimum Steel for Economy in Concrete Design, Albert M. Wolf. Concrete, vol. 14, no. 4, Apr. 1919, pp. 139-142, 2 figs. Tables giving sizes, percentages of steel and cost per foot of height for various columns.

Electrolysis

Electrolysis and Concrete—II. Railway Engineer, vol. 40, no. 471, Apr. 1919, pp. 67-69, 2 figs. Tests made at Mass. Inst. of Technology. Points investigated were: Action of stray currents on unstressed embedded steel; rate of corrosion of steel under stress; and, effect of setting cement on paint films. (Continuation of serial.)

Preservation, Concrete

The Preservation of Concrete Structures, Maxmilian Toch. Chem. Engr., vol. 27, no. 3, Mar. 1919, pp. 69-71. Methods in use for protecting concrete against errosion, chemical action, disintegration and decomposition. Address delivered before Am. Inst. of Chemical Engineers.

Solubility of Portland Cement

Solubility of Portland Cement and Its Relation to Theories of Hydration, J. C. Witt and F. D. Reyes. Eng. World, vol. 14, no. 7, Apr. 1, 1919, pp. 39-41. Investigation to determine what constitnents of cement will go into solution and the proportion of the total amount of each present in the sample.

EARTHWORK, ROCK EXCAVATION, ETC.

Cofferdam

Notes on the Design of a Single-Wall Cofferdam, F. R. Sweeny. Eng. News-Rec., vol. 82, no. 15, Apr. 10, 1919, pp. 708-711, 3 figs. Theoretic and economic considerations in developing size and location of timber walls and braces and steel sheeting.

Dams

Recent Development of Marin Water District, H. M. Bowers. Jl. Electricity, vol. 42, no. 7, pp. 316-318, 4 figs. Dam making use of siphon type of spillway.

Swift Rapids Dam and Ship Lift Lock. Contract Rec., vol. 33, no. 15, Apr. 9, 1919, pp. 330-333, 7 figs. Generating plant supplies current to Orillia, Ont., lock; plant is part of Trent Valley system.

Constrnction Methods Used at Drummondville, James Dick. Can. Engr., vol. 36, no. 17, Apr. 24, 1919, pp. 397-400, 7 figs. Damming of river and erection of power house to develop 19,000 hp.

Excavator, Tunneling

The Tunnelling Excavator. Iron & Coal Trades Rev., vol. 98, no. 2667, Apr. 11, 1919, p. 440, 1 fig. It is reported that under actual working conditions this patented machines has cut a tunnel 7 ft. 2 in. in diameter at average rate of 60 ft. in 24 hours.

Subway

Solving Construction Problems in Canal Street Subway, A. J. Mayell. Eng. News-Rec. vol. 82, no. 14, Apr. 3, 1919, pp. 650-652, 4 figs. Pit and drift methods used in construction work under old subway in New York City

Trench Digging

Municipal Work in Detroit. Fire & Water Eng., vol. 65, no. 18, Apr. 30, 1919, pp. 977-979, 3 figs. Trench digging and pipe laying by Water Dept. of city.

HARBORS

Copenhagen

Extension of Copenhagen Harbor (Forskelligt Jernbetonarbejde i og ved Københavns Havn). Teknisk Tidsskrift, vol. 42, no. 5

The Taylor Stoker

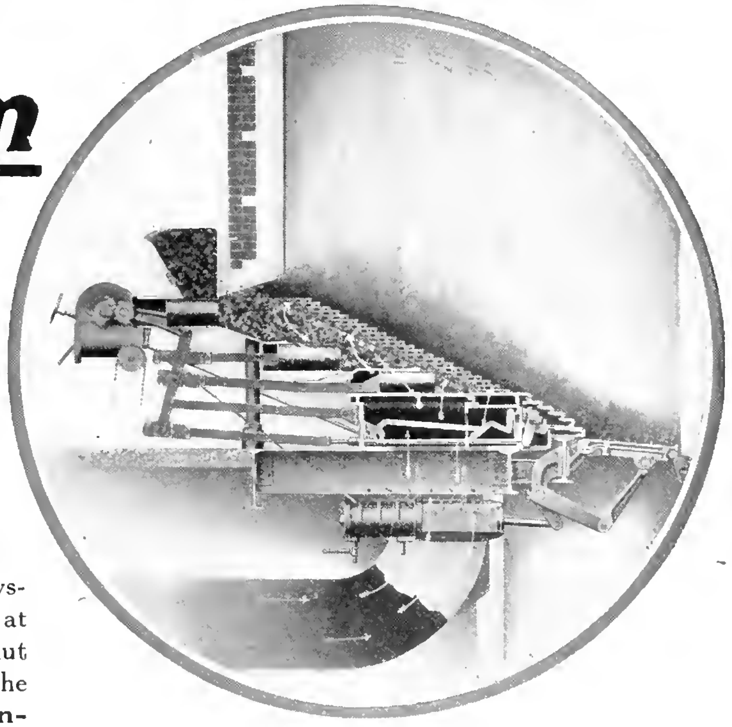
—more than a "Stoker"

A Complete SYSTEM of Scientific Combustion

How the

Taylor System

meets the 6 basic demands of boiler plant efficiency:



1-Continuous Steam Demand

The Taylor Stoker insures 24-hours-a-day, 365-days-a-year service. So long as you have the coal, at Taylor Stokered furnace need never be shut down except for periodical overhauling of the boiler. The fire is fed, sliced and cleaned **while running.** When you use a different grade of coal, you simply re-adjust tt e feed and the draft, accordingly—the operation goes on unceasingly. Clinker and ashes may be dumped by a mere lever movement. The "Fireman" never wearies, for he is freed from coal shoveling, from raking, slicing and battering at clinkers. And no matter whethe the steam demand jumps from 50% to 300% of the boiler capacity, the flexibility of the Taylor Stoker and the reserve power in the deep fuel bed make meeting it a matter of moments.

! Send for the new Taylor Stoker Catalog, Engineers' Edition

THE 6 DEMANDS

When the American Smelting and Refining Co. of Omaha, Neb., installed Taylor Stokers, these were their six boiler plant requirements:

1. Continuous operation
2. Minimum Labor
3. Utmost simplicity
4. Ready Accessibility
5. Maximum capacity
6. Provision for future plant growth

How Taylor Stokers meet these demands is told in this series of advertisements.

Æ CO

American Engineering Company

Philadelphia

Foreign Licensee: Babcock & Wilcox, Ltd., Oriel House, Farringdon Street, London, England

The TAYLOR System of Scientific Combustion

The Taylor Stoker

Dec. 18, 1918, pp. 6-7, 4 figs. Municipal electric power station adjoining harbor. Buildings and elevated railway for discharging coal to boiler house are of reinforced concrete. Part of quay wall consists of grooved reinforced-concrete piles and reinforced slabs.

Dock Gates

Reinforced Concrete Dock Gates. Engineer, vol. 127, no. 3299 Mar. 21 1919, pp. 289-290, 3 figs. Gates are constructed as stress line for uniform water pressure and are circular in shape; they have to stand a water pressure of 14 ft.

Montreal

Suggested Harbour Improvements for Greater Montreal. E. S. M Lovelace. Jl. Eng Inst of Canada, vol. 2, no. 4, Apr. 1919 pp. 318-327, 3 figs. To remedy strong current from canal basin to foot of island opposite Varennes; to provide sufficient depth at low water for larger ocean-going vessels; to prevent danger of floods during spring and fall.

Soerabaja, Java

New Harbor Works at Soerabaja, Java (Technische lessen en vraagstukken op het gebied van den Indischen havenbouw), Wouter Cool. De Ingenieur, vol. 34 no. 8, Feb. 22, 1919, pp. 121-141, 35 figs. Building of vertical reinforced-concrete quay walls on large caissons 22 ft. wide with 12 in. thick walls. Bases floated into position and sunk by being filled with concrete in bags.

Timber, Impregnated

Impregnated Timber for Harbors (Impraegnering af Havnetommer), A. Collstrop and Edv Bülow. Ingeniören, vol. 28, no. 11, Feb. 5, 1919, pp. 69-74, 17 figs. Results obtained in Denmark by impregnating pine and beech with tar oil.

Vancouver

Improvement of Vancouver Harbor. Contract Rec., vol. 33, no. 17, Apr. 23, 1919, pp. 381-386. Recommendations for development of port.

MATERIALS OF CONSTRUCTION

Clay

Experiments with Clay in its Relation to Piles, Alfred S. E. Ackerman. Surveyor, vol. 55, no. 1417, Mar. 14, 1919, pp. 213-224 and also Soc Engrs., Jl. & Trans., vol. 10, no. 2, 1919, pp 37-80 and (discussion), pp. 80-107, 17 figs. Results of 95 experiments, some extending over period of 40 hours each. Object was to determine relationship between horizontal pressure and depth at any given point in clay. Among other conclusions writer establishes that corrugating as well as tapering piles increases their resistance.

Tile

Strength of Hollow Building Tile. Eng. & Contracting, vol. 51, no. 17, Apr. 23, 1919, pp. 411-415, 6 figs. Tests conducted by Bureau of Standards. From Technologic Paper no. 120.

RECLAMATION AND IRRIGATION

Drainage Work

Moore Park Drainage System, Toronto, W. G. Cameron. Can. Engr., vol. 36, no. 9, Feb. 27, 1919, pp 251-255, 7 figs Storm-water outlet; district drained comprises area of 2375 acres.

Drainage Works on Railway Lands, G. A. McCubbin. Can Engr., vol. 36, no. 11, Mar. 13, 1919 pp. 295-298. Dominion laws in respect to drainage and examples of their application. Paper read at Annual Meeting of Assn. of Ontario Land Surveyors.

ROADS AND PAVEMENTS

Accounting

County Highway Books and Bookkeeping, Gordon F Daggett. American City, Town & County Edition, vol 20, no. 4, Apr. 1919, pp. 327-330, 3 figs. Forms for county highway departments.

Brick Pavements

Present Status of Brick Pavements Constructed with Sand Cushions, Cement Mortar Beds and Green Concrete Foundations, W M. Acheson. Good Roads, vol. 17, no. 14, Apr. 5, 1919, pp. 147-149, also Contract Record, vol. 33, no. 16, Apr. 16, 1919, pp. 370-371. Comparison of old and new methods of constructing brick pavements with reference to strength and durability.

Chicago Boulevards

The Michigan Avenue Improvement is the Most Important Addition to Chicago's Boulevard System, Hugh E. Young. Eng. World, vol. 14, no. 8, Apr. 15, 1919, pp. 15-24, 7 figs. Construction of work to remedy congestion in traffic which will involve expenditure of $7,700,000.

Concrete Roads

Machine Finishing Concrete Roads, E. G. Carr. Mun. & County Eng., vol. 56, no. 4, Apr. 1919, pp. 132-134, 5 figs. Benefit of using machine by reason of compactness resulting from action in concrete mass.

Drains

Segment Blocks have Advantages on Larger-Size Drains, D. L. Yarnell. Eng. News-Rec., vol. 82, no. 14, Apr. 3, 1919, pp. 663-664. Report prepared under direction of Bur. Public Roads and Rural Eng. Advantages of lightness, ease of handling and small breakage.

Financing

Methods of Financing Highway Improvements for States, Counties and Towns. Good Roads, vol. 17, no. 17, Apr. 26, 1919, pp. 177-179. Committee report presented at Convention of Am. Road Builders' Assn.

Grade Separation

General Problems and Aspects of Grade Separation. Eng. & Contracting, vol. 51, no. 16, Apr. 16, 1919, pp. 381-384. Report issued by Div. of Grade Separation and Bridges of city of Detroit. It comprises partly an account of progress and partly a study of general and special problems with which city is confronted as it looks forward to an extensive program of construction.

Guarantees

Pavement Guarantees. Can. Engr., vol. 36, no. 13, Mar. 27, 1919, pp. 337-339. Report of Committee on "Economic Status of Guarantees of Pavements on Roads and Streets," presented Feb. 28, at the Annual Convention of Am. Road Builders' Assn.

Indian Roads

Metalling Roads in the Punjab, Khan Bahadur M. Abdul Ahad. Indian Eng., vol. 65, no. 9, Mar. 1, 1919, pp. 124-125, 1 fig. Substitutes introduced by Punjab road engineers are: Sarai-Kala limestone, stone boulders, shingle and shale and overburnt brickbats.

Macadam

Considerations Affecting Designs of Heavy Traffic Highways in Ontario, W. A. McLean. Mun & County Eng., vol. 56, no. 4, Apr. 1919, pp. 157-158. Table indicating required thickness of macadam road crust to transmit at an angle of 30 deg. from the vertical safe bearing pressure to subgrade of various soils. From annual report of Ontario Dept. of Highways.

National Roads

National Roads, E. A. Kingsley. Mun. Jl. & Public Works, vol. 46, no. 16, Apr. 19, 1919, pp. 293-294. Argument in their favor based on success of Nat. Administration of French Roads.

Oil-Heating Plant

Road-Oil Heating Plant of Los Angeles County, E. Earl Glass. Eng News-Rec., vol. 82, no. 15, Apr. 10, 1919, pp. 728-730, 3 figs. Built plant from old equipment in stock. Installation is said to save county $20 per 1,000-gal. tank.

Relocations

Highway Relocations, Gordon F. Daggett. Wisconsin Engr., vol. 23, no. 7, Apr. 1919, pp. 235-243. In relation to securing a more economical road as regards construction and maintenance features.

Scarifier

A New Road Scarifier. Engineer, vol. 127, no. 3298, Mar. 14, 1919, p. 254, 4 figs. A quick-lift toggle action is fitted to frame carrying tines. This permits carrying out of tines to full depth on both sides of an obstruction.

Snow Removal

Efficient Methods of Snow Removal from Highways Outside of Urban Districts. Good Roads, vol. 17, no. 17, Apr. 26, 1919, pp. 180 & 187. Committee report presented at Convention of Am. Road Builders' Assn.

Truck Transportation

Hard Surface Roads and the Auto Truck, H. W. Eldridge. Cement & Eng. News, vol. 31, no. 4, Apr. 1919, pp. 28-29, 1 fig. Transportation of war supplies from point of production in interior states to points of shipping on Atlantic Coast.

Bituminous Surfaces under Truck Traffic, Prevost Hubbard. Contract Rec., vol. 33, no. 14, Apr. 2, 1919, pp. 314-315. Firm foundation essential to resist action of heavy motor trucks.

Wood-Block Pavements

Some Specific Suggestions on the Design and Construction on Modern Wood Block Pavements, E. A. Fisher. Mun. & County Eng., vol. 56, no. 4, Apr. 1919, pp. 129-130, 4 figs. Laying block on pitch cushion applied to smooth concrete base and filling in the remainder with sand.

See also MUNITIONS AND MILITARY ENGINEERING, Roads.

SANITARY ENGINEERING

New Orleans System

Unique Feature of Unified Operation of Water, Sewerage and Drainage Facilities at New Orleans, La., George G. Earl. Mun. & County Eng., vol. 56, no. 4, Apr. 1919, pp. 121-129, 3 figs. Developments which are said to have reduced death rate of city about one-third.

Refuse Collection

Efficiency in City Scavenging. Mun. Jl. & Public Works, vol. 46, no. 17, Apr. 26, 1919, pp. 309-311, 3 figs. Suggestions for planning a system of refuse collection.

Refuse Disposal

Refuse Disposal in London. Mun. Jl. & Public Works, vol. 46, no. 15, Apr. 12, 1919, pp. 263-264. Borough of 120,000 population reported to have screened its refuse, recovered paper and other salable materials and used a clay pit for dumping.

Sewage Disposal

Design Features of Sewage Disposal Plant at Industrial Housing Development of the Alan Wood Iron and Steel Co., at Swedeland, Pa., George L. Robinson. Mun. & County Eng., vol. 56, no. 4, Apr. 1919, pp. 135-136, 1 fig. Sections of sliding tanks.

Sewage Disposal in North Dakota, Elwyn F. Chandler. Quarterly Jl. of the Univ. of North Dakota, vol. 9, no. 3, Apr. 1919, pp. 220-230. Lists for North Dakota and the Red River Valley those towns that are on the banks of rivers and that already have (or will shortly have) sewerage systems, and formulates conclusions concerning the population that each may reach before its sewer outfall will transform the stream into a possible nuisance.

Regulating Chlorine Doses. Mun. Jul. & Public Works, vol. 46, no. 15, April 12, 1919, pp. 264-265. Conclusions from experiments by Maryland Health Dept. Five-minute absorption test recommended.

The Disposal of Sewage by Treatment with Acid, Edgar S. Dorr and Robert Spurr Weston. Boston Soc. Civil Engrs., vol. 6, no. 4, Apr. 1919, pp. 145-166 and (discussion) pp. 166-175. Concludes from results of various experiments and studies that the Miles process will produce a well disinfected effluent from which 90 per cent of the settleable solids have been removed.

Sewage Disposal by Dilution, Including Chlorination of Sewage Effluent and Treatment of Sludge, W. C. Easdale. Surveyor, vol. 55, nos. 1418 and 1419, Mar. 21 and 28, 1919, pp. 227-229 and 244-246, 2 figs. also Eng. & Contracting, vol. 51, no. 18, Apr. 30, 1919, pp. 456-459, 2 figs. Concerning removal of maximum percentage of solids in suspension; maintenance of sewage in fresh condition while passing through tanks; treatment of sludge in such a manner as to facilitate its disposal without causing fouling of tank effluent.

Sewage, Measuring Devices for

Sewage System for Essex Border Cities. Contract Record, vol. 33, no. 16, Apr. 16, 1919, pp. 358-362, 3 figs. Regulating chambers and measuring devices.

Sewage Pumping

Milwaukee Sewage Pumping Station, T. Chalkely Hatton. Fire & Water Eng., vol. 65, no. 17, Apr. 23, 1919, p. 938, 3 figs. Automatically controlled system for disposing of maximum combined daily flow of 231,000,000 gal.

Sewage Screening

Grit Chamber and Fine Screens for Part of New York Sewage, Charles E. Gregory. Eng. News-Rec., vol. 82, no. 14, Apr. 3, 1919, pp. 672-674, 5 figs. Screens of revolving-disk type. Plant serves an area of 345 acres of which about 17 per cent is built up with apartment houses.

Sewers

Equipment and Methods Employed in Building Sewers in San Francisco, Cal., H. W. Shimer. Mun. & County Eng., vol. 56, no. 4, Apr. 1919, pp. 136-140, 18 figs. Disposal scheme adopted is to discharge sewerage only at points were there are strong tidal currents.

Storm Sewer Extension at Toronto Harbor, George T. Clark. Can. Engr., vol. 36, no. 6, Feb. 6, 1919, pp. 193-195, 4 figs. Drainage problems arising from waterfront improvements and how they are being solved.

Town Planning

Town Planning in Canada, James White. Can. Engr., vol. 36, no. 6, Feb. 6, 1919, pp. 199-200. Outline of work of Commission of Conservation in relation to housing and land problems

SURVEYING

Azimuth Line

Drawing the Azimuth Line (Tracciamento della retta d'azimut), E. Modena. Revista Maritima, vol. 52, no. 2, Feb. 1919, pp. 169-173, 1 fig. Method is similar to St. Hilaire's for altitude line.

Geometric Leveling

Geometric Leveling by the Method of Dr. Wilhelm Seibt (Nivelacion geométrica par el metodo del Dr. Wilhelm Seibt), Tomas González Roura. La Ingenieria, vol. 23, no. 6, Mar. 16, 1919, pp. 379-388. Probable error of an isolated observation. (Continuation of serial.)

Transit

Variations of the Optical Axis of a Transit (Sur l'étude des perturbations de l'axe optique d'une lunette méridienne en direction), Maurice Hamy. Comptes Rendus des Séances de l'Académie des Sciences, vol. 168, nos. 9 and 10, Mar. 3 and 10, 1919, pp. 429-435 and 484-489, 4 figs. Adjustment of telescope by means of collimator placed in line of axis of rotation and two double-reflection prisms placed near ends of collimator and telescope which permit illuminated opening of collimator to be viewed through eyepiece of telescope. Formulæ for corrections. Determination of coefficients entering in equations given in first part of article (Comptes rendus, vol. 168, Feb. 24, 1919.)

WATER SUPPLY

Dry Feeding

The Dry Feeding of Chemicals Used in Water Purification, F. B. Leopold. Mun. & County Eng., vol. 56, no. 4, Apr. 1919, pp. 134-135, 1 fig. Main feature of dry-feed apparatus is cast-iron housing, into which is fitted a drum wheel carrying material forward through an adjustable orifice.

Earthquake Protection

San Francisco's High-Pressure Water Supply, Charles W. Geiger. Eng. World, vol. 14, no. 8, Apr. 15, 1919, pp. 29-32, 6 figs. Safeguards to protect system from damage by earthquakes or accidents.

Factory Water Supply

What it Pays to Know About Factory Water Supply—II, Charles L. Hubbard. Factory, vol. 22, no. 4, Apr. 1919, pp. 689-692, 4 figs. Bringing water to the plant.

Filter Plant

Dundas Has New Filter Plant on Gravity Supply, E. H. Darling. Can. Engr., vol. 36, no. 16, Apr. 17, 1919, pp. 379-382, 6 figs. Concrete dam forms conservation reservoir. Plant has capacity of 700,000 imp. gal. a day.

Manzanares River

Embankment and Hygienic Treatment of the Manzanares River (Encauzamiento y saneamiento del rio Manzanares), Edwardo Fungairino. Revista de Obras Públicas, vol. 67, no. 2268, Mar. 13, 1919, pp. 121-126, 10 figs. Reinforced-concrete structures being erected.

Montana

Treating Montana Waters, C. Herschel Koyl. Ry. Maintenance Engr., vol. 15, no. 5, May 1919, pp. 154-157, 2 figs. Results yielded by installation of Great Northern Railway for treating waters on 1100 miles of main lines.

Purification

Water Purification. Times Eng. Supp., vol. 15, no. 533, Mar. 1919, pp. 104-105. Methods and aims

Softening

Lime Softening of Water and the Use of Sludge as an Aid, W. A. Sperry. Can. Engr., vol. 36, no. 16, Apr. 17, 1919, pp. 384-386 also Eng. & Contracting, vol. 51, no. 15, Apr. 9, 1919, pp. 364-365. Experience at Grand Rapids with changing seasons and illustrating the relations of time and temperature. Paper read before Illinois Section Am. Waterworks Assn.

Treating Water Reduces Boiler Troubles, C. Herschel Koyl. Ry. Age., vol. 66, no. 17, Apr. 25, 1919, pp. 1053-1056, 2 figs. Great Northern experiences with installation on 1100 miles of main lines.

Water Softening: Investigation; Features of Plant; and Special Problems of Large Installations, M. F. Stein. Eng. & Contracting, vol. 51, no. 15, Apr. 9, 1919, pp. 353-356, 5 figs. Results of investigation for softening Lake Erie water. A diagram shows ultimate composition of water after treatment with various amounts of lime. Paper read before Illinois Section of Am. Waterworks Assn.

Under-Water Mains

Water Main Under Copenhagen Harbor (Vandledning nnder Havnen til Sundbyerne). Ingeniören, vol. 27, no. 101, Dec. 18, 1918, p. 634. Project for increasing water supply to suburb where rapid growth has made present supply insufficient.

Wells

Methods of Drilling and Test Results of Large Capacity Well. Eng. & Contracting, vol. 51, no. 15, Apr. 9, 1919, pp. 362-363, 3 figs. Data secured at University of Illinois Wells.

WATERWAYS

Flood Control

Flood Control Work in Washington, W. A. Scott. Eng. World, vol. 14, no. 7, Apr. 1, 1919, pp. 23-28, 12 figs. Project involving expenditure of $1,500,000.

Hell Gate Channel

Industrial Influence of Waterways, Harry Chapin Plummer. Indus. Management, vol. 57, no. 5, May 1919, pp. 353-358, 5 figs. How improvement of Hell Gate Channel and Harlem River will affect eastern manufacturers.

Rivers

Formation of Sinuosites in Water Courses (Recherches sur la formation des sinuosités des cours d'eau), C. Hoc. Génie Civil, vol. 74, no. 12, Mar. 22, 1919, pp. 233-234, 7 figs. Theory of meander of rivers developed from study of dynamic condition of moving point in liquid, considered as subjected to system of elastic forces defined by ellipsoid of elasticity. (Concluded.)

Mining Engineering

BASE MATERIALS

Asbestos

Famous Mineral Localities: The Pelham Asbestos Mine, Massachusetts, Earl V. Shannon. Am. Mineralogist, vol. 4, no. 4, Apr. 1919, pp. 37-39. Characteristical feature is granular material, olivine colored dark by magnetite or chromite dust, containing scattered square phenocrysts of bronzy enstatite up to 3 cm. in length, the whole forming a typical fresh saxonite.

Building Rock

Mineral Deposits and Building Rock Beds of the Argentine Republic (Los yacimientos de minerales y rocas de aplicación en la República Argentina), Ricardo Stappenbeck, Ministerio de Agricultura de la Nación, Direction General de Minas, Geologia e Hidrologia, boletin no. 19, series B, 1918, 107 pp. 1 fig. Summary of notes gathered by various explorers, particularly on genetic formation of ore deposits.

Graphite

Preliminary Report of an Investigation into the Concentration of Graphite from Some Ontario Ores. Can. Min. Jl., vol. 40, no. 12, Mar. 26, 1919, pp. 189-197, 11 figs. Account of experimental work conducted by staff of Dept. of Min. Eng., University of Toronto. From results of tests a system of concentration was outlined.

Lime

The Lime Industry in 1918. Cement & Eng. News, vol. 31, no. 4, Apr. 1919, pp. 35-38. General condition and statistics of production.

COAL AND COKE

Accidents

Reducing Accidents in Coal Mining, Charles P. McGregor. Coal Indus., vol. 2, no. 4, Apr. 1919, pp. 149-150. Duties of officials with reference to inspections, visits, discipline and machinery.

By-Product Plants

Some Striking Features of a Byproduct Coke Plant. Coal Age, vol. 15, no. 15, Apr. 10, 1919, pp. 654-657, 7 figs. Boosters are used to increase pressure of coke-oven gas after by-products are extracted.

Going In for the Production of By-Products Linked with many Important Considerations, L. W. Alwyn-Schmidt. Am. Gas Eng. Jl., vol. 110, no. 15, Apr. 12, 1919, pp. 309-311. Observes that production of by-products can not be neglected by small gas works.

Research and Progress in By-Product Coking in Great Britain—IV, John B. C. Kershaw. Coal Age, vol. 15, no. 17, Apr. 24, 1919, pp. 752-756, 6 figs. Coals are usually crushed and mixed before coking. Arrangement of coke oven plant at Newton Chambers & Co. collieries is given as example of practice followed.

Canada

Coal Resources of Western Canada—I, James White. Coal Age, vol. 15, no. 17, Apr. 24, 1919, pp. 744-748, 3 figs. Distribution: analysis of coal samples; production of coal in Alberta during 1917. (To be concluded.)

Classification

The German System of Coal Classification and the Future Economic War—III. Colliery Guardian, vol. 117, no. 3038, Mar. 21, 1919, pp. 660-661. It is presumed that future economic war will involve restriction of freedom of mine owner in respect of winning and treatment of coal, by introduction of methods based on communal economics.

Coke-Oven Gas

Coke-Oven Gas. Colliery Guardian, vol. 117, nos. 30-40, Apr. 4, 1919, pp. 773-774. Future development of coking industry will take place, writer believes, in two main directions: coke-oven plants becoming large heat, light and power producers, or becoming large centers of chemical activity.

Cutter

Coal-Cutter Invented by a Working Miner. Iron & Coal Trades Rev., vol. 98, no. 2666, Apr. 4, 1919, p. 415, 2 figs. Sketch plan showing details.

Gas

Bumps and Outbursts of Gas in the Crewsnest Pass Coal Field. Coal Age, vol. 15, no. 15, Apr. 10, 1919, pp. 660-665, 5 figs. Field covers 230 square miles and is estimated to contain 845 billion tons of coal. From Bul. 2, 1918, British Columbia Department of Mines.

Kent Coalfield

The Evolution and Development of the Kent Coalfield, A. E. Ritchie. Iron & Coal Trades Rev., vol. 98, nos. 2661, 2664, 2665, 2666, 2667, Feb. 28, Mar. 21, 28, Apr. 4, 11, 1919, pp. 257-258, 356, 381, 414, and 447-448, 3 figs. From 1897 to 1900. Mar. 21: Nationalization of Westphalian Coal Syndicate from accounts in German newspapers. Mar. 28: from 1912 to 1918. Apr. 4: from 1901-1905. Apr. 11: Diagram of borings put down by Kent Coal Concessions, Ltd., up to Dec. 1906.

Spanish Industry

Geological History of Coal and Its Present Value. II. Actual Conditions of Spanish Coal Industry; Its Future (La hulla en el pasado geológico y en el presento histórico. II Estado actual de la industria hullera española; su porvenir), D. Pablo Fábrega. Revista Minera, vol. 70, no. 2680, Mar. 16, 1919, pp. 129-135. Presentation of various theories concerning origin of coal; comparison of activities in coal industries of various nations. Conference given before Instituto de Ingenieros Civiles.

Stripping

Coal Stripping in the United States—IV, Wilbur Greeley Burroughs. Coal Indus., vol. 2, no. 4, Apr. 1919, pp. 143-146, 6 figs. Features of stripping and loading shovels and dragline excavators.

Methods of Mining Coal. W. C. Boehert. Pahasapa Quarterly, vol. 8, no. 2, Feb. 1919, pp. 41-52, 7 figs. Practices followed in U. S. A. in connection with stripping or open-cut mining, and mining under ground or under cover.

Surface Support

The Effect of Coal Mining on the Overlying Rocks and on the Surface, W. D. Lloyd. Colliery Guardian, vol. 117, no. 3041, Apr. 11, 1919, pp. 837-839 and (discussion) p. 842. Writer indicates lines on which he believes further observations should be made on the effect mining operations will have on the support of the surface. Paper read before Midland Inst. Min., Civil & Mech. Engrs.

Transportation

The Carriage of Coal by Rail in India. H. Kelway-Bamber. Ry. Gaz., vol. 30, no. 14, Apr. 4, 1919, pp. 603-605, 6 figs. Development in Indian coal output and forecast of future coal consumption. (To be continued.) Paper read before Indian Section, Roy. Soc. of Arts.

See also INDUSTRIAL TECHNOLOGY, By-Products, Coal By-Products.

GEOLOGY AND MINES

Adirondack Region

Pegmatite, Silextite, and Aplite of Northern New York. William J. Miller. Jl. Geology, vol. 27, no. 1, Jan-Feb. 1919, pp. 28-54, 8 figs. Examination of accepted genetic theories in view of phenomena presented by occurrences in Adirondack region.

Alaska

The Nelchina-Susitna Region, Alaska, Theodore Chapin. Dept. of the Interior, U. S. Geol. Survey, bul. 668, 1919, 67 pp., 14 figs. Location, area and geology of drainage basins of Copper and Susitna Rivers.

American Geology, Bibliography of

Bibliography of North American Geology for 1915 with subject index, John M. Nickles. Dept. of Interior, U. S. Geol. Survey. Bul. 645, 1916, 144 pp. Includes publications bearing on the geology of the Continent of North America and adjoining islands; also Panama and the Hawaiian Islands. Textbooks and papers general in character by American authors are included; those by foreign authors are excluded unless they appear in American publications.

Argentina

Geological and Hydrogeological Studies in the Region between the Mouth of the Rio Negro, San Antonio, and Choele-Choel (Estudios geológicos e hidrologicos en la región comprendida entre Boca del Rio Negro, San Antonio y Choele-Choel), Ricardo Wichmann. República Argentina, Anales del Ministerio de Agricultura de la Nación, Seccion Geológica, Mineralogia y Mineria, vol. 13, no. 3, 1919, 44 pp., 5 figs. Data secured in survey of region.

Contribution to the Geology of the Argentine Republic (Contribución al conocimiento geológico de la República Argentina), Ricardo Wichmann and Franco Pastore. Anales del Ministerio de Agricultura de la Nación, Sección Geologia, Mineralogia y Mineria, vol. 13, no. 4, 1919, 45 pp. 8 figs. Geology of region between Rio Negro and Arroga Valcheta, with petrographic description of volcanic and metamorphic rocks.

British Columbia

Was there a "Cordilleran Glacier" in British Columbia? J. B. Tyrell. Jl. Geology, vol. 27, no. 1, Jan.-Feb. 1919, pp. 55-60. Writer's observations have led him to deny possibility of existence of a great longitudinally moving Cordilleran glacier in latitude 54 deg., and he believes that it was absent as far south as Quesnel in latitude 53 deg.

Crystallography

Crystallography of Some Canadian Minerals: 8 Axinite. Eugene Poitevin. Am. Mineralogist, vol. 4, no. 4, Apr. 1919, pp. 32-36. Analyses made by Geol. Survey of Canada. Gives table showing combination of forms on nine measured crystals.

Dakota, North

The Geology of North Dakota, A. G. Leonard. Jl. Geology, vol. 27, no. 1, Jan.-Feb. 1919, pp. 1-27, 2 figs. Rocks are classified as being chiefly clays, shales and sandstones belonging to the Cretaceous and Tertiary periods, overlain in most places by the drift deposits of the Pleistocene.

Economic Geology

Contributions to Economic Geology (Short papers and preliminary reports), part II, Mineral Fuels, M. R. Campbell and David White. Dept. of Interior, U. S. Geol. Survey, Bul. 621, 1916, 375 pp., 42 figs. Descriptions of occurrences that have economic interest but are not considered of sufficient importance to warrant an extended account; preliminary reports on economic investigations, the results of which are to be published later in more detailed form; apparatus for determining percentage of ash and coal and instructions for its use.

Idaho

A Preliminary Report on the Mining Districts of Idaho, Thomas Varley, Clarence A. Wright, Edgar K. Soper and Douglas C. Livingston. Dept. of Interior, Bur. of Mines, Bul. 166, 113 pp., 6 figs. Gives localities of mining districts, and nature of present operations and those that have been carried on in the past; geology is discussed in reference to types of ore deposits and character of ores.

Lava

Dacites and Dacitoides, With Reference to Lavas of Martinique (Dacites et dacitöides, à propos des laves de la Martinique), A. Lacroix. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 6, Feb. 10, 1919, pp. 297-302. Composition of volcanic rocks found in Martinique is adduced in support of theory that a number of lavas, which are considered as andesites, are in reality heteromorphic dacites.

Metalliferous Deposits

Original Formation of Metalliferous Deposits (Sur la formation originelle des gisements métallifères). Notes Provençales (Notes de géophysique), no. 7, Feb. 1919, pp. 18-21. On the genesis of exogenous deposits. Remarks on Stephen Tabor's paper, The Mechanics of Vein Formation, before Am. Inst. Min. Engrs. See Trans., A. I. M. E., Sept. 1918, pp 1189-1222.

Nevada

The Yerington District, Nevada, Adolph Knopf. Min. & Sci. Press, vol. 18, no. 14, Apr. 5, 1919, pp. 455-458, 2 figs. Geological records; analysis of limestone sample taken in district. From Professional Paper 114, U. S. Geol. Survey.

Texas

Geology of North Central Texas Field, Wallace E. Pratt. Oil & Gas Jl., vol. 17, no. 44, Apr. 4, 1919, pp. 54-56. Structure of surface beds; surface relation to subsurface; occurrences of water, oil and gas. Paper before Am. Assn. of Geologists.

Vancouver Island

Sooke and Duncan Map-Areas, Vancouver Island, C. H. Clapp. Can Dept. of Mines, Geol. Survey, memoir 96, 445 pp., 19 figs. Topography, geology and natural resources.

IRON

Mesabi Range

Iron-Ore Concentration on the Mesabi Range, F. A. Kennedy. Eng. & Min. Jl., vol. 107, no. 16, Apr. 19, 1919, pp. 683-688, 5 figs. Tables and curves relating to performances of washers; suggestions for betterment of present methods.

LEAD, ZINC, TIN

Tin Mining

Tin-Mining in the Dutch Indies (Van het handgrondwerk naar het spuit-en pompbaggerbedrijf), J. C. Mollema. De Ingenieur, vol. 34, no. 5, Feb. 1, 1919, pp. 68-79, 14 figs. Particulars of a number of installations.

Zinc-Ore Distillation

Refractories for the Zinc Industry, M. Grover Babcock. Jl. Am. Ceramic Soc., vol. 2, no. 2, Feb. 1919, pp. 81-95. Requirements of clay retorts used in distillation of zinc ores.

Zinc-Ore Mining

Operations at the Zinc Camp, Arkansas, Tom Shiras. Eng. & Min. Jl., vol. 107, no. 14, Apr. 5, 1919, pp. 607-608, 2 figs. Mining confined to removal of siliceous ores.

MAJOR INDUSTRIAL MATERIALS

Manganese

Chrome and Manganese Ores in Cuba. Boletin de Minas, no. 5, 1918, pp. 57-70. Despite handicaps, it is believed that the outlook for a steadily increasing production in 1918 and 1919 is good. Reserves of manganese are estimated at 700,000 to 800,000 tons. The Spanish text for this article appears in pp. 41-56. From U. S. Geol. Survey, bul. 380, Sept. 1918.

Report on the Manganese Deposits of Georgia (Second Report on Manganese), J. P. D. Hull, Lawrence la Forge and W. R. Crane. Geol. Survey of Georgia, bul. 35, 295 pp., 39 figs. Divided into three parts. (1) relation of ore deposits to structural geology, (2) description of individual properties and mode of occurrence of ore, and (3) methods of mining and cleaning ore. Prepared in cooperation with U. S. Geol. Survey and U. S. Bur. of Mines.

The Mining and Preparation of Manganese Ores in Tennessee, W. R. Crane and E. R. Eaton. Mining Jl., vol. 125, no. 4363, Apr. 5, 1919, pp. 213-214. Minerals found are pyrolusite, psilomelane, and manganite. (To be continued.) From Mag. of Tennessee Geol. Soc.

Manganese, T. G. Trevor, South African Jl. Industries, vol. 2, no. 1, Jan. 1919, pp. 35-43. Occurrence and appearance of ores; metallurgical and chemical uses of manganese oxides; statistics of manganese production of the world for 1913 and 1916.

MINES AND MINING

Accidents

Quarry Accidents in the United States During the Calendar Year 1917, Albert H. Fay. Dept. of the Interior, Bur. of Mines, tech. paper 213, 62 pp. Tables indicating causes of accidents; safety rules promulgated by Nat. Lime Mfrs. Assn.

Africa, South

The Mineral Industry of South Africa and its Future—IV, V & VI. P. A. Wagner. S. A. Min. & Eng. Jl., vol. 28, parts I & II, nos. 1429, 1430 and 1432, Feb. 15, 22 and Mar. 8, 1919, p. 572, 597 and 27. Feb. 15: Iron, kaloin and lead mining. Feb. 22: Zinc, arsenic, magnesite, manganese, mica, soda, talc, tungsten. Mar. 8: Lime, rock phosphate, chert, gypsum, kieselguhr, salt, cement, clay products, and structural material. Presidential address read before S. A. Assn. for the Advancement of Science. (To be continued.)

British Columbia

History of Mining and Metallurgical Development in British Columbia. Min. & Eng. Rec., vol. 24, no. 1, Jan. 1919, pp. 6-11, 9 figs. From the discovery of gold in 1851 to construction of mill at Allenby, B. C.

Cuba

Historical Sketch of the Mining Industry in Oriente, Cuba (Resena historica sobre la mineria en Oriente, Cuba). Boletin de Minas, no. 5, 1918, pp. 26-40. Iron mining on northern coast. (Continued.)

Doors, Separation

Separation Doors at the Bottom of the Upcast Pit, Worked Automaticaly by Tubs Attached to Endless-Rope (Under-Tub) Haulage, Clement Fletcher. Trans. Manchester Geol. & Min. Soc., vol. 36, part 11, Mar. 1919, pp. 31-33, & 4 figs. on plate between p. 64 and cover. Doors work vertically in machined gun-metal grooves and are operated by two Hans Renold roller chains.

Drainage

Tapping and Draining a Deep Shaft, J. Fox. Colliery Guardian, vol. 117, no. 3038, Mar. 21, 1919, pp. 659-660, 3 figs. Sketches showing erosive action of water on borehole.

Drilling and Stripping

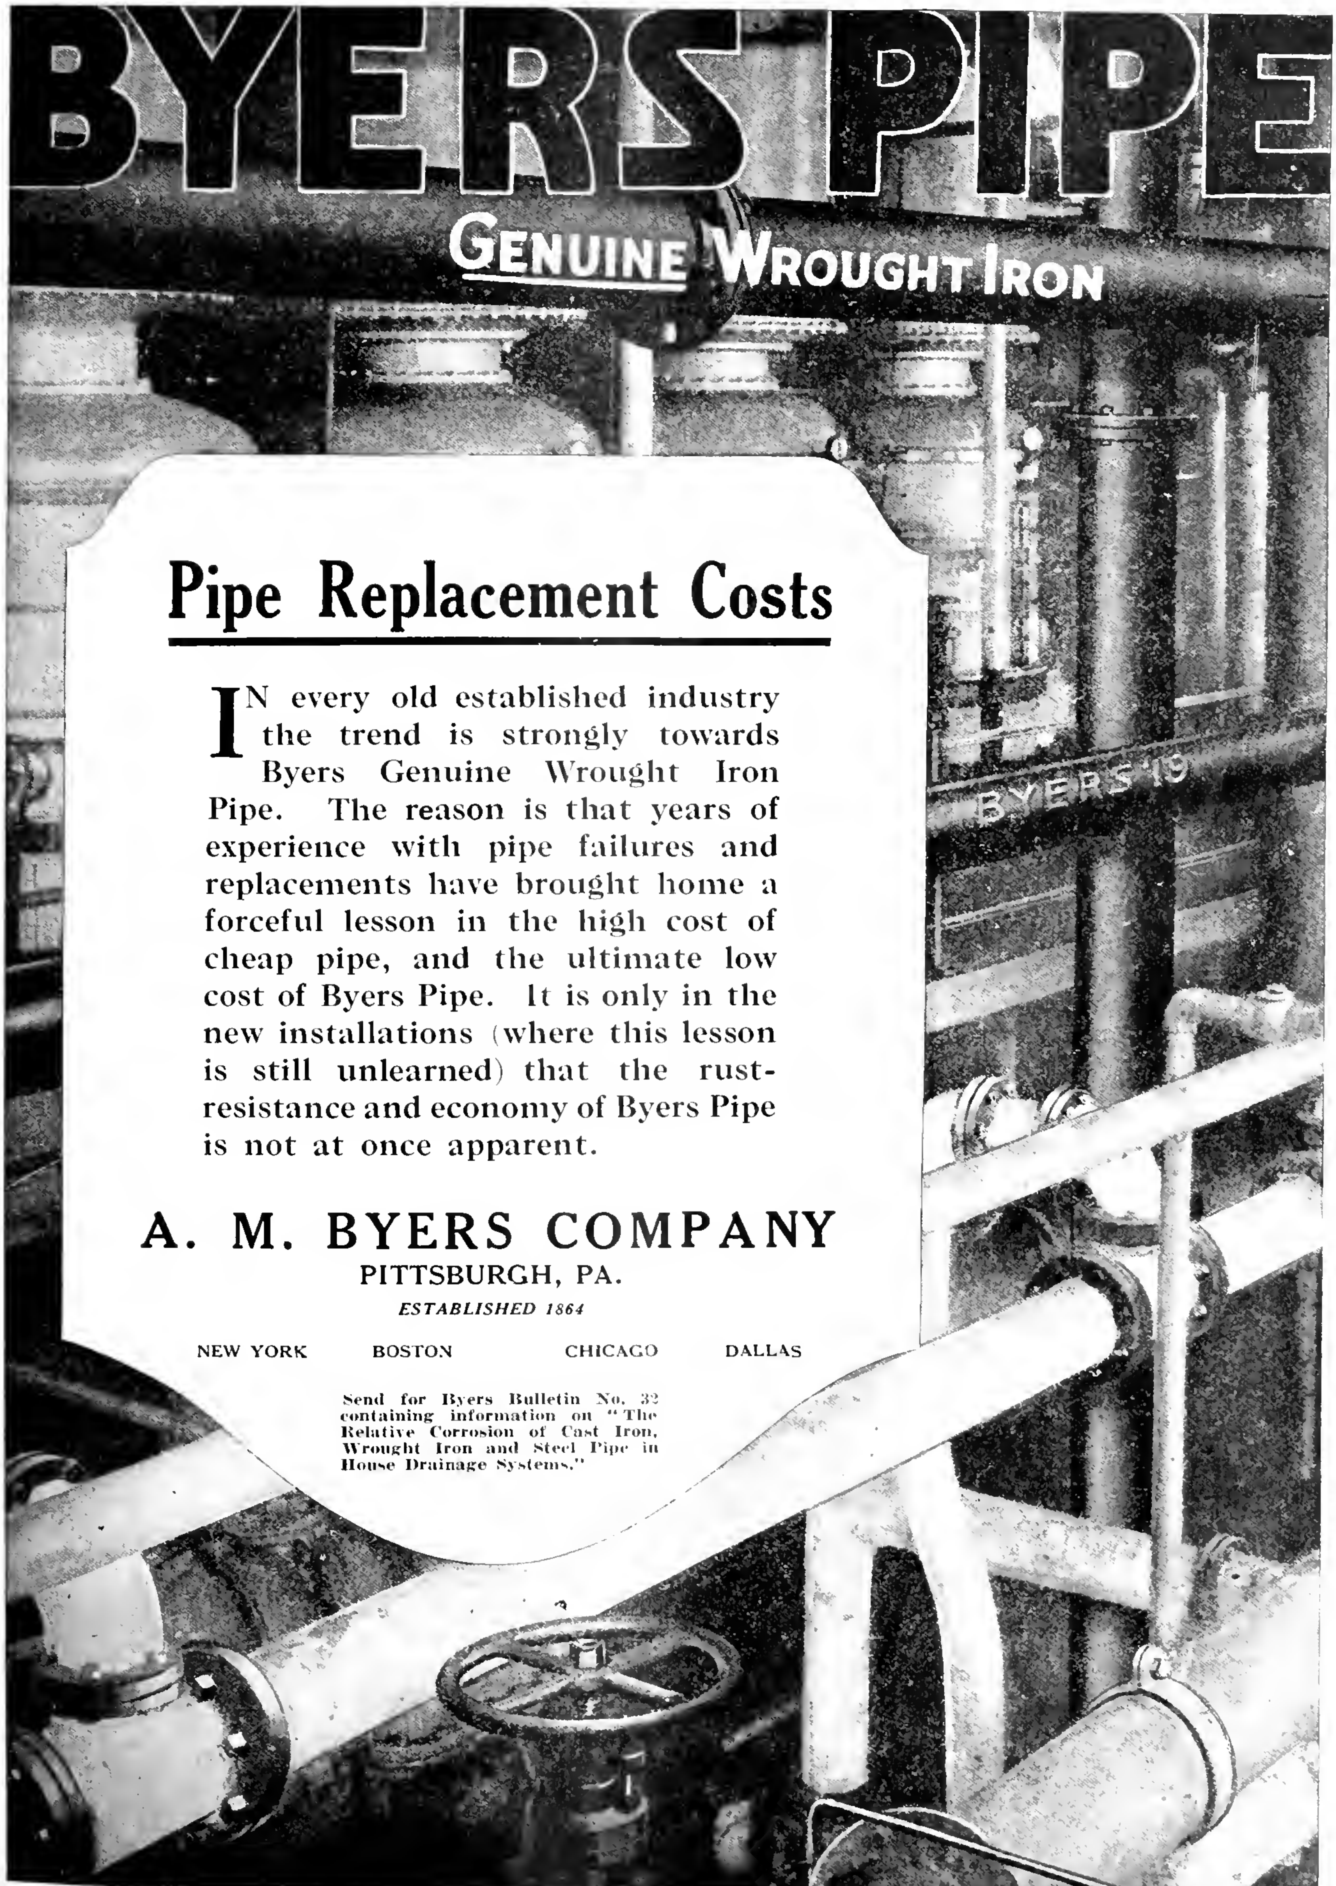
The Blow of the Drill Bit, Sharp or Dull, Frank Richards. Eng. & Min. Jl., vol. 107, no. 17, Apr. 26, 1919, pp. 735-736, 1 fig. Explanation of failure of steel to stand up under action is found in consideration of forces which act and react in drill-striking operation.

Heavy Drilling at Sacramento Hill, Robert T. Banks. Eng. & Min. Jl., vol. 107, no. 16, Apr. 19, 1919, pp. 690-691, 2 figs. Method adopted provides for series of benches which are operated simultaneously, steam shovels being used to load rock into cars after it has been drilled and blasted.

Stripping and Drilling Methods at the Sacramento Hill Copper Mines. Eng. & Contracting, vol. 51, no. 16, Apr. 16, 1919, pp. 389-390, 4 figs. Hill laid off in benches and drilling is effected by Sullivan "Hyspeed" pistol drill with $^3/_4$-in. cylinder diameter.

Hoisting Machinery

Electric Cables at Mines, Iron & Coal Trades Rev., vol. 98, no. 2666, Apr. 4, 1919, pp. 405-407, 5 figs. Regulations proposed by various mining engineers in the light of their experience. Discussion of paper published in Iron & Coal Trades Rev., Feb. 21.



BYERS PIPE
GENUINE WROUGHT IRON
BYERS 19
Pipe Replacement Costs
IN every old established industry the trend is strongly towards Byers Genuine Wrought Iron Pipe. The reason is that years of experience with pipe failures and replacements have brought home a forceful lesson in the high cost of cheap pipe, and the ultimate low cost of Byers Pipe. It is only in the new installations (where this lesson is still unlearned) that the rust-resistance and economy of Byers Pipe is not at once apparent.
A. M. BYERS COMPANY
PITTSBURGH, PA.
ESTABLISHED 1864
NEW YORK BOSTON CHICAGO DALLAS
Send for Byers Bulletin No. 32 containing information on "The Relative Corrosion of Cast Iron, Wrought Iron and Steel Pipe in House Drainage Systems."

Laws

A Uniform Mining Law for North America, T. A. Godson. Can. Min. Inst. Bul., no. 84, Apr. 1919, pp. 399-405. Considers that present mining laws of Canada are not sufficiently adaptable to mining needs.

Revision of Mining Law of April 21, 1810 (Projet de revision de la loi des mines du 21 avril 1810). M. Couriot. Génie Civil, vol. 74, no. 12, Mar. 22, 1919, pp. 228-232. Modifications in regard to duration of concessions and sharing of profits with the state. Comparisons of French mining law with those of other nations.

Ore Handling

Unloading, Crushing, and Screening at the Arthur Mill of the Utah Copper Company, F. G. Janney. Min. & Sci. Press, vol. 118, no. 14, Apr. 5, 1919, pp. 464-470, 8 figs. Ore comes from mine in trains of 40 cars, which descend on 0.4 per cent grade over 150-ton Strait scale, equipped with Streeter-Amet automatic weighing and recording device, on which ore is weighed while train is moving at rate of two miles per hour.

Ore Reserves

Application of the Theory of Probability in the Determination of Ore Reserves, G. A. Watermeyer. Jl. Chem., Metallurgical & Min. Soc. of South Africa, vol. 19, no. 7, Jan. 1919, pp. 97-107 and (discussion) pp. 107-108, 5 figs. Studies whether there is a law governing distribution of values in determination of ore reserves. Object is to ascertain probability of predicting nature of ore penetrating to various depths from points sampled.

Pillar Supports

Pillar Supports in Fortuna Mines of Braden Copper Co., Chile (Método de explotación en las minas Fortuna de la Braden Copper Co. de Chile Dejando columnas de sostenimiento), Charles Hollister. Ingenieria Internacional, vol. 1, no. 1, Apr. 1919, pp. 13-15, 2 figs. Results obtained by application of method used in Arizona of Ray Consolidated Copper Co.

Rand

Rand Mining in 1918, A. Cooper Key. Eng. & Min. Jl., vol. 107, no. 16, Apr. 19, 1919, pp. 702-703, 1 fig. Data showing past and present position of gold-mining industry.

Safety

Mine Officials and the Safety Problem, Edwin C. Curtis. Coal Indus., vol. 2, no. 4, Apr. 1919, pp. 141-142. Advises that an official be judged by good accident record rather than by his record of production.

Safety Lamps

Safety Lamp Gauzes—IV, T. J. Thomas. Colliery Guardian, vol. 117, no. 3039, Mar. 28, 1919, pp. 714-716, 3 figs. Velocities established in explosive mixtures; composition of air rendered extinctive by addition of dioxide and nitrogen; influence of inert gases on properties of firedamp mixtures; results of exposing methane and air mixtures to high temperatures without sparking.

Screening

Estimating Screen Efficiency, W. O. Borcherdt. Eng. & Min. Jl., vol. 107, no. 15, Apr. 12, 1919, pp. 651-653, 2 figs. Diagram of screen analysis on feed, undersize and oversize samples made on hand screen clothed with identical screening medium used on a mill screen.

Statistics

Mineral Statistics of Peru in 1917 (Estadistica Minera del Perú en 1917), Carlos P. Jimenez. Boletin del Cuerpo de Ingenieros de Minas del Peru, no. 95, 326 pp. Production of coal, oil, gold, silver, copper, lead, zinc, mercury, antimony, vanadium, molybdenum, tungsten, bismuth and natural salts.

Stripping

See Drilling and Stripping above.

Timbering

Safe and Efficient Mine Timbering—IV, R. Z. Virgin. Coal Indus., vol. 2, no. 4, Apr. 1919, pp. 138-141, 4 figs. Cribbing, forepoling under soft roof, timbering high places, inclined seams and using round, notched timber.

Ventilation

Mine Ventilation in the Coeur d'Alenes, Robert N. Bell. Eng. & Min. Jl., vol. 107, no. 14, April 5, 1919, pp. 603-604. Problem presented by air circulation at depth.

See also ELECTRICAL ENGINEERING, Power Applications (Mine Service).

MINOR INDUSTRIAL MATERIALS

Barytes

Barytes, Percy A. Wagner. South African Jl. Industries, vol. 2, no. 2, Feb. 1919, pp. 143-146. Mode of occurrence and sources of supply; commercial uses; dressing and preparation; valuation and prices.

Magnesite

Magnesite on the Island of Margarita, Charles F. Z. Caracristi. Eng. & Min. Jl., vol. 107, no. 1, Apr. 12, 1919, pp. 645-647, 1 fig. Geological examination has led writers to believe that there are important magnesite deposits on Venezuelan island.

Mercury

Quicksilver in 1917, F. L. Ransome. Dept. of Interior, U. S. Geol. Survey, Mineral Resources of U. S. A., 1917—Part I, pp. 367-455, Mar. 18, 1919. Statistics of production, including general review of important quicksilver deposits of the world, section on mining of quicksilver ores, and bibliography.

Salpeter

Economics of Chile (Chile Economico), Pedro Luis Gonzalez. Boletin de la Sociedad de Fomento Fabril, vol. 35, no. 12, Dec. 1918, pp. 811-821. Special reference is made to mineralogy, metallurgy and salpeter deposits.

Tungsten

Wolfram Mining in Bolivia, G. F. J. Preumont. Eng. & Min. Jl., vol. 107, no. 14, Apr. 5, 1919, pp. 597-600. Development of industry in recent years. Bolivia is considered by writer as second in importance to Malay States in production.

Cobalt, Molybdenum, Nickel, Titanium, Tungsten, Radium, Uranium, and Vanadium in 1916, Frank L. Hess. Dept. of Interior, U. S. Geol. Survey, Mineral Resources of the U. S. A., 1916—Part I, pp. 775-807, Feb. 25, 1919. Statistics of production, importation and mining conditions.

OIL AND GAS

California

Structure and Oil Resources of the Simi Valley, Southern California, William S. W. Kew. Dept. of Interior, U. S. Geol. Survey, Bul. 691-M, Contributions to economic geology, 1918, part II, Apr. 3, 1919, pp. 323-347. Geology of oil fields.

Drilling

The Percussion System of Drilling Oil Wells, Maurice A. Ockenden and Ashley Carter. Petroleum Times, vol. 1, no. 2, Mar. 22, 1919, pp. 219-222, 2 figs. Plant used in connection therewith. (To be concluded.) Paper read before Instn. Petroleum Technologists.

Gas Testing

Testing Natural Gas for Gasolene Content, G. A. Burrell. Water & Gas Rev., vol. 29, no. 10, Apr. 1919, pp. 12-13, 2 figs. Apparatus which condenses gasoline vapor out of gas and measures yield.

Gas Traps

Traps for Saving Gas at Oil Wells, W. R. Hamilton. Dept. of the Interior, Bur. of Mines, tech. paper 209, petroleum technology 49, 34 pp. 19 figs. Types of traps. Their use is represented as advantageous in increasing gasoline content of gas and eliminating part of storage losses.

Geological Surveying

How a Petroliferous Region is Studied (Come si studia un giacimento petrolifero). Ingegneria Italiana, vol. 3, no. 63, Mar. 13, 1919, pp. 174-177. General examination, geological survey and financial study as preliminary steps before prospecting.

Montana

Anticlines in a Part of the Musselshell Valley, Musselshell, Meagher, and Sweetgrass Counties, Montana, C. F. Bowen. Dept. of Interior, U. S. Geol. Survey, Bul. 691-F, Contributions to economic geology, 1918, part II, Nov. 22, 1918, pp. 185-209, 1 fig. Previous investigators have asserted that there is an area in this region where the rocks have undergone considerable folding. On basis of this information work was conducted to determine measure and extent of folds and to examine possible occurrence of accumulations of oil and gas in them.

Oil and Gas Geology of the Birch Creek-Sun River Area, Northwestern Montana, Eugene Stebinger. Dept. of Interior, U. S. Geol. Survey, Bul. 691-E, Contributions to economic geology, 1918, part II, Aug. 13, 1919, pp. 149-184, 4 figs. Presentation of unquestionable evidence having bearing on oil and gas prospects in specified area, including descriptions of broader features of geology and account of local structural characteristics which have been accounted as possible sources of oil and gas.

Oklahoma

New Development for Oil and Gas in Oklahoma during the past Year and Its Geological Significance, Geo. E. Burton. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 53-59. From data submitted it is believed that the Pennsylvanian shales are much nearer the surface than it has been supposed.

Petroleum Structure

Petroleum Under the Miscroscope. No. 21, Spontaneous Ignition of Oil, James Scott. Petroleum World, vol. 16, no. 222, Mar. 1919, pp. 108-110, 3 figs. Showing formation of pyrites capable of inducing spontaneous ignition, owing to the comparatively large amount of space filled with gas.

Shales

Oil Shales of the Great Uintah Basin, Utah, Don Maguire. Salt Lake Min. Rev., vol. 21, no. 1, Apr. 15, 1919, pp. 21-26, 4 figs. Report of Mineralogical Survey. From Mineralogist & Metallurgist.

Storage

The Fireproof Storage of Petrol. Petroleum World, vol. 16, no. 222, Mar. 1919, pp. 128-132, 3 figs. Description of Martini and Hüneke pressure-type pumping plant. (To be continued.)

Texas

Natural Gas Resources of Parts of North Texas. Dept. of Interior, U. S. Geol. Survey, Bul. 629, 1916, 129 pp., 20 figs. Estimates of gas remaining in development pool.

Water

Water in Oil and Gas Wells, F. B. Tough, Petroleum Times, vol. 1, no. 2, Mar. 22, 1919, pp. 229-231. Formulæ for computing probable collapsing pressure for commercial sizes of casing.

PRECIOUS MINERALS

Arizona

Gold, Silver, Copper, Lead, and Zinc in Arizona in 1917, V. C. Heikes. Dept. of Interior, U. S. Geol. Survey, Mines Report, Mineral Resources of U. S. A., 1917—Part I, pp. 509-548, Apr. 1, 1919. Figures of output in marketable form as obtained from smelters, refineries and mints; review of industries of entire country; production in terms of recoverable metal in ores and other material sold or treated during calendar year. Information relative to mining industry in respective states, counties and mining districts.

Colombia

The Guamoco District of the Republic of Colombia—II, S. Ford Eaton. Eng. & Min. Jl., vol. 107, no. 14, Apr. 5, 1919, pp. 609-613, 2 figs. Peculiar transportation difficulties in gold mines.

Idaho and Washington

Gold, Silver, Copper, Lead and Zinc in Idaho and Washington in 1917, C. N. Gerry. Dept. of Interior, U. S. Geol. Survey, Mineral Resources of the U. S. A., 1917, part I, pp. 457-507, Apr. 3, 1919. Statistics of production.

Ontario

The Gold-Quartz Lodes of Porcupine, Ontario, Ellsworth Y. Dougherty. Min. & Sci. Press, vol. 118, no. 16, Apr. 19, 1919, pp. 532-536, 8 figs. Occurrence of tourmaline and feldspar with coarsely crystalline and fluid-enclosing ore-quartz led to classification of orebodies as high-temperature deposits, formed under great depth and pressure through the agency of igneous activity.

Platinum

An Investigation of Certain Canadian Platinum and Manganese Resources, G. C. Mackenzie. Can. Min. Inst. Bul., no. 84, Apr. 1919, pp. 425-434. Recovery from refining of Sudbury copper-nickel matte; report of examination of platinum occurrences in Alberta, British Columbia, undertaken by Canadian Munition Resources Commission.

Washington

Men YOU Know are Boosters for Turbo-Gear

Engineers, power transmission experts, plant operators and owners of the leading industries—men you know or know about—are turning more and more to "Turbo-Gear" as the one practical, economical power transformer.

For "Turbo-Gear", low in first cost, free from up-keep expense, economically abolishes the big item of repairing and replacing power transmission equipment.

Cheaper first—and in the end

"Turbo-Gear" is moderate in price in comparison with other power transmission costs—and first cost is the only cost.

The Use of "Turbo-Gear" Means:

1. Greater over-all efficiency
2. Greater safety
3. Continuous operation
4. Positive transmission of power—no slip
5. Less floor space used therefore lower overhead

By the way of pointing out what "Turbo-Gear" can do for you let us tell you what it is doing for others.

Begin today by sending for Bulletin No. 101.

Metallurgy

ALUMINUM

Micrography

The Micrography of Aluminum and its Alloys, D. Hanson and S. L. Archbutt. Engineering, vol. 107, no. 2779, Apr. 4, 1919, pp. 450-453, 13 figs. Different microstructural constituents met with in aluminum alloys, and methods by which these may be etched for microscopic examination. Paper read before Inst. of Metals.

Metallography

The Metallography of Aluminum—I & II, Robert J. Anderson. Metal Industry, vol. 14, nos. 12 & 13, Mar. 21 & 28, 1919, pp. 223-228 and 245-247, 20 figs. Discussion of amorphous theory and plastic deformation witb remarks on grain growth phenomena; microstructure of various forms of aluminum; annealing and recrystallization of aluminum which has had plastic deformation; polishing and etching of aluminum microsections preparatory to microscopic examination.

COPPER AND NICKEL

Nickel Refining

Some Features of Nickel Refinery. Can. Manufacturer, vol. 39, no. 4, Apr. 1919, pp. 21-24, 8 figs. Features of Int. Nickel Co. of Canada refinery. Plant was erected at cost of \$5,000,000.

FERROUS ALLOYS

Chromium-Nickel Steel

Critical Points, L. A. Danse. Proc. Steel Treating Research Soc., vol. 2, no. 3, 1919, pp. 32-38. Discussion of mechanical and thermal treatment of chromium-nickel steel, particularly as used in aircraft production.

FLOTATION

Flotation Experiments

A Device for Flotation Experiments, Will H. Coghill. Min. & Sci. Press, vol. 118, no. 15, Apr. 12, 1919, pp. 495-496, 1 fig. Device consists of two pyrex flasks, one of 250 cc. and the other of 500 cc., fitting in same rubber nipple; to prepare a test, smaller flask is filled with mixture of ore and water of desired consistency and emptied into larger one; flotation reagents are added and test is accomplished by hand agitation.

FURNACES

Air-Volume Regulation

Air-Volume Regulation in Smelting and Refining Furnaces, C. H. Smoot. Eng. & Min. Jl., vol. 107, no. 15, Apr. 12, 1919, pp. 654-656, 3 figs. Type of constant-volume regulator developed by Ratean Rattn-Smoot Eng. Corp.

Gas Heating

Heating of Metallurgical Furnaces (Le chauffage des fours métallurgiques), Louis Lecocq. Chimie & Industrie, vol. 2, no. 3, Mar. 1, 1919, pp. 260-270. Figures indicating advantage of utilizing gas from coke furnaces.

Greene Arc Furnace

The Greene Rolling Cylinder Arc Furnace. Iron Age, vol. 103, no. 16, April 17, 1919, pp. 1005-1007, 3 figs. Principal features are tilting arrangement by use of hydraulic cylinder connected to back of furnace shell, and removable roof.

Pulverized Coal

Pulverized Coal in Canadian Steel Plant, C. F. Herington. Iron Age, vol. 103, no. 17, Apr. 24, 1919, pp. 1065-1069, 7 figs. Air distributing system supplies powdered fuel for boilers and furnaces at Canadian branch of Armstrong Whitworth Co.

See also MECHANICAL ENGINEERING, *Furnaces*; ELECTRICAL ENGINEERING, *Furnaces*.

IRON AND STEEL

Gray Iron

Improving the Quality of Gray Iron by the Electric Furnace, George K. Elliott. General Meeting Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 11, pp. 173-179. Proposes to use a basic-lined arc electric furnace for refining and superheating gray iron. Cupola is said to be strong on heating and melting, but weak in superheating, carbon regulation, waste of alloying metals, and impossibility of refining; consequently, duplex process, using electric furnace in tandem with cupola, is believed will correct and supplement deficiencies of cupola.

Hot Deformation

Hot Deformation and the Quality of Steel, Georges Charpy. Iron Age, vol. 103, no. 17, Apr. 24, 1919, pp. 1079-1081, 3 figs. Experiments determining effect on tensile strength and impact values; gun and hard basic steel were used. Paper presented before Iron & Steel Inst., London.

Liquid Steel

Paper on "The Solid and Liquid States of Steel," Cosmo Johns. Jl. West of Scotland Iron & Steel Inst., vol. 26, part 3, 1918-1919, pp. 36-41. Properties of an optically clean surface of liquid steel and its similarity to that of a polished metallic surface with a vitreous film. Preservation of surface of liquid steel is attributed to presence of iron-vapor atmosphere.

Malleable Iron

Malleable Iron, What it is, and How it is Made, F. H. Bell. Can. Foundryman, vol. 10, no. 4, Apr. 1919, pp. 85-88, 7 figs. Organization in operation of foundry works.

Manganese

Manganese Alloys in Open-Hearth Steel Practice, Samuel L. Hoyt. Sci. Am. Supp., vol. 87, no. 2261, May 3, 1919, pp. 282-283. Conditions in open-hearth practice that affect conservation of manganese, both during the working of the heat and in making final additions; metallurgical conditions for use of manganese in the form of low-grade or special alloys; effect on finished steel both as to quality and condition of various methods and processes.

Ore Smelting

A New Method for the Smelting of Iron Ores, J. W. Moffat. Can. Machy., vol. 21, no. 14, Apr. 3, 1919, pp. 325-327. Duplex process for making of steel from ores not suitable for blast furnace.

Phosphorus in Steel

The Determination of Phosphorus in Vanadium Steels, Ferro-Vanadium, Non-Vanadium Steels and Pig Iron, Chas. Morris Johnson. Chemical News, vol. 118, no. 3073, Mar. 7, 1919, pp. 113-115. Method for steel containing vanadium up to 2.6 per cent; table showing effect of increasing amounts of nitric acid on phosphorus recovery.

See Mechanical Processes (Steel Mills), under MECHANICAL ENGINEERING.

Tempering Velocity, Critical

Influence of Various Factors on the Critical Velocity of Tempering of the Carbon Steels (Influence de divers facteurs sur la vitesse critique de tremps des aciers au carbone), I. M. Portevin. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 7, Feb. 17, 1919, pp. 346-348. Duration of temper was determined in the experimental work as the time in seconds for cooling of metal from 700 to 200 deg. cent.

Toronto Electric Steel Plant

World's Largest Electric Steel Plant in Toronto, George T. Clark and Frederick Phillips. Can. Engr., vol. 36, no. 13, Mar. 27, 1919, pp. 327-331, 10 figs. Plant occupies 127.65 acres, and 5000 lin. ft. of concrete docks, accommodating vessels of 24 ft. draft. It was built for manufacture of 6-in. and 9.2 in. forgings from raw material.

NON-FERROUS ALLOYS

Aluminum Alloys

Alloys of Aluminum with Rare or Special Alloys, Jean Escard. Metal Industry, vol. 13, no. 20, Nov. 15, 1918, pp. 333-335. Constitution, properties and preparation of aluminum and manganese, aluminum and chromium, aluminum and tungsten, aluminum and vanadium, and aluminum and titanium alloys.

Aluminum Bronzes

Study and Graphical Representation of the Properties of Aluminum Bronzes (L'étude et la représentation graphique des propriétés des bronzes d'aluminum), R. de Fleury. Génie Civil, vol 74, no. 13, Mar. 29, 1919, pp. 254-256, 9 figs. Triangular diagrams of resistance to rupture and ultimate elongation of bars.

Brass

Notes on Alloys Used in Brass Rolling Mills, A. J. Franklin. Metal Industry, vol. 14, no. 12, Mar. 28, 1919, pp. 241-244, 3 figs. Effect of impurities, casting difficulties, hints on annealing and composition of some of the alloys used in sheet-rolling mill.

Decomposition

Decomposition of Metals—II, A. I. Krynitzky. Chem. & Metallurgical Eng. vol. 20, no. 8, Apr. 15, 1919, pp. 421-424, 6 figs. Application of theory to commercial problem of manufacturing durable alloys containing tin and aluminum, with outline of recommended melting, drawing and annealing practice for certain munitions.

Metallography

Metallography Applied to Nonferrous Metals—II, Ernest J. Davis. Foundry, vol. 47, no. 5, Apr. 15, 1919, pp. 215-218, 15 figs. Predicting microstructure of series of alloys by equilibrium diagram.

OCCLUDED GASES

Occlusion

Occlusion of Gases by Metals (L'occlusion des gaz par les métaux), A. Delesne. Revue Générale des Sciences, vol. 30, no. 1, Jan. 15, 1919, pp. 17-19. Synopsis of discussion at conference of Faraday Soc., London.

VARIA

Etching Solutions

Etching Solutions and their Uses, Ernest G. Jarvis and McNab and Harlin Mfg. Co. Metal Indus., vol. 17, no. 4, Apr. 1919, pp. 170-171. Preparation and uses of seventeen different solutions.

Manganese-Silver Problem

The Manganese-Silver Problem—I, Harry J. Wolf. Colorado School of Mines Mag., vol. 9, no. 4, Apr. 1919, pp. 73-77. Metallurgical experiments performed to determine reason for insolubility in cyanide of silver in certain ores where it is accompanied by manganese oxides.

Aeronautics

AIRCRAFT

Airship Developments

The Case for the Airship, Ladislas d'Orcy. Jl. So. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 303-307, 10 figs. Progress made since 1914.

The Development of Airship Construction, C. I. R. Campbell. Engineering, vol. 107, no. 2780, Apr. 11, 1919, pp. 469-472, 3 figs. General particulars of non-rigid, semi-rigid and rigid airships. Paper read before Insta. Naval Architects.

Ballooning

Free Ballooning, a Notable Factor in the Royal Air Force, Lance Rushbrooke. Flight, vol. 11, no. 13, Mar. 27, 1919, pp. 394-396, 7 figs. Use of free balloons in reconnaissance, transmission of messages, photography and other military purposes.

Commercial Use

The Commercial Use of Airships. Nature, vol. 103, no. 2575, Mar. 6, 1919, pp. 4-5. Discusses possibilities of use of airships in immediate future, and compares between large airplane and rigid airship.

Design

Lighter-than-Air Craft, T. R. Cave-Browne-Cave. Flight, vol. 11, no. 13, Mar. 27, 1919, pp. 410-416, 1 fig. Matters which influence lift and behavior of airship. Paper read before Roy. Aeronautical Soc.

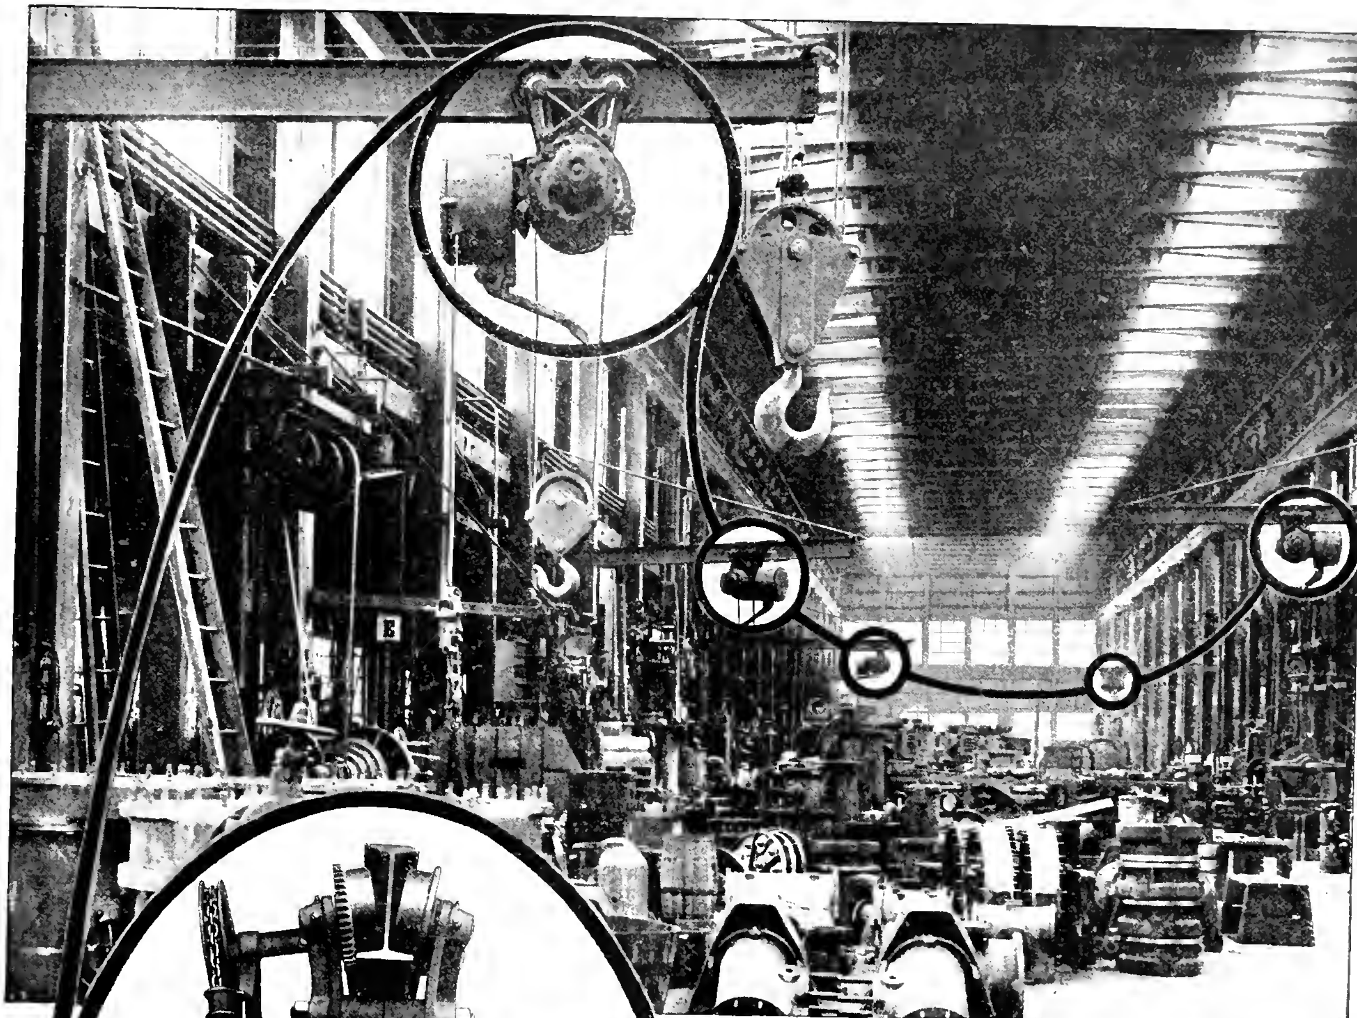
Aerial Greyhounds of To-Morrow. Sci. Am. vol. 120, no. 16, Apr. 19, 1919, pp. 400-401 and 418, 3 figs. Constructural features of air ships for future transatlantic service.

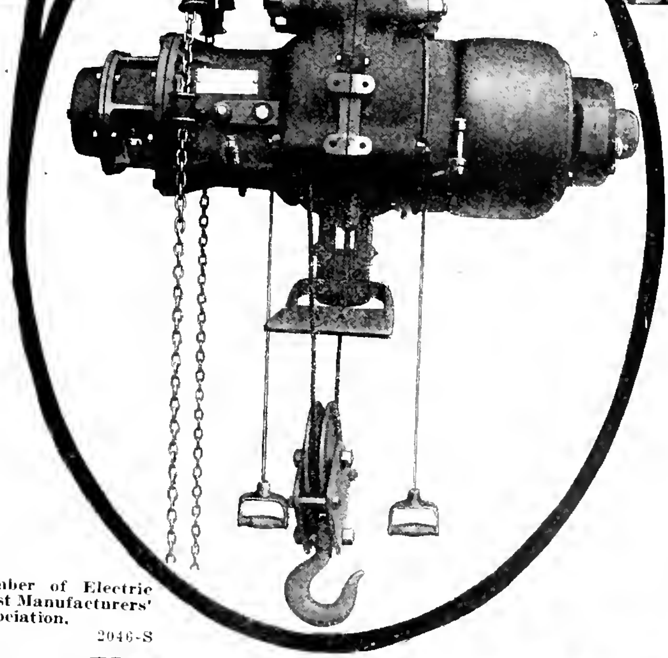
Helium

The Use of Helium for Aircraft Purposes Nature, vol. 102, no. 2573, Feb. 20, 1919, pp 487-488. On increasing buoyancy of airshi by heating gas electrically or otherwise.

Transport Service

The Possibilities of Airship Transport Service. Flight, vol. 11, no. 8, Feb. 20, 1919, pp 230-232, 1 fig. Estimated cost of running Atlantic airship service, London-New York financial and working arrangements and Government subsidy; general specifications of proposed airship for transport service. (Continuation of serial.)





"Shepards"— all over the shop

Where you find Shepard Hoists there you find work is carried on with the highest degree of efficiency, for each "Shepard" represents a saving in time and labor—one man can operate a "Shepard" and handle a piece it would take a gang to lift, and in half the time.

Give a "Shepard" consistent, steady, "day in, day out" work—it's sturdy and built for that kind of service.

It's unaffected by dirt, dust or dampness—because all electrical and mechanical parts are protected by the "closed in" unit construction.

The Shepard Line includes electric traveling cranes, monorail cranes and hoists, with either plain or motor operated trolleys, ½ to 30 tons. Our engineers will be glad to serve you.

Shepard Electric Crane & Hoist Co.

370 Schuyler Avenue, Montour Falls, N. Y.

New York, Philadelphia, Chicago, Pittsburgh, Boston, Baltimore, Cleveland, San Francisco, Montreal, Melbourne, London.

Member of Electric Hoist Manufacturers' Association.

REG. U.S. PAT.OFF.

SHEPARD

ELECTRIC CRANES & HOISTS

APPLICATIONS

Buenos Aires-Pernambuco Service

The Buenos Aires-Pernambuco Aerial Service (El servicio aero Buenos Aires-Pernambuco). La Ingenieria, vol. 23, no. 6, Mar. 16, 1919, pp. 389-398, 5 figs. Project contemplates making total distance of 2700 miles in 38¼ hr. actual flying time. Handley Page, Rolls-Royce and Sunbeam machines will be used.

Landings, Marking

The Future of the Airplanes in Business, C. B. Merrick. Jl. Electricity, vol. 42, no. 7, pp. 309-310, 3 figs. Marking landing places and guide posts by electricity.

Regulations

Regulations for Air Navigation. Automotive Industries, vol. 40, no. 15, Apr. 10, 1919, pp. 782-785. Project of Int. Convention regarding air navigation.

DESIGN

Landing

Commercial Feature of Airplanes from an Engineer's Standpoint, G. H. Day. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 290-292. Sees as most important development of future that which will enable aeroplanes to land in small field, this to be obtained without too great a sacrifice of high speed.

Types, Characteristics

Airplane and Seaplane Engineering, H. C. Richardson. Jl. Soc. Automotive Engrs., vol. 4, no. 4, Apr. 1919, pp. 273-285, 12 figs. Characteristics of types devolved and discussion of factors affecting their performance.

DYNAMICS

Curvilinear Flight

The Aeroplane in Curvilinear Flight. Aeronautical Jl., vol. 23, no. 97, Jan. 1919, pp. 23-24. Expressions for determining approximately the relation between B and other quantities. From Schweiz. Aero Club Bul. nos. 8 and 9.

Stresses in Landing Gear

A Theoretical Investigation into the Stresses Arising in the Landing Gear of an Aeroplane, H. B. Thomas. Flight, vol. 11, no. 15, Apr. 10, 1919, pp. 483-484. In relation to probability of machine landing automatically.

Tests on Models

From Model to Full Scale in Aeronautics, H. Levy. Aeronautics, vol. 16, no. 284, Mar. 27, 1919, pp. 348-352. Technical analysis of following problem: Flying machine or part of one is in motion through the air with a given speed in the region of normal speed of flight; is there a corresponding experiment on a model from which the forces originated on the full scale may be deduced?

ENGINES

A. B. C.

The British A. B. C. Aero Engines. Aerial Age, vol. 9, no. 7, Apr. 28, 1919, p. 335, 4 figs. Outstanding feature of these models is copper coating on cooling fins.

Basse-Selve

The 270 H. P. Basse-Selve Aero-Engine. Engineer, vol. 127, no. 3298, Mar. 14, 1919, pp. 246-248, 11 figs. also Aerial Age, vol. 9, no. 5, Apr. 14, 1919, pp. 247-248, 253-255 and 262, 26 figs. Report on design based on examination of engine taken from remains of a German Rumpler two-seater biplane shot down and destroyed in France on May 31, 1918.

British

Current Types of British Aero Engines. Aeronautics, vol. 16, no. 284, Mar. 27, 1919, pp. 329-342, 20 figs. Siddeley-Deasy, (Puma) Napier Lion, Mercury, Lucifer, Hercules, Jupiter, Gnat I, Dragon Fly, "Manitou" Sunbeam-Coatalen, Maori IV, B.R.1 and B.R.2 types.

Crankshafts

The Design of Aeroplane Engines—XXI, John Wallace. Aeronautics, vol. 16, no. 282, Mar. 12, 1919, pp. 272-276, 7 figs. Points on crankshaft design; polar curve of crankpin load.

Dusenberg

The World's Largest Airplane Engine. Gas Engine, vol. 21, no. 5, May 1919, pp. 162-164, 10 figs. Dusenberg 850-hp. 1575-lb. engine.

Hall-Scott

Hall-Scott Type L-6a Aero Engine. Aerial Age, vol. 9, no. 7, Apr. 28, 1919, pp. 346-347, 5 figs. Characteristics of six-cylinder, 495-lb., 200-hp. engine.

King-Bugatti

King-Bugatti 16-Cylinder Aero Engine. Automotive Industries, vol. 40, no. 17, Apr. 24, 1919, pp. 906-910, 7 figs. Consists of two 8-cyl. all-in-line engines, mounted on common crankcase and geared to common propeller shaft. Designed to permit 37-mm. cannon to shoot through hollow propeller shaft. (To be continued.)

Mercedes

200 H.P. Compression Mercedes Engine. Flight, vol. 11, no. 8, Feb. 20, 1919, pp. 233-236, 9 figs. Report on running performance. Issued by Technical Dept. (Aircraft Production) Ministry of Munitions.

Napier Lion

The Napier Lion Aeromotor. Flight, vol. 11, no. 13, Mar. 27, 1919, pp. 397-402, 12 figs. Twelve-cylinder 450 hp. engine with record of 30,500-ft. altitude.

Siddeley

The Siddeley Aero Engines—"Puma" and "Tiger." Flight, vol. 11, no. 14, Apr. 3, 1919, pp. 429-433, 4 figs. Puma engine has 6 vertical cylinders, 145 mm. bore by 190 mm. stroke; valves are in cylinder heads and are worked by overhead camshaft. Tiger engine has two lines of 6 cylinders inclined at an angle of 60 deg.; valves are worked by two overhead camshafts. These engines were intended for use in areoplanes making long-distance journeys into Germany.

Supercharging

Maintaining Constant Pressure Before the Carburetors of Aero Engines Regardless of the Altitude, Leslie V. Spencer. Aerial Age, vol. 9, nos. 5 and 7, Apr. 14 and 28, 1919, pp. 244-246 and 264, and pp. 336-337 and 356, 10 figs. Arrangement of Sherbondy turbo-compression as laid out for Liberty 12-cyl. engine. (To be continued.)

MODELS

Slotted Armature

Localization of the Transformation of Energy in a Slotted Armature (Localización de la transformación de la energía en un inducido dentado), Konrad Simons. Boletin de la Asociación Argentina de Electro Técnicos, vol. 4, no. 11, Nov. 1918, pp. 874-876, 1 fig. Model to demonstrate that forces of magnetic field actuate more on teeth than on conductors.

Motors

Elementary Aeronautics and Model Notes, John F. McMahon. Aerial Age, vol. 9, no. 4, Apr. 7, 1919, p. 213. Motorcycle driven aeroplane.

Elementary Aeronautics and Model Notes, John F. McMahon. Aerial Age, vol. 9, no. 5, Apr. 14, 1919, p. 259, 2 figs. Ford motor rebuilt for aeroplane work.

PLANES

Armstrong-Whitworth

The Armstrong-Whitworth Machines. Flight, vol. 11, no. 14, Apr. 3, 1919, pp. 438, 21 figs. History, development and characteristics of the various types.

Caproni

The Caproni E-3 Night Bomber. Aviation, vol. 6, no. 6, Apr. 15, 1919, pp. 322-325, 3 figs. Outline drawings.

The Caproni Triplane. Aerial Age, vol. 9, no. 5, Apr. 14, 1919, pp. 242-243, 5 figs. Specifications of type CA-4 triple-motored Caproni triplane.

Georges Levy

The Georges Levy Type R Flying Boat. Aerial Age, vol. 9, no. 6, Apr. 21, 1919, pp. 286-288, 3 figs. Directions for rigging and mounting as applied by Georges Levy Co.

Grahame-White

An Interesting Grahame-White Sporting model. Flight, vol. 11, no. 15, Apr. 10, 1919, pp. 468-473, 19 figs. Span is only 20 ft. and overall length 16 ft. 6 in. Machine, however, is said to be capable of making 102 m.p.h. at low altitudes and 93 m.p.h. at 10,000 ft. It is fitted with 80-hp. le Rhone engine.

Navy

F-5-L Navy Flying Boat—IV, S. T. Williams. Automotive Industries, vol. 40, no. 15, Apr. 10, 1919, pp. 809-811, 2 figs. Flying controls and methods of hook-up; weight and percentage of weight of every component.

The Navy HS-1L and 2L Flying Boats. Aerial Age, vol. 9, no. 7, Apr. 28, 1919, pp. 338-340 and 357, 6 figs. General dimensions and data.

TESTING

Sand Testing

Sand Testing of Aeroplanes, Albert S. Heinrich. Aerial Age, vol. 9, no. 4, Apr. 7, 1919, pp. 200-202, 10 figs. Test of tail surfaces. (Continued.)

TRANSATLANTIC FLIGHT

British Machines

The Transatlantic Race. Flight, vol. 11, no. 15, Apr. 10, 1919, pp. 476-480, 5 figs. British machines intended to be used for the projected flight.

Marine Engineering

AUXILIARY MACHINERY

Compasses

The Gyroscopic Compass. Pac. Mar. Rev., vol. 16, no. 4, Apr. 1919, pp. 105-106, 1 fig. Sperry gyroscopic compass equipment for merchant vessels.

SHIPS

Concrete Ships

Economic Size of Concrete Ships, E. O. Williams. Eng. & Contracting, vol. 51, no. 18, Apr. 30, 1919, pp. 463-465, 1 fig. Curves showing various comparisons between concrete ships and steel.

Diesel Engine

Diesel Engine or Steam Engine. Shipbuilding & Shipping Rec., vol. 13, no. 13, Mar. 27, 1919, pp. 381-382. Discussion of relative economies in marine-engine practice.

Electric Propulsion

Electric Propulsion as Developed on Battleship New Mexico. Elec. Rev., vol. 74, no. 15, Apr. 12, 1919, pp. 579-584, 6 figs. Electrical features of propelling equipment, specially the two turbine-generators and four induction motors direct-connected to propellers.

Electrical Propulsion of Ships, J. F. Nielson. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 432-437. Electrical transmission gears compared with mechanical gears. Emphasis is laid upon greater immunity from total breakdown possessed by electrical method, due to possibility of utilizing a plurality of motor and generator units.

Electric Drive of the U. S. S. New Mexico. Elec. World, vol. 73, no. 16, Apr. 19, 1919, pp. 780-783, 5 figs. Machinery is divided into two parts and ship is said to be able to make 17 knots with half of machinery disabled.

Electrical Equipment

Generating Machinery for Merchant Ships, F. P. Fenton. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 451-453, 4 figs. Considered in various aspects, such as pressure of supply and type of current, character of primer mover and generator, type of coupling, position of plant in the ship and requirements of various classes of vessels.

Electric Light and Power Circuits on Board Ship, O. H. Kennedy. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 438-443, 8 figs. Diagrams showing system and methods of control.

Propellers

Experimental Research of the Turning Action of a Propeller in a Ship (Richerche sperimentali interno all azione evolutiva esercitata dalle eliche). N. Pecoraro. Revista Maritima, vol. 52, no. 2, Feb. 1919, pp. 175-192, 3 figs. Formula for angle to which rudder has to be inclined in order for the ship to maintain a straight course when only one propeller is operated; experimental confirmation of theoretical results.

Graphic Solution of Propeller Formulae, J. S. Redshaw. Shipbuilding & Shipping Rec., vol. 13, no. 15, Apr. 10, 1919, pp. 436-437, 2 figs. Charts for determining diameters for three-bladed propellers by solution of Taylor's formula and Taylor's ρ value.

"Certified"

Every foot of Plastic-Arc Certified Welding Metal (patented) carries our guarantee that it can be depended upon to do exactly what it was made for and that it is uniformed throughout

These certified metals give maximum results when used with a welder employing low voltage and a constant, automatically regulated current, the fundamentals of Plastic-Arc Welding. They will, however, give more satisfactory results with any system of welding that can be obtained with ordinary welding metals.

There are eight grades of Plastic-Arc Certified Welding Metals, and each grade has been carefully developed to give maximum results in a definite line of work, as follows:

GRADE NO. 6

For work where ductility and high tensile strength is required.

GRADE NO. 8

Useful for building up worn places where high tensile strength is not required. Can be **readily machined.**

GRADE NO. 9

For use on all cast steel parts requiring high strength in the weld. Standard with many railroads and shipyards for this purpose.

GRADE NO. 17

For use in filling in blowholes in steel and gray iron castings and all work where parts are not subject to undue strains or where tensile strength is not an important factor.

GRADE NO. 20

Bronze alloy for bells and all brass, copper and bronze work.

GRADE NO. 30

This is an exceptionally easy and fast flowing electrode and lays relatively flat where deposited; of medium tensile strength; specially designed for welding thin cast iron.

GRADE NO. 31

High tensile strength and conductivity combined with very smooth flowing specially designed for overhead welding with deep penetration.

GRADE NO. 33

Exceptionally smooth flowing qualities. Specially designed for overhead welding, deep penetration.

Prices and samples of any grade will be furnished upon request

WILSON WELDER AND METALS CO., INC.

2 Rector Street, New York

Smokebox Locks

"Sturdun" Patent Smokebox Locks. Steamship, vol. 30, no. 358, Apr. 1919, pp. 234-235. 2 figs. Invention devised for locking smokebox door.

Standardized Ships

The "Standardized" Ship Schenectady. Am. Mar. Engr., vol. 14, no. 4, Apr. 1919, pp. 5-7, 3 figs. Vessel is designed for deadweight capacity of 7500 tons, total displacement loaded being estimated at 11,200 tons.

Typical U. S. Turbine Driven Carrier. Shipping, vol. 7, no. 4, Apr. 26, 1919, pp. 15-16 and 18, 4 figs. Mechanical equipment of geared-turbine-driven ship "Schenectady."

TERMINALS

Canadian Terminals

The Canadian Government's Ocean Terminals. Mar. Eng. of Canada, vol. 9, no. 3, Mar. 1919, pp. 112-114, 4 figs. Progress on project involving expenditure of $30,000,000.

Charleston

See Wood Construction below.

Coaling

Coaling Ships Mechanically—1, Wilbur M. Stone. Coal Trade Jl., vol. 50, no. 18, Apr. 30, 1919, pp. 479-483, 5 figs. Michener coaling ap-1919, pp. 110 111. Description of harbor and paratus. Elevator automatically frees itself in case of overload without interrupting operations.

Electrical Equipment

Electrical Service at Great Seaboard Terminal. Elec. World, vol. 73, no. 16, Apr. 19, 1919, pp. 784-787, 4 figs. Electrical agencies include elevators, cranes and industrial tractors and trailers.

Elevators

Concrete Shipside Elevator and Warehouse. Concrete Age, vol. 29, no. 6, Mar. 1919, pp. 10-11, 3 figs. Dimensions and operating equipment.

Mechanical Equipment

The Port of Seattle, G. F. Nicholson. Eng. World, vol. 14, no. 8, Apr. 15, 1919, pp. 11-14, 3 figs. Mechanical equipment for handling miscellaneous freight.

New Orleans

New Orleans Army Base Improves Facilities of the Port, George H. Davis. Eng. News-Rec., vol. 82, no. 17, Apr. 24, 1919, pp. 823-826, 5 figs. Three concrete warehouses tied to 2000-ft. wharfhouse on river by bridges permitting access to all floors.

St. John, N. B.

Wooden Shipbuilding Activities at St. John, N. B. Mar. Eng. of Canada, vol. 9, no. 3, Mar. 1919, pp. 110-111. Description of harbor and port.

San Francisco

Port Facilities and Freight Handling. Jl. Electricity, vol. 42, no. 7, Apr. 1, 1919, pp. 294-297, 5 figs. Plans for the improvement of San Francisco Harbor through the adoption of mechanical freight-handling devices.

Seattle

See Mechanical Equipment above.

Wood Construction

Wood Construction Feature of Charleston Port Terminal, Hunley Abbott. Eng. News-Rec., vol. 82, no. 15, Apr 10, 1919, pp. 702-706, 6 figs. Particulars of quartermaster depot for storage and shipment of materials.

See also MECHANICAL ENGINEERING, Handling of Materials (Ship Loading).

YARDS

Castings

Castings Used in Ship Construction, Ben Shaw and James Edgar. Foundry Trade Jl., vol. 21, no. 207, Mar. 1919, pp. 151-156, 17 figs. Preparation of molds for stem pieces.

Concrete Car Floats

Hudson River Shipyard Layout to Build Concrete Car Floats, H. W. Eldridge. Eng News-Rec., vol. 82, no. 15, Apr. 10, 1919, pp. 732-734, 5 figs. Concrete placed for 1600-ton vessels from stiff leg chute tower.

Cranes

Modern Shipyard Cranes, Claude M. Toplis. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 408-412, 4 figs. Comparison of crane systems; double cantilever crane running on high gantry, overhead bridge traveling crane, jib crane running on high gantry and tower crane system.

Davey Plant at Lauzon, Can.

The Davey Shipbuilding Plant at Lauzon. Mar. Eng. of Canada, vol. 9, no. 3, Mar. 1919, pp. 105-107, 6 figs. Installation for building wooden steamers, steel trawlers and large steel steamers.

Electrical Equipment

Electrical Equipment of a Modern Shipyard, A. Henderson. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 400-407, 14 figs. Central station containing four 450-kw. Westinghouse rotary converters, which convert the 3300-volt, 3-phase, 50-cycle supply to 240 volts continuous current for disribution throughout works.

Ford Method

Ford Methods in Ship Manufacture—V, Fred E. Rogers. Indus. Management, vol. 57, no. 5, May 1919, pp. 367-372, 12 figs. Electric rivet heating and welding, flame cutting and boring propeller-shaft bearings.

Ford Shipbuilding Plant, River Rouge, Mich. Am. Architect, vol. 115, no. 2259, Apr. 9, 1919, pp. 526-529, 9 figs. Operation in assembled shop. Boats are assembled on a line of trucks moving on standard-gage railroad tracks.

Framing, Millar System

SS. "Clan MacWilliam." Shipbuilding & Shipping Rec., vol. 13, no. 13, Mar. 27, 1919, pp. 375-376, 3 figs. Construction on Millar's patent system of framing. Deadweight 10,250 tons, on 26 ft. $10\frac{1}{2}$ in. draft.

German Shipbuilding

German Shipbuilding and the Revolution. Shipbuilding & Shipping Rec., vol. 13, no. 13, Mar. 27, 1919, pp. 373-374. Competition with foreign yards deemed impossible.

Halifax Shipyards

Halifax Shipyards Embraces Old and New Industry. Mar. Eng. of Canada, vol. 9, no. 3, Mar. 1919, pp. 97-99, 3 figs. Plant equipped with graving dock and deep-water wharf, also marine railway.

Vickers, Canadian Plant

Canadian Vickers have Well-Equipped Plant. Mar. Eng. of Canada, vol. 9, no. 3, Mar. 1919, pp. 89-93, 5 figs. Growth of shipbuilding industry on banks of St. Lawrence.

Welding

Electric Welding as Applied to Ship Construction, H. Jasper Cox. Mech. Eng., vol. 41, no. 5, May 1919, pp. 439-444, 11 figs. Variables which affect efficiency of weld. Investigations to determine possibility of application of electric welding to shipbuilding. General scope of experiments included principally determination of modulus of elasticity and approximate elastic limit; ultimate strength and ultimate elongation; application of alternating stresses with (a) rotating specimens, (b) stationary test pieces. Paper presented before Soc. Naval Architects and Mar. Engrs.

Electric Welding Applied to Shipbuilding, J. H. Collie. Elecn., vol. 82, no. 15, Apr. 11, 1919, pp. 421-427, 22 figs. After reference to general systems of welding that are available, writer describes particular systems now mostly in use and then passes on to the question of testing electric welds.

Wooden Ships

Building Wooden Ships for French Government. Mar. Eng. of Canada, vol. 9, no. 3, Mar. 1919, pp. 94-96, 7 figs. General layout of Montreal plant.

See also MECHANICAL ENGINEERING, Hoisting and Conveying (Cranes).

Industrial Technology

Acetylene Products

Principal Organic Compounds Derived from Acetylene (Les principaux composés organiques dérivés de l'acétylène), D. Florentin. Génie Civil, vol. 74, no. 12, Mar. 22, 1919, pp. 235-236. Industrial synthesis of alcohol, acetic acid, acetic anhydride and the acetic ethers. (Concluded).

Ammonium Nitrate

Effecting and Controlling Crystallization of Ammonium Nitrate, J. Esten Bolling. Chem. & Metallurgical Eng., vol. 20, no. 8, Apr. 15, 1919, pp. 401-405, 9 figs. Crystallizing process employed at U. S. Ammonium Nitrate Plant. Survey of air conditioning features involved and their relation to entire process of refrigeration.

Ammonium Sulphate

Manufacture of Ammonium Sulphate from Cyanamide (La fabrication du sulfate d'ammoniaque en partant de la cyanamide). Journal du Four Electrique, vol. 28, no. 6, Mar. 15, 1919, pp. 44-46. Cyanamide is decomposed by water under pressure; the ammonia gas is then brought in contact with dilute sulphuric acid.

Benzol

Manufacture of Benzol in Sestao Iron Works (Fabricaion de benzol en la fabrica de hierro de Sestao). Revista Minera, vol. 70, no. 2678, Mar. 1, 1919, pp. 105-107. Process followed, with remarks on adaptation of installation to coke furnaces.

By-Products

Importance of By-Products During the War, C. G. Atwater. Gas Age, vol. 43, no. 7, Apr. 1, 1919, pp. 339-343, 5 figs. Light oil stills and accessory plant of Barrett Co.

Coal By-Products

Coal: Its Value as a Raw Material for Distillation Products—II, J. A. Wilkinson. South African Jl. Industries, vol. 2, nos. 1 and 2, Jan. and Feb. 1919, pp. 74-85 and 178-185. Liquid distillation products of coal and processes by which they are obtained. Feb. Distillation of coal tar, oils and pitch.

Coal and Gas-Tar Derivatives of Growing Importance, C. W. Botkin. Colorado School of Mines, Mag. vol. 9, no. 4, Apr. 1919, pp. 78-80, 3 figs. Chart indicating from whence these materials are derived, with description of their nature, properties and method of manufacture.

Carbonizing Processes and Coal Utilization and Conservation, W. A. Bone. Gas Journal, vol. 145, no. 2915, Mar. 25, 1919, pp. 632-635. Uses of coal in the United Kingdom in 1913. Works in which writer believes complete by-products recovery is possible; commercial prospects for low temperature carbonization. Address delivered before Roy. Soc. of Arts.

Coated Paper

Casein and Coating Mixtures, E. Sutermeister. Paper, vol. 24, no. 7, Apr. 23, 1919, pp. 15-80 & 50. Suggestions for overcoming brush marks and froth pits in manufacture of coated paper.

Decolorizing Carbons

Investigations on Vegetable Decolorizing Carbons, using "Carboraffin," Vl. Stanek. Int. Sugar Jl., vol. 21, no. 244, Apr. 1919, pp. 168-171, 1 fig. Preparation of vegetable carbons from cellulose according to Austrian patent and their use in sugar refineries. "Carboraffin" is said to be so powerful that its effect equals that obtained with 8-15 per cent of annual charcoal. From Tijdschrift der Vereeniging van Beetwortelsuikkerfabrikantem no. 8, 1919, pp. 116-122.

Ethylene

Ethylene, William Malisoff and Gustav Egloff. Jl. Phys. Chem., vol. 23, no. 2, Feb 1919, pp. 65-138. Collection of data on ethylene, covering physical and chemical properties; formation in chemical reactions by decomposition; decomposition; catalysis; analytical and biological data; research possibilities.

France

France's Chemical Industries as they are, Camille Matignon. Chem. Engr., vol. 27, no. 3, Mar. 1919, pp. 55-58. France is said to be fully equipped with series of chemical industries competent to supply the most of the republic's chemical needs.

Fulminate of Mercury

Determination of Impurities in Fulminate of Mercury (Recherches sur le fulminate de mercure et quelques-unes de ses impurités), Paul Nicolardot and Jean Boudet. Bul. Société Chimique de France, vols. 25-26, no. 3, Mar. 1919, pp. 119-122. Results of utilizing sodium hyposulphite in treatment of residues in manufacture of fulminate.

Gallium

The Purification of Gallium by Electrolysis, and the Compressibility and Density of Gallium, Theodore W. Richards and Sylvester Boyer. Jl. Am. Chem. Soc., vol. 41, no. 2, Feb. 1919, pp. 133-134. Examination of methods recommended by various writers.

Glass

Optical Glass. Nature, vol. 103, no. 2578, Mar. 27, 1919, pp. 65-67, 3 figs. Developments in manufacture of homogeneous glass, particularly during time of war.

The Technique of Optical Glass Melting, Clarence N. Fenner. Jl. Am. Ceramic Soc.,

vol. 2, no. 2, Feb. 1919, pp. 102-145, 7 figs. Activities of Geophysical Laboratory in its work of coöperation with manufacturers of optical glass.

An Improved Method of Optical Glass Manufacture, George W. Morey. Jl. Am. Ceramic Soc., vol. 2, Feb. 1919, pp. 146-150. Modification of filling operation to prevent surface becoming high in silica.

Light, Ultra-Violet

Ultra-Violet Light in the Chemical Arts XXIII, Carleton Ellis and A. A. Wells. Chem. Engr., vol. 27, no. 3, Mar. 1919, pp. 73-74. Further conclusions regarding absorption spectra of some of primary alcohols, and of confectionary colors and dyes.

Light Oils

What Can Be Done with Light Oil Plants, W. H. Fulweiler. Gas Age, vol. 43, no. 8, Apr. 15, 1919, pp. 415-417, 1 fig. Fifty plants for recovery of toluene from illuminating gas were built during war. Article discusses possibility of utilizing these plants for recovery of light oils from illuminating gas in competition with gasoline for motor fuel. Paper read before Am. Gas. Assn.

Nitric Acid

The Theory of Absorption Towers for Nitric Acid Manufacture, J. R. Partington and L. H. Parker. Jl. Soc. Chem. Indus., vol. 38, no. 6, Mar. 31, 1919, pp. 75T-80T, 2 figs. Efficiency of a tower system said to depend on two factors, rapidity and completeness of absorption and concentration of solution produced.

Pitch

The Softening Point of Pitch, Percy E. Spielmann and G. Campbell Petrie. Jl. Soc. Chem. Indus., vol. 38, no. 6, Mar. 31, 1919, pp. 68T-70T, 2 figs. Attempt to characterize it by numerical value. Recourse was had to biting test, change of appearance, twisting test, bending and sagging dropping tests.

Rubber, Synthetic

Development of Artificial Rubber During the War (Die Entwicklung des Künstlichen Gummis im Kriege), Dr. Duisberg. Kunststoffe, vol. 8, no. 11, June 1, 1918, pp. 121-122. The carbide process: Acetylene obtained from calcium carbide and water is changed into acetaldehyde and this is oxidized into acetic acid; this latter, when blown over a contact substance, yields acetone, carbonic acid being split off during the process.

Salt

The Recovery of Salt from Sea-Water, F. H. Mason. Min. & Sci. Press, vol. 118, no. 16, Apr. 19, 1919, pp. 528-530, 4 figs. Process followed by Western Salt Co. at San Diego, Cal.

Sampling (Pulp)

Sampling Practice at Independence Mill, Claude T Rice. Eng. & Min. Jl., vol. 107, no. 15, Apr. 12, 1919, pp. 641-644, 6 figs. Some of features are mechanical bucking apparatus and sample mixer and divider, both of which devices are said to have proven satisfactory for final handling of pulp.

Selenium

Selenium and Its Present Uses (Le Sélénium et ses applications actuelles), Louis Ancel. Chimie & Industrie, vol. 2, no. 3, Mar. 1, 1919, pp. 245-259, 14 figs. Occurrences and properties of selenium in various allotropic states; its utilization in biological chemistry, glass and caoutchouc industries, electrical apparatus and electrochemistry.

Silicon Tetrachloride

Silicon Tetrachloride, Otis Hutchins. General Meeting Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 18, pp. 245-256. Experimental work undertaken by electrochemical plant in developing commercial process for preparing silicon tetrachloride.

The Role Played by Silicon and Titanium Tetrachlorides During the Past War, G. A. Richter. General Meeting Am. Electrochemical Soc., Apr. 3-5, 1919, paper no. 13, pp. 187-195. Physical properties of these chlorides and study of their reaction with moisture, or with ammonia gas, or with both, to produce smoke clouds; ship apparatus and trench apparatus used for producing smoke clouds.

Sugar

The Loss of Moisture from Sugar Samples Under Different Methods of Preservation, C. A. Browne and G. H. Hardin. La. Planter & Sugar Mfr., vol. 62, no. 15, Apr. 12, 1919, pp. 233-234. Table of changes in moisture and polarization of sugar samples in unsealed tin cans; compiled from data obtained in N. Y. Sugar Trade Laboratory. Paper before Am. Chem. Soc.

Sulphuric Acid

The Sulphuric Acid Industry, M. Rindl. South African Jl. Industries, vol. 2, no. 2, Feb. 1919, pp. 125-134. Production, uses, grades, prices, manufacture in Union of South Africa.

Erection of Huge Sulphuric, Nitric, Mixed Acid and Denitrating Plant under War Pressure, H. E. and C. E. Hollister. Chem. & Metallurgical Eng., vol. 20, no. 8, Apr. 15, 1919, pp. 406-412, 11 figs. Construction of one of the largest acid plants in the country, under adverse climatic conditions and insufficient transportation facilities.

Tanning Materials

Notes on Australian Tanning Materials and the Manufacture of Sole-Leather, F. A. Coombs. Jl. Soc., Chem. Indus., vol. 38, no. 6, Mar. 31, 1919, pp. 70T-74T. Comparative tests conducted at Sydney Technical College to ascertain value of tannins in barks of E sideraphloia.

Tar Distillation

Tar Distilleries (Les distilleries de goudron), W. Solton. Journal des Usines à Gaz, vol. 43, no. 7, Apr. 5, 1919, pp. 97-104, 13 figs. Machines and process of distillation followed by Sulzer Frères of Winterthur. From Bulletin Technique de la Suisse Romande, no. 16, Aug. 11, 1917.

Water Gas

Bituminous Generator Fuel, R. G. Krumrey. Gas Rec., vol. 15, no. 7, Apr. 9, 1919, pp. 217-220, 1 fig. Comparison of operating data and results for coke and coal as generator fuel in a water-gas machine. Paper read at Wis Gas Convention.

Railroad Engineering

BRAKES

Straight Air Brake, Automatic

The Automatic Straight Air Brake. Ry. Mech. Engr., vol. 93, no. 4, Apr. 1919, pp. 195-198. Series of tests conducted by Bur. of Safety of the air-brake system of Automatic Straight Air Brake Co. of N. Y.

ELECTRIC RAILROADS

Electropneumatic Driving Mechanism

Westinghouse Electro-Pneumatic Driving Mechanism of the Suburban Locomotives Used by the State Railways (Equipment Westinghouse pour la commande électro-pneumatique des automotrices de banlieue des chemins de fer de l'Etat), L. Pahin. Industrie Electrique, vol. 28, no. 643, Apr. 10, 1919, pp. 128-131, 6 figs. Scheme of connections and diagram indicating closing order of the thirteen contacts. (To be continued.)

Relays

A. C. Accessories, A. E. Tattersall. Railway Engineer, vol. 40, no. 471, Apr. 1919, pp. 77-80, 7 figs. . Radial polyphase relays. (Concluded).

See also ELECTRICAL ENGINEERING, *Generators and Motors (Railway Motors).*

ELECTRIFICATION

Argentina

Electrification of the Central Railway of Argentina (Electrificacion del ferrocarril central argentino). Ingenieria Internacional, vol. 1, no. 1, Apr. 1919, pp. 9-13, 4 figs. Details of power house.

Economics

Steam Railroad Electrification, Calvert Townley. Can. Engr., vol. 36, no. 16, Apr. 17, 1919, pp. 387-388. Possibilities of electrification as affecting future railroading policies. Also in Proc. Am. Inst. Elec. Engrs., vol. 38, no. 4, Apr. 1919, pp. 541-547; Ry. Rev., vol. 64, no. 17, Apr. 26, 1919, pp. 615-616.

Railroad Electrification, F. H. Shepard. Southwestern Elecn., vol. 15, no. 2, Apr. 1919, pp. 18-19. Urgency of steam-railroad electrification is argued from viewpoints of economy and service of electrical equipment. Paper presented at Annual Meeting of Eng. Inst. of Canada.

Pantagraph Frames

Railroad Electrification Facts and Factors, A. J. Manson. Ry. Elec. Engr., vol. 10, no. 4, Apr. 1919, pp. 115-117, 6 figs. Construction details of pantagraph frames as determined by operating conditions.

Washington

Railway Electrification in Washington. Jl. Electricity, vol. 42, no. 7, pp. 311-313. Review of present status with description of equipment and construction work.

FOREIGN

Argentina

The Railroad Development of the Argentine—I. Ry. Age, vol. 66, nos. 16 and 17, Apr. 18 and 25, 1919, pp. 1001-1005 and 1047-1050, 8 figs. Difficulties railways have been confronted with in the way of Government regulation, labor and taxation. Possible trend of future developments; figure of imports of railway material and discussion of possible markets for such supplies. Apr. 25: Problems in regulation, labor, and taxation. Article sets forth that largest market for railway equipment is in South America.

Australia

Australian Railways. Indus. Australian & Min. Standard, vol. 61, nos. 1582, 1583 and 1584, Mar. 6, 13 and 20, 1919, pp. 420-421 and 509, 463, 7 figs. General dimensions of Tasmanian and Western Australian types. Mar. 13: Queensland types of locomotives.

English Channel Tunnel

The English Channel Tunnel. Sci. Am., vol. 120, no. 16, Apr. 19, 1919, pp. 398-399 and pp 416-417, 5 figs. Plans for tunnel, showing its course, geological strata and system of drainage; also plans for tubes and a bridge.

The Channel Tunnel Scheme, A. E. Ritchie. Iron & Coal Trades Rev., vol. 98, no. 2666, Apr. 4, 1919, pp. 403-404, 4 figs. Details of proposed scheme.

Europe

European Train Speeds. Ry. Gaz., vol. 30, no. 14, Apr. 4, 1919, pp. 607-609, 3 figs. Survey of highest, longest and fastest non-stop runs, speed of trains between two places and geographical distribution of important services. (Continuation of serial.)

Foreign Developments

Railway Developments in Foreign Countries. Ry. Age, vol. 66, no. 15, Apr. 11, 1919, pp. 957-962, 2 figs. Problem of unification of railways in China; shortage of railway equipment in Germany; electric railway projected from Stockholm to Goteborg; cross-section of proposed English Channel tunnel.

Railway Developments in Foreign Countries. Ry. Age, vol. 66, no. 17, Apr. 25, 1919, pp. 1056-1059. In Chile, Uruguay and China.

Spain

An Important Development in the Railways of Spain—III, F. Lavis. Ry. Age, vol. 66, no. 15, Apr. 11, 1919, pp. 945-949, 3 figs. Proposed direct line from France to Gibraltar through Madrid and its relation to other railways of Europe and those of South America.

Uruguay

The Railways of Uruguay, William A. Reid. Ry. Rev., vol. 64, no. 16, Apr. 19, 1919, pp. 583-586, 7 figs. Agricultural interests served by three main systems.

LOCOMOTIVES

Boiler Power and Tractive Power

Boiler Power Versus Tractive Power—I, William N. Allman. Boiler Maker, vol. 19, no. 4, Apr. 1919, pp. 106-108. Expressions for deriving tractive power for single-expansion locomotives.

Electric Locomotives

See Electric Railroads.

Feedwater Heaters

Feed Water Heaters and Their Development—H. J. Snowden Bell. Railroad Herald, vol. 23, no. 5, Apr. 1919, pp. 109-112. From 1825-1840. (Continuation of serial.) Paper read before Am. Ry. Master Mechanics' Assn.

Firing

Modern Locomotive Engine Design and Construction—XLVII. Railway Engineer, vol. 40, no. 471, Apr. 1919, pp. 69-77, 15 figs. Special methods of boiler firing: Liquid fuel; pulverized fuel.

Flues

Flues, George L. Price. Boiler Maker, vol. 19, no. 4, Apr. 1919, pp. 98-99. Methods employed in installing flues in stationary and locomotive boilers.

Gasoline-Electric Locomotive

Locomotive Notes and News, C. S. Lake. Model Engr. & Elecn., vol. 40, no. 936, Apr. 3, 1919, pp. 225-227, 3 figs. Gasoline-electric

They Can Be SEALED!

"ADJUSTABLE in the toolroom — SOLID in the hands of operators and inspectors." That's ohansson Limit Snap Gages.

For when a Johansson Snap has been set, it can also be SEALED.

Just melt sealing wax into the heads of the screws and stamp the seale:'s mark—it's just as much a solid gage then as though made of a single piece. Cannot be changed or tampered with in any way without breaking the seal. And then you know who's who.

Johansson Snaps are made to be used SEALED.

And with thousands of them in use every day on all kinds of big production and inspection, we never hear of work being spoiled because the gage changed size. he fact is, they don't change size. They can't; they are adjusted, set and sealed by responsible hands and when sent out in the shop they retain their size.

When worn, they are quickly *reset* and *resealed* and are put back on the job with a minimum of time lost.

Twenty-one sizes give all dimensions up to 12 ins. Revised price list (No. 3) now ready.

Johansson

C. E. JOHANSSON, INC., 245 West 55th Street, New York City

SUCCESSOR TO SWEDISH GAGE COMPANY, Inc.

Canadian Address: 72 Queen St., West, Toronto

locomotive designed to haul 100 tons on the level, and built to run on 2-ft. gage. It is equipped with a 45-hp. four-cylinder gasoline engine, which drives through a flexible coupling, a 30-kw. ventilated-type direct-current generator.

Hanger Levers

General Observations of the Design of Hanger Levers for Locomotives, Victor M. Summa. Ry. & Locomotive Eng., vol. 32, no. 4, Apr. 1919, pp. 103-105, 5 figs. Stresses in a plain flat-bar lever subjected to forces lying in plane of bar.

Mallet

Latest Mallet Type of Locomotive for the Southern Railway—Baldwin's Fifty-Thousandth Engine. Ry. & Locomotive Eng., vol. 32, no. 4, Apr. 1919, pp. 97-99, 2 figs. Articulated type with 2-8-8-2 wheel arrangement in operation on Southern railway. Also in Ry. Jl., vol. 25, no. 5, May 1919, pp. 17-21, 4 figs.

P. & R. 2-8-2

P. & R. Large 2-8-2 Type Locomotive. Ry. Mech. Engr., vol. 93, no. 4, Apr. 1919, pp. 175-177, 5 figs. Tractive effort is 61,260 lb.; boiler has combustion chamber and 2-in. tubes 13 ft. 6 in. long.

French Express Locomotives

The Development of Express Locomotives in France, M. Herdner. Engineer, vol. 127, no. 3299, Mar. 21, 1919, pp. 270-272, 9 figs. From 1878-1918. Presidential address before Société des Ingénieurs Civils de France.

Standard Locomotives

Light and Heavy Standard Pacific Type Locomotives. Ry. Age, vol. 66, no. 15, Apr. 11, 1919, pp. 950-954, 10 figs. Railroad Administration Standard designs having details interchangeable with other types.

Standard 2-8-8-2 Type Locomotives. Ry. Mech. Engr., vol. 93, no. 4, Apr. 1919, pp. 187-190, 5 figs. Locomotive is 6000 lb. heavier than that built by the Norfolk & Western; working steam pressure is 240 lb. per sq. in. tractive effort, compound, is 106,000 lb.

OPERATION AND MANAGEMENT

Accounting

Railway Accounting of Carriage Paid Goods Train Traffic, L. C. Webber Reed. Ry. Gaz., vol. 30, no. 13, Mar. 28, 1919, pp. 564-565. Arguments in favor of economies which writer claims would be effected if it were made compulsory that all freight-train traffic should be consigned carriage paid.

Car Equipment, Inspection and Maintenance

Unification of Inspection and Maintenance of Car Equipment, J. J. Tatum. Official Proc. Central Ry. Club, vol. 27, no. 2, Mar. 1919, pp. 575-579 and (discussion) pp. 579-606. Selection of inspectors; their duties and responsibilities.

Lighting

Railway Lighting and Its Maintenance, A. Cunnington. Ry. Gaz., vol. 30, no. 12, Mar. 21, 1919, pp. 525-527. Standardization of lamps; illumination measurements; system of distance control. Paper read before Illuminating Eng. Soc.

Road Motor Vehicle Department

Organization of a Railway Company's Road Motor Vehicle Department. Ry. Gaz., vol. 30, no. 15, Apr. 11, 1919, pp. 639-645, 16 figs. Practice of Great Western R.R.

San Diego & Arizona Railway

Heavy Railway Construction Along Mexican Border. Ry. Age, vol. 66, no. 15, Apr. 11, 1919, pp. 931-934, 5 figs. Construction of San Diego & Arizona Ry.; seventeen tunnels are being driven in 11-mile gap.

Train Loading

Securing the Maximum Efficiency in Train Loading, T. H. Williams. Ry. Age, vol. 66, no. 17, Apr. 25, 1919, pp. 1051-1053. High ratio of actual tonnage moved to rating of engines. Heavy loading promotes fuel economy. Paper presented before Pac. Ry. Club.

Train and Engine Loading, T. H. Williams. Ry. Rev., vol. 64, no. 14, Apr. 5, 1919, pp. 507-508. Discussion of subject in regard to means for keeping up practice of loading engines up to full rating and losses accruing when such practice is not followed closely.

PERMANENT WAY AND BUILDINGS

Curvature

Effect of Curvature on Railway Maintenance of Way. Eng. & Contracting, vol. 51, no. 16, Apr. 16, 1919, p. 397, 1 fig. Graph indicating relation between wear of rail on straight line as compared with that on curves.

Slip

The Slip at Wembley Cutting, Great Central Railway. Ry. Gaz., vol. 30, no. 12, Mar. 21, 1919, pp. 528-534, 17 figs. Measures for reconstructing embankment and restoring traffic through cutting. Slip occurred in portion of cutting where maximum depth is about 60 ft.

Ties

Zinc Chloride Treatment for Railroad Ties. Eng. & Contracting, vol. 51, no. 16, Apr. 16, 1919, pp. 394-395. Influence of conditions of wood before treatment; leaching of zinc salt. From report of Committee on Wood Preservation of Am. Ry. Eng. Assn.

The Preservation of Railway Ties, H. K. Wicksteed. Can. Ry. & Mar. World, no. 254, Apr. 1919, pp. 174-176. Process based on coating to exclude moisture.

Track Reclamation

The Reclamation of Electric Railway Track by Welding and Grinding, H. Jackson Tippett. Elec. Ry. Jl., vol. 53, no. 16, Apr. 19, 1919, pp. 773-776, 9 figs. Adaptability of various types of welding and grinding equipment to prevent rapid deterioration of rail joints, particularly of those in paved streets. Paper read before Conn. Soc. Civil Engrs.

Tunnel, Mount Royal

The Mount Royal Tunnel, J. L. Busfield. Jl. Eng. Inst. of Canada, vol. 2, no. 4, Apr. 1919, pp. 267-298, 40 figs. Construction of tunnel and terminal for Canadian railway at Montreal; tunnel is 16,315 ft. long and its construction required the excavation of 422,358 cu. yd. of rock.

RAILS

Stresses in Rails

Stresses in Rails (Détermination des efforts développés dans le métal des rails des voies ferrées), T. Godard and M. Pigeaud. Annales des Ponts et Chaussées, partie technique, vol. 47, no. 6, Nov.-Dec. 1918, pp. 273-327, 8 figs. Formulæ for determining stresses due to supports not being on same level. Expressions are applicable when loads acting are or may be considered as static. A criticism is offered on Cuard's conclusions in this direction.

ROLLING STOCK

Coal-Hopper Cars

Broad Gauge Steel Coal Hopper Cars Built in Canada for Bengal-Nagpur Railway. Can. Ry. & Mar. World, no. 254, Apr. 1919, pp. 169-170. Some of general dimensions are: Length over buffers, 41 ft. 3 in.; length over end sill, 37 ft. 1 in.; length of body inside, 35 ft.; capacity 100,000 lb.

Concrete Gondola Cars

Reinforced Concrete Gondola Cars. Eng. World, vol. 14, no. 7, Apr. 1, 1919, pp. 45-46, 2 figs. Design in accordance with U. S. R. R. Administration standards as a 100,000-lb. capacity coal car, plus 10 per cent for overload. Also in Ry. Mech. Engr., vol. 93, no. 4, Apr. 1919, pp. 193-195, 3 figs.

Lumber for Freight Cars

Treated Lumber for Freight Cars. Ry. Mech. Engr., vol. 93, no. 4, Apr. 1919, pp. 198-200. Method of treating wooden parts of car construction.

SAFETY AND SIGNALING SYSTEMS

Automatic Train Control

Automatic Train Control on the Chesapeake & Ohio R.R. Ry. Rev., vol. 64, no. 14, Apr. 5, 1919, pp. 541-546, 9 figs. System installed is that of Am. Train Control Co. of Baltimore. Description of system and account of tests performed. Also in Ry. Signal Engr., vol. 12, no. 4, Apr. 1919, pp. 131-134, 7 figs.

Signal Failure

I. C. C. Report on the Collision on the Frisco. Ry. Signal Engr., vol. 12, no. 4, Apr. 1919, pp. 126-129, 4 figs. Accident reported to have been caused by dispatcher failing to transmit train order and engineman to obey signal indication.

Specifications

Specification for Electric Motor, Switch Operating and Locking Mechanism. Ry. Signal Engr., vol. 12, no. 4, Apr. 1919, p. 113. Concerns operating requirements, general design, dielectric tests, bearings and paint. Prepared by Committee of Am. R. R. Assn.

Specifications for Power Interlocking Machine. Ry. Signal Engr., vol. 12, no. 4, Apr. 1919, pp. 114-115. Prepared by Committee of Am. R. R. Assn.

SHOPS

Columbus Roundhouse

A Complete Modern Engine Terminal Installation. Ry. Age, vol. 66, no. 16, Apr. 18, 1919, pp. 994-997, 8 figs. Reinforced-concrete 20-stall roundhouse of Toledo & Ohio Central at Columbus.

Re-Boilering of Locomotives

The Re-Boilering of Locomotives. Ry. Gaz., vol. 30, no. 13, Mar. 28, 1919, pp. 575-576, 2 figs. Work done in shops of London & N. W. R.R.

Torrance Shops

New Car Shops at Torrance, Clifford A. Elliot. Elec. Traction, vol. 15, no. 4, Apr. 15, 1919, pp. 234-238, 3 figs. For the repairing and overhauling of equipment and the building of box cars.

Welding

Oxy-Acetylene Welding in Railroad Shops, W. L. Bean. Ry. Jl., vol. 25, no. 5, May 1919, pp. 21-23. Concerning ease and efficiency of operation. Also in Ry. Rev., vol. 64, no. 14, Apr. 5, 1919, pp. 513-515.

Spot Welding Applied to Railroad Tinware. Ry. Elec. Engr., vol. 10, no. 4, Apr. 1919, pp. 127-128, 3 figs. Process followed by Illinois Central.

SPECIAL LINES

Rack Railways

Rack Railways (Ferrocarriles de cremallera), Fabio González Tavera. Anales de Ingenieria, vol. 26, nos. 309 and 310, Dec. 1918 and Jan. 1919, pp. 137-147. Weight of locomotive in terms of total weight of train to be pulled up a given slope. Riggenbach, Bissinger, Abt, Strub, and Locher types of rack.

STREET RAILWAYS

Concrete Stations

Shelters and Stations on Pacific Electric's Interurban Lines, Clifford A. Elliott. Elec. Ry. Jl., vol. 53, no. 15, Apr. 12, 1919, pp. 733-734, 5 figs. Unit-slab concrete structure.

Subway Stations

Philadelphia City Hall Subway Station, Harry Gardner. Eng. World, vol. 14, no. 7, Apr. 1, 1919, pp. 15-22, 12 figs. Details of supports showing series of I-beams, girders and concrete construction.

Zone Fares

Zone Tickets Adopted for Portland. Elec Ry. Jl., vol. 53, no. 15, Apr. 12, 1919, pp. 728-731, 2 figs. Fare system is based on central zone from 2.5 to 4 miles in radius and subdivision of all exterior lines into zones of varying length.

The Zone Fare in Practice—Aberdeen, Walter Jackson. Elec. Ry. Jl., vol. 53, no. 17, Apr. 26, 1919, pp. 814-822, 17 figs. Combination zone and universal fare in city of 165,000 is claimed to stimulate both short-haul and long-haul riding.

Sewell's Point Virginian Railway

The Virginian Ry. Co.'s Pier, Sewell's Point—I. Coal Trade Jl., vol. 50, no. 16 and 17, Apr. 16 and 23, 1919, pp. 404-406, 445-447, 7 figs. Plant includes double car dumper capable of handling two 60-ton railroad cars at the same time, completing cycle in 2 min. Apr. 23: Coal from the mines is dumped into self-cleaning and self-propelling transfer cars of 120 tons capacity for dumping, cars are raised to required level by transfer-car elevator.

Spring Meeting of the A. S. M. E.

This Meeting, Held at Detroit, June 16-19, Was Featured by a Large Attendance, Extended Discussion on Aims and Organization, and Sessions on Research, Industrial Relations and Pulverized Fuel. Many Entertainment Features

WERE it not that the phrase is devoid of any idea of superlatives, the expression "a well-balanced meeting" would correctly characterize the Detroit meeting of The American Society of Mechanical Engineers, held June 16 to 19. The meeting was remarkably well balanced, both in respect to variety of subjects discussed and in the relation which these features bore to the entertainment provided by Detroit's hospitable citizens. It was, however, also a meeting of big things and peak loads. Whenever a high point was registered in one direction, it was immediately followed by an event of corresponding magnitude in some other direction, and so throughout the four days of the meeting there was a rapid succession of occurrences of the greatest interest.

The meeting started on high gear, full speed, on the very first day, over 250 arrivals having been registered on Sunday night and many more the next morning for the Business Meeting which was held on Monday afternoon. Somewhere in the impelling force there was a "hot spot" (this does not refer to the weather, although it might properly do so), which kept up a rapid acceleration of events and produced smooth running throughout the whole period. Every indication pointed to this as being located in the vicinity of the City Hall.

The total registration was 1180, the largest of any Spring Meeting, of which 638 were members and 542 were guests. In 1895, when the Society first met in Detroit, the registration was 132; and again in 1908, 265. This is indicative both of the growth of the Society and the interest of its membership, and of the growth and popularity of Detroit itself, which one of the soldiers returning from France has said he found, when in Europe, to be "the most-talked-of American city." It was obviously a city that the members of the Society desired to visit, and to say that all left immeasurably pleased with the opportunities afforded them for pleasure or profit is but to summarize the sentiments freely expressed by those in attendance.

Features of the Meeting

The dominating feature of the meeting was the discussion of the Report of the Aims and Organization Committee summarized in this number. This began on Monday afternoon and continued on Tuesday and Wednesday. It was a new thing in the annals of an engineering society to have so many members eager to discuss the professional work and opportunities of the Society itself and for its members in general in relation to their profession and the public at large.

Three of the professional sessions also drew large audiences, one of these, the opening session, being on the subject of Research and lasting all day. This again shows the awakening interest of engineers in conditions resulting from the war and an appreciation by them of the need for research work in the development of American industries. A session on Industrial Relations, in which the human side of industrial management was developed, evoked so much enthusiasm that a resolution was passed at its conclusion calling for a continuance of the discussion at the Annual Meeting. On Thursday morning, at the conclusion of the meeting, one of the largest audiences gathered for a discussion on pulverized fuel, although several important excursions, which also were largely attended, were scheduled at the same hour.

Headquarters of the American Society of Mechanical Engineers, Detroit Meeting, June 16-19, 1919

Business Meeting

Unlike previous years, the business meeting was held on the opening day, occurring this year on Monday afternoon. Pres. Mortimer E. Cooley presided, and, after expressing his pleasure at the choice of Detroit as a meeting place, called for the report of the tellers of election. This report, which was presented by Secretary Calvin W. Rice, embodied the following amendment to the constitution:

C48 There shall be a Nominating Committee, whose duty shall be to select candidates for the elective offices to be filled at each election. This Committee shall be elected annually by the voting membership of the Society. Other Nominating Committees having the same powers may be constituted by the voting membership. The number of members, the selection, organization and procedure of all Nominating Committees shall be as the By-Laws shall provide.

This amendment had already been voted upon by the membership, and the chairman accordingly declared it to be a law of the Society.

The report of the Boiler Code Committee was next presented by John A. Stevens, Chairman. This report, which was presented by title only, is a preliminary one covering the rules for the construction of boilers of locomotives which are not subject to Federal inspection and control. It is intended to form Section III of Part I of the present well-known Boiler Code, and was accepted without any discussion.

Progress reports were then presented by the Sub-Committee on Bearing Metals, and the Sub-Committee on Lubrication. These were also presented by title only, as they were available in printed form and had been accepted by the Council. C. H. Bierbaum is chairman of the Sub-Committee on Bearing Metals and Albert Kingsbury chairman of the Sub-Committee on Lubrication.

The meeting next proceeded with what the chairman characterized as "perhaps the most important business this Society has had for consideration in many years." This was the report of the Committee on Aims and Organization, of which Louis C. Marburg is chairman.

Before presenting his report, Mr. Marburg called attention to the fact that a joint committee of the four national engineering societies on Aims and Organization had been created, and that a meeting of this committee was to be held in New York on July 2. "The coöperation among the various committees of development is very close," said Mr. Marburg. "We are in continual contact, and it is remarkable how closely the lines of thinking in the different development committees agree."

Address by Frazer S. Keith, Secretary of the Engineering Institute of Canada

Preceding the discussion of the report of the Aims and Organization Committee, the Society had the pleasure of listening to Frazer S. Keith, who together with Mr. John A. Brown and Mr. Riddell were delegated by the Engineering Institute of Canada to attend the convention. Mr. Keith first conveyed the personal regrets of Sir Alexander Bertram and Mr. H. H. Bond, two prominent mechanical engineers of Canada and members of the Canadian Institute, at their inability to accept an invitation to be present, and then spoke of the work of the professional engineering society.

Mr. Keith voiced his belief in the adoption of activities whereby there will be aroused a fervent sense of loyalty on the part of every man who is a member of the profession. "Loyalty," he said, "combined with enthusiasm, is a prime necessity to any cause, and before the engineering profession can become a powerful national organization, its members must be intensely loyal to the profession itself. To the average engineer the national society of which he is a member embodies all that the profession represents to him. Whatever may be the aims and objects of that society, such constitute the engineering profession. If their aims be narrow, likewise will their viewpoint be circumscribed. Now, to create that loyalty there seems to be one sure method, that is, the loyalty combined with an intense professional spirit, which we must all admit, is required, and to accomplish that the promotion of the personal welfare of the members to a greater extent than has been customary in the past, seems to be necessary. When mention is made of one of these methods, that is, assisting to raise the salaries of the rank and file of the engineering profession, by means of adopting a schedule, we immediately hear the cry "Trade Unionism," but it is nothing of the sort.

In Canada we have broadened our vision. We have become cognizant of the fact and have taken it on ourselves to recognize that we have a definite responsibility to the individual member in assisting him in his material welfare, and this, combined with the fact that one of our objects is to enhance the usefulness of the profession to the public, is arousing a professional consciousness and a sense of loyalty greater than ever existed before. It is believed that in direct proportion to the attention which we have given to the material welfare of the members and the endeavor to make the profession useful to the public has loyalty to, and interest in, the profession increased. And, further, as the interest in the profession has increased, so has the influence of the profession developed.

There is another subject which is quite prominent in all engineering bodies. I refer to the question of capital and labor. This is the greatest problem confronting this continent today. Capital cannot solve this problem, and labor cannot solve it, because each is biased. The lawyer cannot solve this problem because his mind is not sufficiently instructed; and the politician cannot solve it because he lacks prospective. To whom, then, must we look for the solution? The mind that can design and construct and place in operation a Panama Canal, a battleship, a big bridge, a power plant, or a modern industrial organization; the mind that goes back to first principles in the solution of any problem—this, gentlemen, is the mind that must be brought to bear upon this important problem, and I believe that here lies one of the greatest opportunities which the engineering profession has ever had presented to it.

Research Session

A session in which deep interest was exhibited due to a realization of the pressing need for advancing the work with which it dealt, was that planned for the morning of Tuesday, June 17, by the Research Committee of the Society, but to which it was found necessary to devote the entire day. Four papers and an address dealing with various phases of the subject were presented: namely, The Present Condition of Research in the United States, by Arthur M. Greene, Jr., Chairman of the Research Committee and who also presided; The Organization and Conduct of an Industrial Laboratory, by A. D. Little and H. E. Howe, of Cambridge, Mass.; Organization and Conduct of a Research Laboratory, by Dr. C. K. Mees, of the Eastman Kodak Co., Rochester, N. Y.; Research Work on Malleable Iron, by Enrique Touceda, of Troy, N. Y.; and an address by Dr. G. H. Clevenger, acting chairman of the National Research Council, on its work in organizing the research activities of the country and especially on the work of its Engineering Division.

In the discussion, which occupied the greater part of the afternoon, H. S. Coleman gave particulars of the organization and work of the Mellon Institute of Industrial Research at Pittsburgh, Dean John R. Allen, director of the research laboratory of the Heating and Ventilating Engineers, outlined briefly its proposed activities. Dr. Z. A. Y. Jeffers dealt with the industrial research work of the Aluminum Castings Co., and Deans Richards, Benjamin and Potter spoke regarding research work carried on at the various state engineering experiment stations. J. R. Bibbins presented a resolution proposed by the Chicago Committee which declared it to be the sense of the meeting that Engineering Council be encouraged to undertake active support of a comprehensive plan and organization of scientific and industrial research, one feature of which calls for the passage of an act and the voting of an appropriation by the present Congress. This resolution, after extended discussion, was carried.

The papers by Professor Greene and Mr. Touceda are published in this issue of Mechanical Engineering. The other

will appear in the August issue, together with a more extended report of the discussion.

Session on Industrial Relations

On Tuesday afternoon there was a very full discussion of certain phases of labor problems which are confronting manufacturers at the present time. The basic paper of the meeting was a report prepared by L. P. Alford on The Status of Industrial Relations, which gave a historical summary of the progressive stages in the development of industrial relations since the period immediately following the Civil War, with emphasis on the new aspects of the question which have arisen as a result of the economic disturbance that has followed the recent world war.

The meeting was opened by an address by Arthur H. Young, Director of the Industrial Relations Department of the International Harvester Company of Chicago, in which he described the successful experience of his company with a shop council whereby the employees participate in certain phases of the management with which they are most concerned. Mr. Young's strong personality and appealing presentation deeply impressed the large audience, and the address opened the way for a strong discussion by several members who gave excellent talks on the topics in which they were particularly interested. The first discussion was by Dr. Otto P. Geier, Director of the Service Department of the Cincinnati Milling Machine Company, who gave a very acceptable address at the Spring Meeting at Cincinnati two years ago on the work of the physician among the employees of a company.

The full report of the Industrial Relations Session is given in this number of Mechanical Engineering.

Sections Session

In accordance with the policy of the Meetings and Program Committee to secure papers characteristic of the engineering work done in the part of the country where the meeting is held, a Sections Session was arranged for Wednesday morning with papers contributed by the Society's sections of the Mid-West.

D. Robert Yarnall, Chairman of the Sections Committee, presided, and the first paper was J. H. Walker, of Detroit, on Central-Station Heating in Detroit. This was followed by a paper on The Production of Liberty Motor Parts at the Ford Plant, by W. F. Verner, also of Detroit. Mr. Verner's paper was illustrated with lantern slides, and these clearly showed the method of manufacturing Liberty motor cylinders and connecting-rod bearings.

The third paper on the program was Fire Engines and the Essentials of Fire Fighting, by Charles H. Fox, of Cincinnati, Ohio. Mr. Fox was unable to be present and his paper was read by the Secretary.

J. M. Spitzglass, of Chicago, presented the final paper on An Electric Device for Measuring the Flow of Fluids in Pipes, which called forth a considerable amount of discussion. There has always been widespread interest in papers on the measurement of the flow of fluids, on which the Society has had numerous contributions, as evidence of which a member—a paper-mill engineer—drove 300 miles to attend this meeting in order to secure the latest data on fluid flow which might be applicable in paper-mill work.

Gas Power Session

The Gas Power Session was held on Wednesday morning with Prof. W. T. Magruder, Chairman of the Sub-Committee on Gas Power, presiding. Three papers were presented, the first being one by J. W. Morton, of Philadelphia, Pa., on Crude-Oil Motors vs. Steam Engines in Marine Practice, which, in the absence of the author, was outlined by F. E. Cardullo.

The second paper, A Suggested Formula for Rating Kerosene Engines, by D. L. Arnold, of Chicago, was presented by title only, but it nevertheless furnished a topic for considerable discussion. Some took exception to Mr. Arnold's suggestion, but others were of the opinion that sooner or later a formula must be adopted which will be intelligible to the average man who is unfamiliar with machinery and mechanics.

The third and last paper of the session, Standards of Carburetor Performance, was presented by its author, Prof. O. C. Berry, of Purdue University. The discussion which followed was concerned chiefly with methods of testing and actual operating conditions. Abstracts of these papers will appear later in Mechanical Engineering, together with a fuller report of the discussions.

Fuel Session

The Fuel Session, which was held on Thursday morning, was practically devoted to a consideration of pulverized coal as a fuel, as two of the three papers presented dealt with that subject. John A. Stevens, a Vice-President of the Society, presided at the meeting. The first paper, Pulverized Coal as a Fuel, was contributed by N. C. Harrison, of Atlanta, Ga. and the second, Pulverized Coal for Stationary Boilers, by F. A. Scheffler and H. G. Barnhurst, both of the Fuller Engineering Company of Allentown, Pa. Mr. Harrison had made an investigation of the pulverized-fuel problem in different parts of the country for his company, the Atlantic Steel Company, and his paper constituted his report to his company.

The latter paper was accompanied by a series of lantern slides showing the different-sized meshes used to screen the fuel, the crushers, magnetic separators, washers, dryers, feeders, etc., and

WHERE THEY CAME FROM

The registration of 1,180 guests and members at the Detroit meeting of The American Society of Mechanical Engineers was the largest at any Spring Meeting in the history of the Society. The registrations at the meetings in Cincinnati and Worcester, which were the largest previous meetings, were 863 and 986 respectively. The representative character of the Detroit meeting, at which there were members or guests present from 29 states and the District of Columbia, besides from Canada and Sweden, is shown by the following summary of the number in attendance from the various states and countries.

	Members	Guests
Alabama	2	1
California	4	...
Connecticut	14	5
Delaware	6	3
District of Columbia	4	1
Georgia	2	1
Illinois	50	22
Indiana	15	16
Iowa	1	...
Kansas	1	...
Louisiana	2	1
Maine	1	1
Maryland	7	4
Massachusetts	38	17
Michigan	184	252
Minnesota	5	...
Missouri	7	4
New Jersey	17	4
New York	119	55
North Dakota	1	...
Ohio	83	82
Oklahoma	1	...
Oregon	1	...
Pennsylvania	45	25
Rhode Island	5	5
Texas	1	2

installations of pulverized-fuel equipment used in connection with boilers of various sizes and designs.

The subject of pulverized coal is unquestionably a timely one and the fourteen men who took part in the discussion which followed the presentation of the two papers made evident the fact that this type of fuel is rapidly becoming more generally adopted in metallurgical work and to a considerable extent in power plants and locomotives, although it has not as yet been proved to be the solution of the many problems arising as a result of a steady decrease in the quality of fuel available. Much of the discussion was naturally of a technical nature and related particularly to the papers presented; and since these will be published later in Mechanical Engineering, further reference to the discussion will be deferred until that time.

The session closed with the presentation by title only of C. R. Weymouth's paper on Economy of Certain Arizona Steam-Electric Power Plants Using Oil Fuel. This paper appeared in abstract form in the June issue (p. 523).

General Session

The General Session was held on Thursday morning, with President Cooley in the chair. Five papers were presented, two, however, by title only. Professor Alphonse A. Adler, of Brooklyn, N. Y., presented the first of these, on The Design of Riveted Butt Joints, and Lieut. J. F. Robbins, U. S. N. R. F., the second, on Mechanical Lifts, Past and Present, and A New Method for Their Balancing.

Walter C. Durfee, of Boston, Mass., next presented his paper on Elements of a General Theory of Airplane-Wing Design, and following the discussion of these three papers the chairman announced the titles of the other two: Air Fans for Driving Electric Generators on Airplanes, by Capt. G. Francis Gray, U. S. A.; Lieut. John W. Reed, U. S. A.; and P. N. Elderkin; and Economical Section of Water Conduit for Power Development, by Cary T. Hutchinson. The first of these papers appeared in abstract form in the April issue of Mechanical Engineering (p. 369) and the second, also abstracted, in the June issue (p. 527).

Excursion to Detroit

About two hundred and fifty members joined in an excursion en route to the Spring Meeting, there being representatives from the principal cities between New England, on the north, and Birmingham and St. Louis on the south. About two-thirds of these gathered at Buffalo on Saturday morning, June 14, where they were met at the train by members of the Buffalo Section who devoted the day to entertaining the visitors, taking them from place to place by automobile. The plants visited included the Lackawanna Steel Company, Larkin Brothers, Lumen Bearing Company, the steam power plant of the Buffalo General Electric Company, the Pierce Arrow Motor Car Company and the National Aniline & Chemical Company.

It is the desire of all those in attendance at the Spring Meeting of the A. S. M. E. at Detroit to express their appreciation to the Detroit Committee for the splendid reception accorded and for the complete and satisfactory way in which the local features of the convention were handled. To the Committee on Meetings and Program, on whom the final responsibility for the program rested, great credit is due; and to the Aims and Organization Committee, the Research Committee, the sub-Committee on Gas Power and the various Local Sections, particularly Detroit, Chicago and Cincinnati, appreciation is due for their contributions to the success of the professional sessions.

In the afternoon special cars were furnished to take the party to Niagara Falls and over the Gorge Route. A few of the members visited some of the hydroelectric plants in preference to taking the scenic ride.

The Buffalo contingent left on the Steamer *City of Erie* arriving at Cleveland Sunday morning, where the group of members who had gathered there the previous day boarded the vessel.

Simultaneously with the visit to Buffalo these other members were being entertained at Cleveland by the members of the Cleveland Engineering Society and the Cleveland Section of the A. S. M. E.

The plants visited at Cleveland included the Pennsylvania Ore Docks, where special arrangements had been made to have a vessel in process of being unloaded; the Upson Bolt & Nut Company, and the Wellman-Seaver-Morgan plant.

On Saturday afternoon, owing to the plants being closed, the party were taken by automobile for a ride through the beautiful park system of Cleveland, arriving at the Cleveland Yacht Club in time for dinner, which was followed by dancing and other entertainment.

The thanks of the Society and the members participating are due to the members at both Buffalo and Cleveland for the painstaking effort and attention which they gave to making both groups feel at home and enjoy their brief stay. These members met the incoming parties at seven o'clock in the morning, and stayed with them throughout the day and evening, and no effort was spared to arrange for their comfort.

Leaving Cleveland the *City of Erie* proceeded to Cedar Point, where a special dinner was served at the Hotel Breakers and opportunity was had for bathing and other recreation. After a rest of four hours at Cedar Point the party boarded the steamer *Put-In-Bay* and proceeded to Detroit, where the boat arrived shortly after 10 p. m. A stop was made at Put-In-Bay, where Commodore Perry fought and won the Battle of Lake Erie. Here was seen the beautiful memorial monument erected in his honor.

Council and Local Sections Luncheon

Sixty Council members and Sections delegates had the opportunity of meeting together at luncheon on Tuesday. Mr. D. Robert Yarnall, Chairman of the Committee on Local Sections, presided, and called upon President Cooley, Past-President Hollis and Lieut.-Col. E. H. Whitlock, the first chairman of the Committee on Local Sections, to make short addresses.

These addresses were of an inspirational character, Dr. Hollis pointing out that the nobility of the engineering profession was dependent upon the degree to which that profession promotes the common good and emphasizing that every engineer should pursue his profession to the end that the world will be just a little bit better for his having lived in it.

Colonel Whitlock gave a brief resume of his experiences in France with the 24th Engineers.

In his opening remarks Mr. Yarnall called attention to the fact that there are now 32 cities where meetings of the Society are being held regularly, seven Sections having been added during the current fiscal year. These are located at Cleveland, Washington, Eastern New York (including Albany, Troy, Schenectady and Watervliet), Rochester, the Mid-Continent Section (with headquarters at Tulsa, Okla.) Virginia Section (with headquarters at Richmond) and a Colorado Section (with headquarters at Denver). The last mentioned was authorized at the Council meeting held in Detroit on June 16. This is an increase of $33\frac{1}{3}$ per cent in the number of Sections, and indicates the extent to which the Section movement is taking hold.

During the convention plans were made to hold during the coming fall a Joint Mid-Sections Meeting at Indianapolis. This was to have been held there last October, but it was interrupted by the epidemic of influenza. The date has not yet been decided, but there will be in addition to a meeting under the auspices of several Sections, a meeting of the Council, and, probably, a dinner and excursions. The meeting will probably be held on October 17 and 18, and should attract a large gathering of members because of the central location of Indianapolis.

Local Sections Committee Meeting

During the course of the meeting the Committee on Local Sections held a five-hour session during which plans for the forthcoming year were discussed, at considerable length. Among other things the Committee will make a comprehensive analysis of the membership by Sections during the summer, and keep closely in touch with a number of localities where the members are contemplating the formation of Sections. A statement is being prepared showing the methods of procedure in the formation of a Section; and the various advantages accruing to the members of the Society and also to the local engineering organizations which may already be established.

Members of any locality interested in holding meetings are encouraged to correspond with the Secretary, and every assistance will be given them in planning an organization meeting.

Entertainment Features

On Monday evening the Local Committee arranged an informal reception in the ballroom of the hotel, with a brief address of welcome by Mayor James Couzens, to which President Cooley replied. The reception was followed by dancing and refreshments, and it may be said here that on all occasions when opportunity afforded, the evident desire of the members to be festive was shown in this way under the leadership of the Chairman of the Local Committee, H. H. Esselstyn, who proved as capable a director of dancing as of other and more weighty affairs.

On Tuesday evening all gathered at the Arena Gardens, the large convention hall at Detroit, which was beautifully decorated. An enjoyable concert was given by the Burroughs Band, and every one felt impelled to join in the dancing which followed. The large floor was well filled until a late hour. Refreshments were served during the evening.

On Wednesday was the crowning event, consisting of the sail on Detroit River and Lake St. Clair and through the St. Clair Flats, the picturesqueness of which delighted everybody. This trip, which lasted throughout the afternoon and evening, gave a rare opportunity for meeting members and friends from all sections of the country. Both the Council and the Sections Committee held meetings during the trip. Dinner was served on the boat, and although the number was large and facilities necessarily restricted, the dinner was excellent and well served.

Many ladies were in attendance at the meeting and the Ladies' Entertainment Committee of Detroit were alert to every possible attention to their guests. Automobile trips were provided, there was a drive around beautiful Belle Isle, luncheon at the Detroit Boat Club, Tea at Red Run Golf Club, and opportunity was offered to inspect many points of interest, including the United States General Hospital, the Art Museum, and Priscilla Inn.

Local and General Committees

The following is a list of the Chairmen of the various local committees which each helped to make the meeting a success and to all of whom the Society desires to express, for the membership, its thanks and appreciation as embodied in the vote of appreciation taken at the closing session. The faithfulness and efficient service rendered by the local members will be long remembered. General Committee, H. H. Esselstyn; Reception, James Couzens; Printing and Publication, John C. McCabe; Transportation and Information, W. E. Cann; Hotel, Thurlow E. Coon, Entertainment, M. W. Taber; Ladies' Entertainment, Mrs. F. G. Ray. The Detroit Local Section committee, E. C. Fisher, chairman, contributed two excellent papers to the meeting.

The work involved in directing the entertainment for so large a convention as this is necessarily very great. The committee members, however, had their work so well organized that every feature was carried through in an admirable manner, without confusion or delay.

The general plan of the meeting as a whole, and the details of the professional program, were under the direction of the Committee on Meetings and Program, Dexter S. Kimball, Chairman.

Trips to Industrial Plants

Unquestionably one of the appealing attractions of Detroit as a place of meeting for engineers is the opportunity for visiting the various industrial plants which have so much of interest.

The first of the regular trips was on Tuesday morning, to the well-known plant of the Burroughs Adding Machine Company, where luncheon was served for the visitors. In the afternoon trips were made to the plant of the Anderson Forge and Machine Company and the calorizing plant of the Diamond Power Specialty Company. On Wednesday morning a large party went to the Connors Creek plant of the Detroit Edison Company, where luncheon was also served. This plant has a number of unusual features, particularly in relation to the operation of the auxiliaries.

On Thursday a large number visited the Ford Eagle plant, where they witnessed the launching of one of these boats. In the afternoon trips were made to the Ford and the Packard plants.

Automotive Engineers See Work Ahead

President Charles W. Manley, in opening the summer meeting of the Society of Automotive Engineers, held at Ottawa Beach, Mich., June 23 to 27, declared that to those having to do with matters of automotive engineering, which includes the designing and building of automobiles, tractors, boats, aircraft and engines, as well as the planning and organization of their operation, the opportunities and obligations knocking at their doors demanded the acceleration of minds and energies to the highest degree. "The real work of the automotive engineer in these fields," President Manley emphasized, "has hardly yet begun. For instance, in the case of the motor truck, these vehicles are daily hauling thousands of tons of merchandize, but the careful study and collection of data for accurately predetermining best operating equipment, organization, and personnel to meet given conditions at a predetermined cost, has hardly been started. This single phase of automotive engineering presents the problems that the determination of freight rates would if all our records and data of railroad transportation were suddenly swept away and it became necessary to reëstablish them."

Professional features of the convention comprised a truck and fuel session, at which were brought out the trend of truck design, and the motor-fuel problem; a passenger-car session devoted mainly to a consideration of the probable characteristics of the car we will be riding in ten years from now; an engine and tractor section, including a paper on the relation of tractor to implement; and an Army and Navy session, divided between a description of the N C Boats and future relations between the automotive industry and various army departments.

The professional sessions were all held in the mornings, the afternoons were left free for sports and recreation, and the evenings were devoted to general meetings and entertainments. The general meetings included a lecture on Wireless Telephony by E. H. Colpitts, Assistant Chief Engineer, Western Electric Company, with a striking demonstration of conversation between the meeting room and the city of Chicago across Lake Michigan.

Dr. John Johnston, formerly secretary of the National Research Council, gave a talk to the Society on Gas Warfare, and Lieut.-Col. A. J. Slade, U. S. A., related experiences with the A. E. F. and the Armistice Commission.

Other distinguished speakers were Major-General C. C. Williams, Chief of Ordnance, Col. L. B. Moody, Chief of the Truck, Trailer and Tractor Division of the Ordnance Department, and Lieut.-Col. B. F. Miller, of the Motor Transport Division.

There were over 600 at the convention, the large Hotel Ottawa being filled to capacity and the overflow accommodated in hotels at Macatawa and Waukasoo, both across the beautiful Black Lake. The selection of the place of meeting was a happy one, and undoubtedly the desire of the Meetings Committee to make the meeting an opportunity not only for real accomplishment but also for plenty of fun was fully realized. A complete account of all features is being published in the forthcoming number of the Journal of the Society of Automotive Engineers.

W. E. B.

Discussion on Industrial Relations

At the largely-attended session on Industrial Relations, held at the Spring Meeting, there was presented the report on The Status of Industrial Relations, by L. P. Alford, an abstract of which was published in MECHANICAL ENGINEERING for June; and an initial, or opening address on Industrial Personnel Relations by Arthur H. Young, Manager of the Industrial Relations Department of the International Harvester Company, Chicago, which is given nearly in full elsewhere in this number. Mr. Young's address and Mr. Alford's report were followed by a general discussion, of which an account follows. A large amount of written discussion was also offered, from which extracts have been made for publication. Because of lack of room it has been impossible to give this discussion in complete form, but it is believed what is here presented correctly records the most essential points that were brought out.

Major Fred J. Miller[1] was of the opinion that the industrial problem resolved itself mainly into the establishment of a business relation between employer and employee of such a character as usually exists between any other classes of people who do business together—relations which must be mutually and permanently satisfactory to each side involved.

The employee must feel that he is doing at least as well as he could do with another employer in the same line, and the employer must feel that he is doing about as well as he could with any other body of employees.

A business relation implies, also, the right of either party to present a proposition at any time for a change in the terms of that relation. It should be agreed that in any negotiations regarding the terms of employment, either side may have the right to be represented by a representative of its own choosing. In these days of large corporations, the owners of a business have chosen, under the name of officers, superintendents, foremen, and so on, men who represent them in all negotiations concerning the business relation that should exist between employer and employee. Nobody disputes the rights of the owners to select such representatives of their own choosing, and if a business relation between employer and employee is to exist, the employees should have exactly the same right to choose their representatives. These may constitute a committee of their own number or they may be union representatives; but so long as they are chosen by the employees they should be treated as their representatives and allowed to state their case.

When an employer has sat down for a discussion across the table with representatives of that sort, whether they be employees of his own or union representatives, or what, and views have been expressed candidly and freely as man to man, it will often be found, as I have actually found, that many of the difficulties which may have been anticipated will disappear; in fact, that thereafter there is no difficulty whatsoever.

An impressive example of this occurred in two factories of which I was at the time general manager, where there was a movement for shorter hours and more pay, although we were already paying about the highest wages that were going. We voluntarily went to the shorter day and gave the men to understand that there could be the utmost freedom in discussing matters relating to the situation but suggested that it would be better if they were to appoint committees of their own number to discuss these matters with us and to present their side, we giving every assurance that no man serving on such a committee should be discriminated against in any way by reason of such service.

There were three classes of employees concerned, tool makers, automatic-screw-machine men and the polishers. The two former appointed committees of their own number of our employees, but the polishers preferred to send a union employee who was not a member of our labor force. He was, however, received just as the committees had been and invited to state his case which he did freely and fully. We stated our case and told him what we could do and what we could not do and why.

When the time for the strike arrived, the tool makers and the automatic-screw-machine men, who had appointed committees of their own, joined the strike, but the polishers did not, although everyone who has had experience with polishers knows that there is likely to be more difficulty in dealing with them than with men of the type of tool makers or screw-machine men. We learned afterward that after his interview this union representative stated at a meeting of the polishers that as a result of considerable experience in adjusting labor matters he had never met those who were quite so ready to hear the other side fairly, squarely and patiently as we had been, and he thought if they knew when they were well off they would hang on to their jobs and refuse to join the strike.

It is safe to say that such a result would not have been prophesied by most people who have had industrial experience; but it is only one of many instances I could relate to show that many of our difficulties which we think are serious in the management of men will disappear if we regard the relation that should exist between employer and employee as one which must be a mutually satisfactory business relation, not a patriarchal relation.

[1] Center Bridge, Bucks Co., Pa.

Forrest E. Cardullo. We have at the present time two conflicting ideas of what constitutes industry. One of these is based on the old idea of competition between all men for the good things of life. It falls back on the proposition that the primary purpose of industry is to make money for the capitalist or owner. Incidently it furnishes a means of livelihood to the worker and in doing so affords the capitalist or owner an opportunity to secure a commodity which he desires, namely, service in exchange for wages. The owner has the primary rights and privileges and the entire control, while the worker is put in the position of competing with his fellow workers in order to dispose of a perishable commodity, service, susceptible only to the operation of the laws of supply and demand.

Now we are coming to a point of view which regards the primary purpose of industry as service to the community and contributory to the general welfare of the nation; while the general welfare of the capitalists, owners, managers and employees who are engaged in the industry becomes secondary.

Our present-day attitude of mind on questions of capital and labor is such that we regard industry as passing from the competitive to the coöperative basis; from the idea of the entire and exclusive control by the owner to the idea of joint control, primarily in the interests of the community. In this we base our ideas on the theory of a democratic government which demands equal rights and privileges for all men. We have the Irishman's fundamental definition of democracy that it is "a form of government where every man is as good as every other man and a damn sight better;" but the trouble in working out the proposition of democracies is that we do not stop at the proper point in the definition, but put in the last clause, which destroys the effectiveness of coöperation and the workability of the definition.

All will admit that every man in the community, no matter what his position, is entitled to certain things such as a normal and healthy physical development; hygienic and sanitary living and working conditions; at least a minimum education which will enable him to discharge intelligently his duties as a citizen; and an equal voice in the control of every activity in which his essential interests are concerned.

Industry is not a war. It is a joint enterprise to be conducted in the spirit of coöperation for the joint benefit of all concerned, whether they be capitalists, managers or workmen.

The defects of the competitive system we have all seen and will continue to see as long as it remains such, which it is liable to do for some time to come. They are (1) that labor is under no moral obligation either to the community or to the employer to give its best, or to coöperate for a joint benefit: and (2) labor believes that it is compelled to adopt forms of organization and

methods of procedure which emphasizes the fighting power of the union and which develop inefficiency rather than efficiency and a spirit of antagonism rather than a spirit of coöperation. The men in charge of the activities of the union are dependent for their support upon fostering, at least, a reasonable amount of friction, so that they may have something to do and may point with pride to their achievements. Before we can do away with this spirit we must substitute not something which will assure to the workmen a larger measure of the good things of life and larger measure of control in the things in which he is interested.

This can only come about gradually and as the result of economic education of the workingman who must understand what he is to strive for, what kind of men he must elect to take care of his interests, and that efficiency must be the basis for any increase in his material welfare.

Dr. Otto P. Geier.[1] There is great need today for trained industrial physicians who will not be satisfied simply to be physicians called in as specialists, but who will actually make a contribution to the solution of some of the very difficult problems that are facing industry today. When we take into account that there is, perhaps, a billion dollars' worth of loss in this country per year, at least half of which is preventable by proper medical supervision in industry, then the problem that looms up for solution by the industrial physician, and by engineers and managers, is worth talking about.

The difficulty that I usually find in discussing this question with managers and industrial engineers is that they have such a poor idea of what contributions industrial physicians can make in the plant. If you hire an industrial physician—a man who is simply a finger wrapper, who sees nothing beyond the mere attempt to repair that injured part, then of course we cannot understand each other. If you have a man who is like a machine making medical examinations for purposes of admission to the plant, or who is only serving part time and is giving his thought to developing his outside practice and merely using industry as a stepping stone, then of course we cannot be talking the same language. Again, if you are talking about a cheap man—and I must confess that I have seen very few high-priced men in industry who are serving as physicians—he is not going to have the large industrial outlook, nor the necessary social outlook. He will have none of the training that comes from broad experience of living and working with people and the result will be what you would get in your engineering department if you hired a cheap man.

Industrial Relations means to me that feeling of responsibility which the farseeing management has; that in having large units of society, such as industry, in its charge it has all the responsibilities that a community has toward large groups; that it must exercise all the care in regard to the matters of health and sanitation and safety, and all the things that naturally come up, and perhaps the thing that has not been stressed today sufficiently is the matter of housing—the matter of living conditions.

Many of you know a man out in the field today, who is a personal service man, who is in overalls, and going from plant to plant in this country trying to find out what workmen are thinking about. I recently spent about five or six hours with him to find out, if possible, what his reaction had been as a result of about four months in overalls, working in coal mines, in steel mills, and doing the things that other men do who earn their money by the sweat of their brow.

Perhaps the thing that he stressed more than anything else was the fact that in spite of all the talk that we have had about sanitation, safety and medical examinations, we haven't even scraped the surface. We are not getting this message across to the workmen, and we haven't begun to realize how much we can do for them by actually caring for their health. Living conditions are the things that are making men start this unrest, and they are coming to the factory in the morning tired and miserable and ill at ease with everybody and the world at large.

[1] Director Employees' Service Department, Cincinnati Milling Machine Co., Cincinnati, Ohio.

Boyd Fisher[2] said that he was interested in presenting the social and economic justification for such a plan as Mr. Young had described, whereby the struggle for control in industry might to some extent be compromised.

The problem of the maladjustment of capital and labor is of interest because such maladjustment reduces production. The public is interested because lessened production increases the cost of commodities; and the manager, engineer and capitalist alike are interested because profits depend on rate of output.

As to labor, the speaker said that it had occurred to him (and he had been held to his viewpoint by Professor Jones of Ann Arbor) that one of the reasons why labor willfully restricts and limits output, although it is one of the partners of production, is because it is the one holding the least advantageous position in the apportionment of the production, and in formulating the rules by which that apportionment is made.

This is due to the fact that those who undertake industry pay off all of the other factors of industry before paying labor. They pay rent and interest, they pay the makers of the tools and suppliers of material, they pay the managers and they pay labor, and then they keep what is left.

These factors, other than labor, are mostly beyond the control of those who undertake industry. The manufacturer cannot control rent, for example, and even his paid managers have a bargaining power fixed in part by market conditions and in part by their ability to stay out of the market if the price offered does not suit them. Labor, on the other hand, has no such advantage and has to come into the market without sufficient resources and reserves and take what the market conditions provide. So it has been, at least, in the past.

Inasmuch, therefore, as capital has to pay off all of the other factors at prices over which it has no full control, at figures that must be satisfactory to the other factors before the bargain is made, and does not have to pay off labor in accordance with a bargain that is satisfactory to labor, capital is often able to derive an advantage at the expense of the workers in industry.

Mr. Young has proposed a method whereby labor can advantage itself equally with the other factors, so that, in a sense, it can say whether it will or will not stay out of the market. It can protect itself and get a fundamentally right bargain, which is the first step toward the fundamental need of the public in relation to industry, namely, to increase production. For with such protection labor has no just grounds for attempting to restrict output.

"I have often felt," said the speaker, "that the measure of our success with the labor problem would be the degree to which we could persuade labor to coöperate in the program of scientific management, which has as its aim, the increase of production. A week ago I was privileged to meet with the presidents of three trade unions to consider a proposal whereby I would be employed to assist in the installation of scientific management in three factories that have for 30 years been in relation with the unions.

"I set up the principle that I would not enter that situation unless the union assented and unless the union would help pay me for the job. The union in question brought in the presidents of two other unions to secure their point of view. I presented the point that hitherto trade unions had opposed scientific management and every other means designed to increase output and that therefore employers who had established relations with trade unions were at a disadvantage in open competition with open shop employers. I presented the point of view, on the other hand, that when the Soviets of Russia took control of industries there, they felt that now that they were in control of industries and were going to reap the benefits of increased output it was up to them to adopt scientific management to increase the output. I said I believed that the unions which the three presidents represented would join in a program for increased output if assured that the gains would be permanent and that the division would be on a permanent basis.

"Those officers unanimously agreed that on that basis they were for scientific management, and that they would employ a firm

[2] Consulting Engineer in Management, 3020 W. Grand Blvd., Detroit, Mich.

of consulting engineers to install scientific management jointly with their employers.

"I mention this incident because it represents an important step forward in the development of scientific management and shows that there is nothing inherent in the philosophy of the workers which restricts output and compels them to limit production to the disadvantage of society, managers and capitalists. The inherent difficulty lies in the fact that capital has the ability to pay off labor and the other factors without labor having an adequate protection of its interest in the bargain."

L. W. WALLACE[1] said that labor problems have always existed and are likely to continue to arise as long as humanity is constituted as it is. He therefore wanted to sound this warning:

"I do not anticipate that at this time or at any future period there will be evolved a panacea that will forever solve any and all problems that may arise between employer and employee. This is no more possible than that a plan can be evolved whereby there will be no more wars between nations. Some form of industrial democracy on the one hand and a league of nations on the other will unquestionably be an agency of great value and influence, but these agencies within themselves will not eliminate labor troubles nor make impossible future wars. In fact, no instrumentality or agency will accomplish much unless there be behind them and disseminated throughout every fiber and thread the spirit of fairness, honesty and justice.

"In all sincerity the principle of the 'Golden Rule' must obtain: do unto your employee as you would have him do unto you. I believe it is the duty of the employer to first demonstrate that he is operating on this principle. It is his responsibility to engender into the minds of the employees perfect confidence, absolute warmheartedness and cordial respect for him.

"It is also my conviction that no man will ever succeed as a leader of men and solve the industrial problems, unless he has a large store of human sympathy in his heart. Unless we are sympathetic, we are cold and indifferent to those matters that are nearest and dearest to men. We are apt to be impatient with human weaknesses, we are apt to make demands that are unfair and unreasonable, and we are apt to be cruel in our decisions and rash in our actions. Unless the principles enunciated are carried out, no satisfactory results will be obtained, whether the plan is a committee system, an industrial democracy system, or a House and Senate plan. The plan or the machinery whereby you are to operate is not nearly so important as the motive that prompts the ideals and the sincerity that obtains."

SAM H. LIBBY[2] stated that they had had a coöperative committee in operation at the Sprague Electric Works since last December. Ninety per cent of the 2000 employees voted to try the plan, which is much like that described by Mr. Young. In the Sprague committee, however, the elected members number about two to the hundred, with chairman, vice-chairman and secretary. Three members were elected to each of six sub-committees and on the sub-committees the management appointed three other members, making six members each. These sub-committees each selected a chairman, which in every case proved to be an appointed representative, showing the confidence of the men in the proposition. Mr. Libby described at length some of the practical workings of the committee, two examples of which follow:

"One of the committees, which we supposed would be the hardest-worked committee, was that on the adjustment of wages and working conditions. Since December that committee has had but 14 cases to review and the last case, No. 14, was the only one during the month of May, and had simply to do with the question of the men ringing out at 12 o'clock noon. They said they didn't think it was necessary that they ring out when they left the works; they were all in, they couldn't get out of the plant without a pass anyway. They presented a very good argument, the committee went over the details, investigated it as thoroughly as possible, and finally decided that the men were right. So what we thought was going to result in a grievance committee, with questions of wages and shorter hours, did not materialize as such.

"Another evidence of confidence was found in the coöperative committee. One month after the committee was started we voluntarily reduced the working day to eight hours and maintained the same weekly pay. We asked for a vote as to what would be done with regard to piece rates, explaining that it would be a large undertaking to go through all the piece rates of the plant in an effort to change them. It was proposed that the piece rates should remain as they were; and when one was found that was not to the advantage of the operator that it come up to the committee in the regular way or that it be adjusted before it reached the committee. The men had enough confidence in the proposition so that they voted 95 per cent in favor of taking the reduced time, the increased day rate, and allow the piece rates to remain exactly as they were."

RICHARD A. FEISS[1], as the result of a discussion introduced by Mr. Young as to the extent to which the question of management is an engineering problem, contended strongly that it is strictly such and that one's views should be big enough to make engineering stand for the things with which the engineer has to deal today rather than for the mere word "engineering" as defined in the old dictionaries. He contended that primarily mechanical engineering is production. The purpose of a machine is to produce and the machine itself must be produced in the process of manufacture. Many times an engineer has seen the best theoretically designed machine go to pieces in the hands of the average workman, because it had been forgotten that a man had to control the machine and its production, and that its successful operation could not be determined solely by the working drawings on which it is based. How, then, can one say that a problem affecting the man whose labor is assisting in production, or perhaps being replaced by a machine which is designed, does not present what is distinctly and directly an engineering problem? Again, we note that the running of two or three machines in a group is much more complicated than the running of one. It must be evident that the questions of the man and the machine cannot be separated and that their relationship is so essential in securing production that the question of labor and its management is distinctly an engineering problem.

H. F. J. PORTER[2] (written). In his admirable paper Mr. Alford gives excerpts from my article in the *Engineering Magazine* for August 1905, which presents a fairly clear idea of my installation of a factory committee in the plant of the Nernst Lamp Company, in Pittsburgh, in the winter of 1903-4, which I understand was the pioneer installation of its kind in this country. In 1905 I presented a paper before The American Society of Mechanical Engineers entitled The Realization of Ideals in Industrial Engineering, in which I referred to the merits inherent in enlisting the interest of the human element regarding matters affecting it in the management of an industrial plant. The basis for this paper was the experience obtained with my shop committee in the Nernst Lamp Company.

When I took charge of that plant it had failed twice and my study of conditions there assured me that one of the reasons for the failures was the autocratic management under which it had suffered. I had for a number of years kept in close touch with several Western plants, particularly the National Cash Register Company, in which welfare work had been carried to a very high degree of perfection, but I never liked the phrase "welfare work" nor the method of application of its principles.

When I took charge at the Nernst plant I decided to install the suggestion system used successfully by the National Cash Register Company, but disliking the method of handling all such features for the management, I determined to have the suggestions passed on first by a committee of the employees themselves and therefore requested the latter to elect by secret ballot a representa-

tive to it from each department. The committee so formed elected its own chairman and secretary and all suggestions were collected from the boxes by the secretary and prepared by him for the committee.

Among the questions considered by the committee were the following:

Wage Payment, the premium system being finally adopted.

Permanency of Employment. The committee considered the taking on and laying off of all employees and succeeded in stabilizing the working organization, developing functions now accorded to an employment manager. As far as I know it was the first time that "labor turnover" was seriously considered. As Mr. Alford states, my ideas on this subject were reported to the Society in the discussion of Mr. M. W. Alexander's paper on A Plan to Provide for a Supply of Skilled Workmen, at the Annual Meeting of the Society in 1907.

Sickness and Accident Prevention, resulting in suggestions for safety and the appointment of a nurse in charge of an emergency hospital and a visiting physician.

Fire Drill. There had been a panic due to a false alarm of fire in the factory before I took charge, which led to the development of a factory fire drill. I found to my surprise after a canvass of representative factories of the country that further than developing a fire-fighting brigade for handling the hose, etc., no such thing as a fire drill existed anywhere. The fire drill at the Nernst plant was the first established anywhere, which at a given signal would take the employees out of a factory building in quick time. A further study of the problem showed that all factories were deficient in exit facilities and when the Ash Building fire occurred in New York in 1911 I was able to bring to the attention of the authorities the necessity for establishing factory fire drills generally, so that laws were passed in New York State making them compulsory and limiting the number of people in a factory to the capacity of the exit facilities, and these laws have since been adopted in practically all the states of the Union.

Mr. Alford refers to the fact that my shop committee was composed of workmen and foremen and that the superintendent presided. The first committee was formed wholly of working men and women, but as they were advanced to positions in the management and the employees reëlected, some of them to office, some foremen were on the committee and the superintendent was made chairman.

The second shop committee which I installed was in the Nelson Valve Company's plant in Philadelphia in 1907. Here we had a shop committee of workers only and an advisory board composed of foremen and the superintendent. I think this arrangement will be found to give the greatest satisfaction.

Mr. Alford mentioned in his paper that it does not seem pertinent to devote space to certain activities that classify under the definition of industrial relations. I feel that he minimizes the importance of some of these features, particularly the suggestion system, benefit associations and pensions, which seem to me to be of as vital importance as profit sharing, methods of wage payment, the safety first movement, employment management, mutual or joint control, etc.

Take, for instance, the suggestion system. It is a factor absolutely vital to the successful operation of a committee system of employees' representation in management, for there is no other means of bringing to the attention of the committee in a satisfactory way grievances or suggestions for improvement, or any other matters which the employees desire to have discussed. All these matters should be put down in writing at the time when they are fresh in the mind of the writer and signed by him. If they are postponed until letters can be written, or if they are left to be verbally transmitted to a sub-committeeman they rarely reach the committee in the way the authors intend, and sometimes not at all, which leads to dissatisfaction.

In the past when the foreman was the autocrat of the shop, the suggestion system was considered by him to be a reflection upon his capability and he worked against it and practically killed it, and it is now seldom heard of. Even the men who have introduced committee systems do not seem to know its value and have not installed it. When properly installed the suggestion system is a wonderful source of improvement in any factory. Many matters which I found had been installed previously by the management and had been dropped as failures were later suggested by the employees, installed and succeeded.

Scientific Management, always difficult to install in a factory under autocratic management, goes in as a matter of course under committee management.

CYRUS MCCORMICK, JR.[1] (written). Employee representation is the first consideration today, because however much emphasis is being placed by workingmen on shorter hours, higher wages, and better working conditions, their underlying motive is really an expressed desire to share in the management of a business as it affects their own interests. Employees and employers are both finding that it is necessary to develop a new foundation for their mutual relations which shall be founded upon something more than a cash basis.

Employee representation is the practical application of the theory of democratic industry, because it permits employees to speak their minds through chosen representatives and to make their collective will effective. The recent war has proved that democracies—however slow they may be to act—are capable of generating a momentum based upon popular sanction which is not to be found in any autocratic system. This momentum is due principally to the good-will resulting from the self-expression which constituents of a democracy are capable of producing. It is the newest application of the old Roman fable of the "bundle of sticks."

I disagree profoundly with Mr. Alford's statement that "students of the present condition of unrest have pointed out that the fundamental is a struggle for control, the opposite forces being the owners and the workers." The idea underlying employee representation is not a question of class struggle, but rather of removing class distinction. It is a constructive endeavor to secure added benefits which are not granted by our present system, rather than a restrictive effort to prevent the spread of ills incident to industrial warfare. It may, it is true, prevent the spread of these ills, but if it can not at the same time ameliorate conditions, it must philosophically be regarded as a failure. The first two principles of employee representation hereinafter described prove these points.

Employee representation must be characterized by one application or another of the following fundamental principles:

1 There must be full representation for employees concerning working conditions, protection of health, safety, wages, hours of labor, recreation, education, and the like. This statement, of course, involves a recognition of the right of collective bargaining. It assumes that the workers, individually and as a group, are intellectually capable of maintaining their share in the joint discussion with chosen representatives of the management.

2 Joint conference between men and management. It is not sufficient to grant the employees merely the right to discuss their own affairs. This discussion must take place with the management or its representatives. If any subject can be brought out into the open where it can be tested by the clash of men's minds and where honest opinions are exchanged in free and frank discussion, a happy solution of any debated point can not be long delayed. The fundamental point is to get together; to talk things over; to debate them; and so to understand each other's opinions and points of view.

3 Shop committees differ only in the basis of representation. The great point is to secure a sufficient representation to build the plan upon an essentially democratic foundation.

4 Employee representation must include an easy channel of approach from the lowest workmen to the highest official in the company whereby the former can appeal to the justice of big minds. In this way it is to be hoped that personality can be reintroduced into industry without depriving industry of the efficiency of broad organization.

5 There must be no discrimination on account of race, sex, political or religious affiliation, or membership in any labor or

[1] Works Manager, International Harvester Co., Chicago, Ill.

other organization. This is an essential tenet of democracy, and if it is not included in the groundwork of any plan of committee representation, that committee can not succeed.

6 Finally, there must be executive supervision for the plan. In this way the experience gained from day to day can be collected and coded into a working principle for the future. The handling of labor problems is becoming the work of specialists, and as the years progress the specialist in labor matters will be more and more important even than he is at present. Quoting from Dr. Thurston, Mr. Alford is not clear as to whether he would set up a special labor department in a corporation or would consider Industrial Relations as merely one of the by-products of an industry. Certainly this is not an engineering problem in the narrow use of the word "engineering," nor is it a problem for psychologists or sociologists. It is rather an attempt to translate humanity into the language of modern industry. The whole problem must be looked at, not merely on ethical, but also on economic grounds, and the future development of Industrial Relations will, it is believed, depend upon a satisfactory solution of this dual view of the problem.

Mack Gordon[1] (written). Although the shop committee and collective bargaining outside of trade-union control are comparatively new and untried methods in management, some conclusions can be drawn from the limited experience at hand.

If the worker does not understand clearly what are the functions of the shop committee, and what his part is to be, it will not have his confidence, which is essential.

How is this confidence to be built up? The management must make up its mind absolutely to turn over to the workers the right of bargaining with it on any matter whatsoever that pertains to the workers' interests, such as:

1 Wages. The quantity to be produced for those wages. The method of determining what the quantity to be produced shall be, such as time study. Individual requests for increase in pay
2 Hours of work
3 Any rules or regulations affecting the conduct of the worker
4 His right to a hearing in case of discharge.

More than five years' experience has proved that the workers are reasonable. As long as there is confidence in the committee and in the honesty of the management, they will remain so. They do not ask for impossible things and when they do it is only because of lack of knowledge as to conditions. A frank and honest discussion will soon dissipate the misunderstanding.

However, the mere existence of a shop committee that can present grievances, ask for increases in pay, changes in hours, review of discharges, etc., is not enough. When the committee finds something wrong and asks that it can be remedied, in the most important cases, the conditions can only be remedied by a change of manufacturing policy, or of methods of management. The management must be willing and able to make these improvements. If it cannot, the mutual confidence that is so necessary will be dissipated, due to the lack of ability to satisfy the workers. It is in this phase of the situation that scientific management can help to solve the problem.

Willard G. Aborn[2] (written). In the first place the employer must be entirely convinced that the employee committees can and shall work out to the mutual benefit of all concerned. Fair-mindedness on the part of the employer and a willingness at the beginning to go more than half way to convince his employees that he is earnestly endeavoring to bring about a mutually beneficial condition is a necessary preliminary to the successful inauguration of such a scheme.

There have been and always will be dissatisfied radical workers in every plant, whose influence increases or decreases in proportion as the fairness of the employer decreases or increases. Therefore, by all means, in instituting these committees, reduce the influence of these radicals by giving the rationals, who are about 80 per cent, entire freedom in the selection of their representatives; in other words, remove all possible suspicion of undue influence at the elections by arranging that they shall be directly under the supervision of the workers themselves or their representatives. Do not permit any official or foreman to in any way dominate, interfere, or even suggest, except as they may be called upon by the workers for advice.

Elections without nominations seem desirable and have worked out extremely successfully where used, in that conservative employees of long service in the plant have almost invariably been elected. Also the time required is much less and result is really more democratic.

Department committees of three are also recommended for the reasons that three are more constructive than one and when representing their own department only have intimate personal knowledge on any subject affecting their constituents.

Welcome joint discussion on any matter pertaining to the plant —in fact, if necessary or desired, originate matters for discussion so that the committees may function and the workers interest in the plant welfare be stimulated. Those who have had dealings with committees know that there is nothing much more dead than a non-working committee. Joint meetings of employer and employees' committee should be held frequently enough to keep up a live interest. Allowing the committeemen to honestly feel that they are originating and inaugurating matters for common good will tend to keep their enthusiasm alive and working.

[1] Consultant, 226 Marion Bldg., Cleveland, Ohio.
[2] 619 West 113th St., New York City.

Guy P. Miller[1] (written). Although the plan of Industrial Relations adopted by the Bridgeport Brass Co. has been in operation only nine months the results have been far greater than anticipated. About 100 meetings of committees have been held during this time, at 25 per cent of which hours and wages have been discussed, and in no case has the conclusion reached been other than unanimous and entirely satisfactory to the employees and the management. Every employee has an opportunity to be heard whenever he has a grievance, which enables the company to adjust little things which cause annoyance and to explain other things to the satisfaction of the men. In order to get the greatest benefit out of these committees, the safety and sanitation work, as well as the work of the sick-benefit association with the insurance features, have been turned over to them. Joint committees are also handling recreational and athletic activities in all plants of the company.

Every three or four months an evening meeting of all the committees is held with a dinner in our cafeteria, and I explain the general condition of the business and ask for expressions from the men, which has helped cement the spirit of confidence which has been established. No plan will be successful which fails to instill confidence, but as soon as the men are confident that the management will give them a square deal they will go half way.

Many feel that agitators may gain control of the committees and organize them as union representatives, but I am convinced that this danger is not to be feared as long as the management has the confidence of the employees, and when this is gone no plan can be successful.

P. J. Reilly[2] in a written discussion emphasized the change in conditions since the time about two decades ago when the general manager of a plant erected buildings, engaged help, bought materials and determined costs. He was unhampered by any restrictions as long as he made profits for his company. Now the old-type general manager would find himself unable personally to cope with the new problems which arise and he must be assisted by a staff of officers, purchasing agents, efficiency engineers, master mechanics and employment managers. He pointed out, however, that such staff services fall pitiably short in their appraisals of the worker and of the job as compared to that which was reached when the owner was present in the shop. This is because many good principles of personal management which are developed by the industrial engineer or the employment manager lose much of their effectiveness because they are applied by foremen who have not been trained for efficient foremanship. In

[1] General Manager, Bridgeport Brass Co., Bridgeport, Conn.
[2] Employment Manager, Dennison Mfg. Co., Framingham, Mass.

many factories the foreman is the only representative of the manager that an employee gets to know well. It is important, therefore, that foremen represent an employer in a creditable manner.

The work of industrial engineers and employment managers must be supplemented by a new type of foreman—one who has been trained for his foremanship. The manager of a large New England factory recently stated, "When the science of human relations is as carefully organized as the science of product and quality of product; when the human relations of the foreman in the large factory unit equal the human relations of the manager of the small shop, the managers will have established their credit as fitting leaders and true spokesmen." Information that will assist foremen to administer their departments more effectively should be organized and presented to them in a form that will make the material readily available. The philosophy behind any rules of organization which foremen are expected to enforce should be explained so that they can enforce such rules without appearing arbitrary. Regular meetings for foremen should be held for the discussion of problems affecting the planning of work, the quality, quantity, and economy of production, the handling of new workers and the promotion of deserving older workers. Such meetings are effective in the enlightenment of foremen so that they are in entire accord with the management's policies in each of these fields. Much can be done in the development of foremen by relieving them from duty in their department for short periods so that they can work under the direction of the employment manager, the industrial engineer, or the master mechanic.

Opportunity should be given to foremen to attend special courses on industrial management, or to visit other factories that they may get the broadening which so many of our foremen badly need.

If the industrial leaders will give them the chance, the foremen will learn to treat help with a degree of human sympathy that will result in better team work. They will develop more patience, judgment and tact, and will eventually realize that men under them will produce best when their heads and hearts are in their work as well as their hands.

D. G. Stanbrough[1] (written). In the last analysis, our difficulties are those of human relations rather than industrial relations, and if we pass from human relations to industrial relations unquestionably some of the specific remedies which Mr. Alford has recommended must be applied. It should be realized, however, that the growth of the factory system does not necessarily mean (*a*) the loss of personal contact; (*b*) the loss of personal knowledge of the work to be done; (*c*) the loss of personal knowledge of the tools and equipment necessary for production, or (*d*) loss due to lack of conservation of effort.

I believe that a wise system of management conserves these relations, and that they will be found to be developed to a higher degree today in many of our industries, than at any time in our industrial history. In fact, I believe that success in meeting present-day conditions prescribes their levelopment, and if this is the case, the natural question is, "How can that development be brought about?" and the answer: "Through education."

With reference to the development of the personal relations, this is a matter of organization. The foreman, in the minds of the workmen, represents the management, and consequently, if we are to be successful in maintaining personal relations, it becomes necessary that we develop a high class of foremanship, and this instruction work must be done by executives familiar with the broad policies of the business and who have had the necessary practical experience to enable them to talk to the foreman from the foreman's viewpoint.

The foreman must be a man of the proper amount of personal kindness and should be able to understand the psychology of management. Such foremen will be found among every class of workers, or at least potential foremen of this caliber, and to develop such men it goes without saying that the factory executive must have the proper viewpoint.

[1] Gen. Supt., Packard Motor Car Co., Detroit, Mich., Mem. Am. Soc. M. E.

I want to take particular issue with the closing paragraphs in the paper. I do not think that we can ever hope for any real measure of success if we are to consider workers in groups or masses. You cannot build morale by appeal to masses. I believe that the appeal must be made to the individual, through the organization line. The spirit of organization can be strongly built up if each individual worker feels that the management is conscious of his efforts and that the appeal is to him personally. Even in a large organization much can be done by the executive in knowing his men. At least he can know a few men in each department, and through them the spirit can be communicated to the organization.

John L. Henning[1] (written). During the past five years hundreds of thousands of potential business men have been added to our population and practically no new unorganized labor has been added to our supply with which to carry on the work created by this additional ambitious army of business makers.

There is every indication that immigration will be practically stopped for the next four or five years, perhaps longer, and an entirely new situation will be presented: viz., the machinery already in existence supplemented by additional but limited output will be called upon to operate much more continuously (and therefore efficiently) than ever before.

Even with greatly increased efficiency there will not be enough labor to meet requirements, and this is where the engineer will come into action. It is strictly up to him to create new machines and new methods of utilizing old machines to accomplish the required result with whatever labor is available.

With the door closed to disorganized labor from Europe, we will soon become really American and instead of being apprehensive about higher wages, I believe all real Americans will soon be proud of the wages and standard of living afforded our workers in this country.

Those classes which have been rather thoroughly organized for a number of years are doing very well, but there are a large number of classes, such as clerks, stenographers, and responsible employees of banks and industrial institutions that are having great difficulty in providing only the real necessities of life. Many engineers are among the classes that are having trouble in making both ends meet. Large industries cannot do anything that will help them through their present and future difficulties as much as to recognize the wonderful opportunity of the engineer and *voluntarily* place more responsibility on him, at the same time not forgetting to make him comfortable.

As Mr. Alford states, the loss of personal contact is one of the contributing causes of present unrest; but if employers will use the engineer to the fullest extent and permit him to take some responsibility in handling labor questions he will, I believe, demonstrate that his so-called fault of dealing with labor from an individualistic viewpoint may be turned to a very good account. He will use a little more human sympathy in dealing with labor, which after all is simply a collection of human beings who inherently have the same "rights, needs and aspirations" as the employer and those dependent upon their product of industry.

Referring to Mr. Alford's conclusions as to the reasons for the apparent failure of remedies heretofore applied, I have proved to my own satisfaction, in a small way, that reasonable assurance of a permanent job is the greatest single weapon against unrest and Bolshevism. The moment uncertainty as to tenure of job and rates of pay is introduced into a workman's mind he is ready to believe almost anything, and you cannot expect a worker in any class to save for a home when he has none or only small assurances of the regularity and permanency of his work.

William M. Leiserson[2] wrote saying that the tendency of the engineers is to consider workers only as individuals, while the "industrial psychologist" holds that they must be dealt with in the mass. On the other hand, the economist, who has been studying labor problems and industrial relations for more than a hun-

[1] Consulting Engineer, 525 Kirby St., Lake Charles, La. Mem. Am. Soc. M. E.

[2] Working Conditions Service, U. S. Dept. of Labor, Washington, D. C.

dred years, takes a broader view based on a study of the labor problem, its history, and its causes and manifestations under different systems of industry.

The economist, he continued, analyzes industrial relations and finds not one problem requiring individualistic or collective handling, but two sets of problems, one requiring dealing with each worker as an individual, the other necessitating dealing with wage-earners as a class. The first of these may be called the personal relations in industry, the second, the economic or governmental relations. The personal relations include such subjects as recruiting, selecting, hiring, training, placing and promoting workers, looking after their health, safety, comfort and welfare. These problems require individual problems or they are technical questions that must be decided by technical experts like the engineer or the physician. The second set of relations, however, have to do with bargaining, wages, hours, shop government and discipline. These questions are essentially controversial. They cannot be decided by technical experts. They are matters of opinion requiring decision by a democratic majority.

Failing to catch the economist's fundamental analysis of the problem, engineers, employment experts and industrial managers are wont to group all industrial relations together and to include the fixing of just rates of pay in the managers' function. Accurate records of individual production and fairness and square dealing with employees, they think, will assure justice to the workers. This may be true as far as injustices between individuals within a plant are concerned under a general scale of remuneration that is already fixed, but it overlooks entirely what President Wilson has called the progressive improvement in the condition of the wage earner, the raising of the scale of all so that labor may receive a very much larger share of the product of industry than it gets today.

The other day the waiters of the city of Toledo adopted a scale of wages and presented it to the hotels of the city, saying, in effect, "This is what we consider it fair and just to charge you for our labor," and they resented it when one of the employers did not want to pay them what they thought they were worth. They say, "Why should management place the price on labor? It does not set the price on the materials and machinery it buys, why should it on the labor? Why should not the workers set their own price? They know best what it costs to live and to produce the energy we call labor."

Yet from the national point of view neither the one side nor the other ought to be permitted to fix the scale of wages, according to its own ideas of what constitutes a square deal. The national welfare requires that it be set by negotiation and bargaining and mutual compromises and concessions, which cannot be done without the right of employees to bargain collectively with their employers.

H. L. Gardner[1] wrote outlining in detail the personal qualifications of the employment manager, his duties and the functions of the employment department. He said that the manager should be a broad-gage man, preferably a high executive or an officer of the concern, for which he preferred the title "service manager." He should be of sufficiently large caliber to "sit in" with the officers or a committee responsible for all relations between employer and employee; and being thus constantly apprised of general problems and accepted policies he can then organize and direct his department to coördinate with all other service departments and activities.

Interviewing is perhaps the keynote of his work, and with the right viewpoint and with practical knowledge of plant operations and conditions he can be of tremendous influence in building the right kind of working force. Continuing, Mr. Gardner wrote:

"One of the more abstract functions of Employment Management deserves detailed attention. If we are to offer a satisfactory substitute for the decreased personal contact in industry, the foremen are the channels through which we must work. To the workmen, the foremen are the personification of the manager and the company; it seems vital that such representation should harmonize with the general policies of the concern, yet too little has been done to develop this contact and to insure the desired results. To my mind, one of the most important services which employment management can render, and one which has a most important influence on industrial relations, lies in securing real coöperation of foremen through understanding of, and sympathy with employment methods of attack on the common problems of personnel and production. This may sound too theoretical, but it is, in fact, a tangible problem, and quite possible of surprisingly satisfactory solution.

"At the risk of repeating certain thoughts which I emphasized at the National Association of Employment Managers Convention in Cleveland, I would criticize the average employment department as too selfish. We too frequently devise theoretical solutions for the existing problems and impose them on the plant without sufficient sympathy for the other fellow's opinions and troubles. Complete success demands that the employment department thoroughly acquire the general plant viewpoint and merge its individual activities into the broader service program.

"Several vital changes in the status of employment management have taken place in recent months. War pressure for 'quantity production' has been relieved and the opportunity for intensive personnel work is much brighter. Changing social and economic conditions are making more important the necessity for the right relationships, and, to use Mr. Alford's words, focusing attention on the 'interacting human rights, needs and aspirations in productive industry.'"

[1] Manager Personal Relations Sec., E. I. DuPont de Nemours Co., Wilmington, Del.

Mark M. Jones[1] (written). Functions in industry can be arranged according to many very interesting classifications. The five M's—men, money, methods, materials and machines—have appealed to me as a simple classification. Engineers will recognize that in our progress on the fifth M—men, we have from an administrative standpoint reached a point of about 30 in case we consider progress on the other four M's—money, methods, materials, and machines, as being at 70, with 100 the ideal.

Employment management as a part of Industrial Relations has as its object the administration of recruiting, selecting, placing, transferring, promoting, and releasing workers on an engineering basis. It seeks to apply the labor policy of the enterprise so far as it may affect those functions named. Its effectiveness is only limited by the strength of the belief of the management in the value and possibilities of such a service.

Employment management is distinctly a "service" function. It is an aid to production and a department for the purpose must always be operated with the proper understanding of the important part it plays in turning out the finished product.

A well-organized employment department surrounds the initial contact of the worker with those activities which influence him favorably and contribute definitely toward the final object of production. It provides a proper reception place and courteous treatment while the applicant is being studied. It studies him from mental, moral, physical, financial and social standpoints with the object of placing him where he can work to his own best interests. The employment manager knows definitely that an individual cannot work to the best interests of the enterprise unless he is working to his own best interests. The interests of worker and business are identical. From the standpoint of placement there is no divergence. From the standpoint of effectiveness, however, men must be weighed more carefully and a more exact method of so doing remains to be developed.

The whole field is rich in opportunities for pioneering work. During the coming months and years there must be worked out and applied:

More exact methods for measuring men
Better coördination of personnel and production functions
More definite methods for recording meritorious services
More exact methods of promoting workers
A more careful observance of the relationship between cost of living and wages paid
Provisions for care during old age and sickness.

[1] Director of Personnel, Thomas A. Edison Industries, Orange, N. J.

There are also many other problems, each step in which creates more problems in the great game of employing large numbers of men as intelligently in our great organizations as would be the case if but 40 or 50 men were the total number.

If during the coming months engineers will have in mind just one need of this field, namely, the same recognition and study of the fifth M—Men—as of the other factors in production, they can do much in assisting American industry toward the great ideal of industrial nations, which is that of "increasing individual production."

Mr. Alford's Status of Industrial Relations is a timely summary of past and present, full of valuable data and epitomized in a warning to be heeded.

Harrington Emerson[1] (written). I have been requested to contribute to the discussion by notes on Wage-Payment Plans as one of the problems of modern industry.

Wages are but a phase of a much deeper problem. What is the starting point? I paid a man recently $10 for a half hour's work and I received an equivalent in return. When in Alaska I paid day laborers $15 a day and felt lucky to find the workers. I have personally worked for $0.10 for a long day's work and was grateful for the opportunity.

On the one side are the necessities of life: to live morally, to have health, time to study, time for industrial improvement, and to have opportunity; on the other, what the earnings will afford, and again also the market rate for similar services. An empirical equilibrium is struck. Not as high wages as an ideal life would require, but often more than the earnings justify.

But what I recognize is that three conditions enter into work and wages: (1) The basic hourly wage, however determined; (2) the equivalent in output for the hourly wage; and (3) the special excellence of the worker. Of these the third, the individual excellence of the worker, is the most important.

The great truth, as yet only partially recognized, is that the superior worker is worth so much more than the average or inferior worker that any amount of care and supervision and all the extra pay required to secure him is a good and paying investment.

From this conviction it is evident that I am wholly out of sympathy with so-called profit-sharing, which repudiates individuality and makes of business a kind of providence that rains on the just and the unjust alike.

There is no connection between profit and skill and effort. The product of the highest skill may be sold at a loss, the product of malingerers may be sold at high profit.

The extra wage paid for individual competence is not a dole, a gratuity, a present. It should be a measured and full equitable compensation for a measured delivery.

There are current wages so low as to be dishonest. There are also current wages so high as to be dishonest.

Starting with a basic hourly rate, increased yield should command higher pay as long as unit costs drop. An increase in wages that increases unit costs (unless money is falling in value) is robbing the three other divisions of the community.

The problem always is to so lower costs as to increase output, to lower unit costs yet to pay more per hour, to give greater security and volume of investment yet to lower interest and dividend rates, to so compensate executives as to stimulate them to secure the best combinations of men, materials and machines, thus again lowering unit costs and adding to the common fund.

Out of the common gain from reduced unit costs only four classes can make a gain:

1 The buyers, who are entitled to a permanently lower price if they continuously buy either more or more regularly or in standardized form
2 The provider of equipment, whose temporary risk must be temporarily covered not only by interest but by insurance against loss
3 The worker, whose only claim to higher compensation rests on a reduction in labor unit costs
4 The administrator, organizer, inventor, man of original and creative personality, who is entitled to the worm the early bird catches.

Fundamentals, not expedients, underlie all real solutions of the wage problem.

[1] Director, The Emerson Engineers, 30 Church St., New York City.

R. G. A. Phillips[1] (written) To my mind industrial relations problems came into being along with the "Big Business" idea and I think it well and timely that we give these various problems serious thought and study.

In our industrial relations work at the works of the American Multigraph Company the biggest topic of the day is our industrial democracy. Therefore, although it comes last in point of things done, it ranks first in order of importance.

In our case Industrial Democracy was no "spur-of-the-moment idea." It is a subject we have been studying almost as long as we have been in business. Our active interest dates back about five years—we have been all that time progressing toward our goal. It took about a year and a half of constant study before the final plan with its constitution became a fact. It took definite shape toward the end of February, 1919, and finally on March 1 the plan was put up to the employees.

The plan of putting it up was interesting—I don't recall having heard of it being done our way before. We mailed a letter, over President Osborn's signature, enclosed with it a book describing the plan and the constitution, and sent it all to the employees' home addresses. The letters were so timed in the mailing that they should reach the homes Saturday morning. We wanted them to be part of the Sunday reading program, and had a "hunch" that they would also be part of the Sunday conversation program. We figured that the more a person had to talk about the plan, the more thorough would be his understanding. We also figured that inasmuch as the envelopes bore the return card of the American Multigraph Company, by the time Mr. Man got home there would have been quite a bit of curiosity aroused. We figured strongly on the question, "John, there's a letter come for you from the company—what are they writing to you about?" Later developments proved that we were right in our judgment.

Along with the letter went a pledge card. The employees were asked in the letter to read the plan over; talk it over, and come in the following Monday to President Osborn's office and tell him frankly what they thought of the idea. If they liked it and were in favor of it they were asked to sign the pledge card. If they were not in favor of it or distrusted it they were asked to tell Mr. Osborn what they thought and he tried to "sell" them on the real purpose of the plan.

About 95 per cent of the people accepted the plan with the greatest enthusiasm. About one per cent prophesied dire failure. About four per cent thought it was some sort of a trick. This last class was most amusing. Its members admitted that so far as they knew the company had never gone back on its word to the men. It had never played any tricks on them, had always been square and all that—and then they would hesitate, and the silence would speak volumes for the broken pledges that had made up their experiences before they came to us. I don't blame men for being suspicious. Some of the stories we have heard would break the faith of the strongest of us. There must be no more of it. A square deal must be what it says.

Perhaps, in telling of the steps leading up to our installation of Industrial Democracy, it may be thought I am laying too much stress upon a detail. I am not. The success of the whole plan depends upon the introductory steps.

Well, we had our elections—lots of competition between rival candidates; lots of campaign speeches; lots of real old-time election enthusiasm—even one case of election fraud! Immediately upon taking office the congress turned its attention to that one case of election fraud, with the result that those concerned were eliminated,—three of them. That bit of serious-minded justice was startling, a true index of the seriousness with which the men took their new jobs.

Since then we have had many incidents that have made us wish

[1] Vice-President, The American Multigraph Co., Cleveland, Ohio.

we had started sooner. For instance, I will refer to some of the minutes of the congress meetings and pick out suggestions that were approved by the senate as being wise and necessary.

Educational Committee: Suggestion that certain employees be taught what the Multigraph does so they might do their work with greater understanding. (Assemblers and final inspectors)

Production Control Committee: Suggested rearrangements of departments that will produce greater results

Suggestion Committee: Presented about fifty new ideas, the principal one of which will result in considerable saving in handling of tools, etc.

Sales Coöperation Committee: Working all the time with Sales Department. Pushing manufacturing and keeping up standards. Latest job the reduction of time taken to fill and ship foreign orders about 80 per cent

Sanitation and Safety Committee: Always at work. Producing great results. Total suggestions adopted to date, about 65

Recreation Committee: Managed several dances, an indoor baseball league, bowling league and all gymnasium classes

Spoiled-Work Committee: Very active. Reported last week on correcting a condition that reduced scrap and increased production on a certain part about 150 per cent

Shop Training: Manages all class work during season just finished. Promoted mathematics classes (two each week after hours) and a big general shop efficiency class that met every Friday night, having an average attendance of 150.

Industry has got to begin to get all the effort it is buying. It should no longer be satisfied with the services of the hands of its workers—the brains, too, must be induced to participate. This matter of brain and hand cannot be commanded either—it must be more of a pull-together effort. We think we are headed that way through our Industrial Democracy.

C. B. Auel[1] (written). Both capital and labor have within their ranks elements of sufficiently radical tendencies and proportions to cover them at times with opprobrium in the estimation of the public at large, and it is these two elements, which might be termed the arrogant and the ignorant, in their own midst, that each must get rid of, if they are to make the most headway in their common progress.

It seems almost certain that the six lines of development listed by Mr. Alford will go a long way, if fairly universally adopted, toward lessening industrial unrest; but, they will hardly eliminate it since the fundamental cause for this unrest as admitted by the author is fear of unemployment, and methods of overcoming it have not been included. Some persons may point out in opposition to this statement that during the recent period of tremendous industrial activity, labor unrest was perhaps at a maximum; but, in answer to this it may be said this unrest was quite abnormal, due very largely to war conditions, and was moreover aggravated by employers practically bidding against one another in the labor market, with the very natural consequence that labor tended to oscillate to and fro, wherever wages were highest, or in the contrary event to insist on wages being brought to the high level.

One very important item the author has omitted from his list is "Americanization," which has been carried on by many corporations for a number of years past, principally through the medium of schools for their employees; but, fine as is the work already done by them, the task is so huge that it needs to be supplemented by greater efforts on the part of the various states if real headway is to be made. In Pennsylvania, for example, one authority has announced that with a population of 8,000,000, there are 1,500,000 foreigners over the age of 10 years and of these half a million cannot read or write English, while a third of a million cannot read or write any language, but what is worse than these statements is the further fact that the half-million that cannot read or write English increased to this figure from a quarter-million in the short space of 10 years. Illiteracy is a fertile field for the propagation of every kind of "ism" and it seems astonishing that a condition like this should exist in any state in our Union, and doubtless a similar situation exists in certain other states.

[1] Director of Standards, Processes and Materials, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa. Mem. Am. Soc. M. E.

Dwight T. Farnham[1] (written). At the close of the paper Mr. Alford opens a question whose just solution will, I believe, within the next ten years tax to the utmost the ability and resourcefulness of our financial, economic, ethical and engineering minds. The fact that the International Harvester Company had hardly installed their "industrial democracy" plan before they were deluged with recommendations for rate raises illustrates this trend. When their committeemen, however, were taken to the company's books and shown that the business could not continue if their demands were granted, unreasonable demands for the most part ceased. From the standpoint of human relations, then, the first general principle necessary in order to establish a sincere industrial democracy would seem to be the possession of profits which will survive the light of public opinion.

The fair division of the rewards is the question which we face, and it will call for the development of the general principles under which controversies may be adjudicated. The first step is perhaps the establishment of a fair return upon capital which is so invested as to be reasonably secure. The next step in logical order to insure stability would then be the determination of adequate sinking funds to make reasonably certain steady dividends from each sort of business. Setting up such reserves would take investment in industrials out of the gambling class and would make them attractive at a 6 or 7 per cent return instead of having to offer chances of 15 to 20 per cent in order to sell stock.

One of the rocks upon which profit sharing has in the past gone to pieces has been its call upon the workers to share in the sacrifice during dividendless periods. The other has been the determination of the share to which labor is entitled. The solution of such questions requires first the scientific analysis which the engineering mind is best qualified to make.

What Mr. Alford describes as the second great tendency in the development of industrial relations,—the willingness to consider the workers in groups—I interpret as not so much a plea for an understanding of mass psychology as a plea for that knowledge which brought the ancient Greeks to the belief that he who understood life was all-powerful. Every age has had its interpreter of motives which actuate humanity. Today the human psychologist is an industrial psychologist. We applied the mind of the engineer first to materials, then to machines. Now we have reached labor.

C. E. Knoeppel[2] (written). Through organization and specialization in industry, relationships have each year become more and more complex, so that today this great problem of human contact is by far the most important confronting us, and my prediction is that from now on Industrial Relations will be considered the keystone of the industrial structure.

I am therefore pleased indeed to see that The American Society of Mechanical Engineers is giving this matter of Industrial Relations the prominent place it occupies. If the engineering world does not give the subject attention, where will the initiative come from? From the workers? No. From the employers? No. I say "no" in both cases advisedly, because in the last analysis each side is generally suspicious of the other's motives when suggesting improvements having to do with human relationships.

The world-wide tendency toward socialism and revolution in ideas, if not in acts, is due not so much to desire for political changes as to a demand for economic changes. What the great masses of people want are homes, food, farms, clothes, jobs, wages which balance cost of living, participation, representation in affairs, opportunity for self-expression and development.

The gigantic convulsion the world is now going through seems to me to be a protest against the way modern society is organized, against much in the present plan of man-to-man contact. The purpose of the coming era, as I see it, is to find the right basis, and this the people the world over will do, regardless of the strife and bloodshed necessary to its accomplishment.

Industrial Personnel Relations

By Arthur H. Young[1], Chicago, Ill.

The present focusing of attention on personnel relations, I think, will result in a new era in industry—as much an epochal change as we have had through various fundamental causes heretofore; such as the change from the original craftmanship to larger shop organization, made possible by power development, power transmission, changes wrought by methods of communication, and refinement of the methods of transportation, the era of consolidation of interests, and so on, and one has to stop and wonder why at last we have come to the consideration of the human factor.

We have probably had as great a refinement as would produce any revolutionary changes in machinery and methods and practices in everything except that relating to the human factor. All of us here have witnessed the birth and the growth and the final development of the safety movement, and more recently, too, employment management.

I refer to those, particularly, as factors in personnel relations of today, and illustrating how rapidly changes are coming about. I think it was only back in 1906 that the first organized effort in safety was made. It is generally credited to the South Chicago plant of the Illinois Steel Company, under the leadership of Mr. R. J. Young. He was a sort of genius who suddenly discovered that accidents were preventable—that it was no longer necessary to kill and maim men as a part of the making of steel.

Development of the Safety Movement

At first not much attention was paid to his proposition, but it rapidly gained support, due to its humanitarian appeal, its evangelical aspect. The first attack was naturally very largely along mechanical lines—the removal of projecting set screws and other parts of revolving machinery, the railing of platforms, the guarding of gears, changes in construction, marking of aisle spaces, and all such things.

A very disappointing result was had, because at the end of two or three years, after several hundred thousand dollars had been spent, at that particular plant accidents had not been reduced over 20 per cent, and generally speaking, today safety engineers rate the mechanical factor or the correction of engineering practices as not contributing more than 20 per cent to the possible efficiency of the safety movement.

It was immediately discovered that the real problem was psychologically to teach a naturally careless man to become habitually careful, and that more than 75 per cent of our accidents were preventable by a correction of habits of thought—of thinking safety all the time. To illustrate: It is perfectly natural to cross a street just exactly as a chicken does—to look neither to the right nor the left, but step right out from the curb; and it is only by a process of education that we learn to pause at the curb and look up and down the street and then walk into the middle of the street and then glance again, and finally to cross the street. That is a process of education which will prevent accidents, and it was what was immediately arrived at in industrial safety engineering.

The shaping up of that problem brought its immediate solution, and brought into play a most interesting development from the laboratory of safety engineers. We had movies, bulletin boards, mass meetings, and finally the formation of public safety councils, the introduction of the study of safety in the schools. Its serious considerations by civic police departments and other parts of society is really the product of the industrial safety engineer, because he realized that in order to make a man think safety all the time it was necessary to work on him not only while he was in the shop, but at home as well. And he carried his message to the man in the shop through his children whom he encountered at school, and during the hours that he was walking to and from the plant or riding to and from the plant by public safety bulletins and so had a continuous propaganda working 24 hours a day in order to make him think safety.

Immediate results were achieved. Taking again, for example, the South Chicago plant of the Illinois Steel Company, with which I happen to be familiar, back in 1906 the frequency of fatal accidents in that plant was 47 during the year, or about one a week. By 1913 that rate had dropped to 7, and it has since stayed at about that figure.

As in fatal accidents, so in the less serious accidents, the frequency rate dropped in the same proportion; and in the Illinois Steel Company there has been a reduction in the frequency of accidents to employees on duty of over 85 per cent since the 1906 rate. That was duplicated in nearly every plant of the United States Steel Corporation, and in thousands of other industrial concerns as well.

There have been a number of by-product results which have directly contributed to the growth of personnel movements and industrial relations, as we term them today, growing out of this safety movement. In the first place, it was found that not only did this human interest conserve lives, but that it was a paying proposition; originally it was an interest in the cause of humanitarian principles, and safety was regarded as somewhat of a fad by a great many employers.

After a sufficient period of experience on which to establish definite figures, it was found that safety was really "good business." The Steel Corporation has published the most interesting figures along this line, showing a net saving almost exactly equal to the cost of the safety work, or 100 per cent on the investment.

There is a striking unanimity in the form of organization for efficient safety work. The original movement in 1906 resulted in the formation of shop committees; as soon as it was realized that the problem was one of education of the workman and that his interest must be aroused, means were sought to turn the problem over directly to him, and I believe the first safety committees were organized at the South Chicago plant of the Illinois Steel Company.

Shop committees—the workmen themselves—were given charge of the safety work. It was their duty to investigate the cause of each accident, fix its responsibility, and make recommendations for a prevention of its recurrence. In addition, they were to make regular inspections of the plants, and by their foresight, and recommendations were to prevent, as far as possible, the recurrence of accidents.

That form, possibly modified, is almost unanimously used by safety workers today in all industrial establishments of any size—some form of a shop committee. It may be of the workmen themselves, it may be workmen in one committee reporting also to a committee of foremen, or it may be a joint committee, or it may be a joint committee of workmen, foremen and officers of the company, but the successful safety program of today includes shop committees.

In addition to the definite return on a cash basis of the safety work, there have been several interesting by-products. The first is the reduction of labor turnover. The Steel Corporation's reports recently published, show that since 1906 they prevented, roughly, 25,000 fatal or serious accidents. They rate as serious any accident which disables a man more than 35 days, or results in a permanent disability, such as the loss of a thumb, or an eye, or other member of the body.

Now, it is reasonable to assume that such an injury would require the replacement of the trained worker, and Captain

[1] Manager, Industrial Relations Department, International Harvester Company.

Address, slightly condensed, delivered at the Industrial Relations Session of the Spring Meeting, Detroit, Mich., June 17, 1919, of The American Society of Mechanical Engineers.

Fisher and other writers on the subject have given us some interesting figures as to the cost of replacement of trained workers. They vary anywhere from $10 to $200, depending somewhat on the way it is figured, and somewhat on the worker. Of course it is a fair statement to say that steel-mill workers are fairly well trained, and probably $100 as the cost of replacing a trained man with an inexperienced man is not an over-estimate.

If we multiply 25,000 prevented replacements of trained workers, because of the efficiency of a safety movement, by $100, we have a neat little by-product, due to reduced labor turnover through efficient safety work.

And then, too, there was another manifestation. As is generally known, the Steel Corporation has been facing a suit for dismemberment. While the hearings were on several years ago there appeared voluntarily a number of old employees who petitioned that the corporation be not dissolved, because that would mean a return to the days of ruthless competition when they did not have standardized safety programs. Of course, no one knows what effect that action had on the decision, but it presented concrete evidence of the boosting of the morale of the workers through safety work.

The Question of Employment Management

Turning for a moment to employment management, and asking your pardon for a bit of personal reference to illustrate exactly what has been the change in employment methods, I will cite the circumstances of my first employment. I went to work in a steel mill during vacation time when I was thirteen years old. I reported to the engineer and he turned me over to his assistant. The assistant said, "Do you know anything about oiling?" I have said that I was thirteen years old; naturally I knew everything about anything. He said, "All right, here is the cylinder oil, and there is the beeswax and some sand. Here is a ladder. Go to it!" And that was the extent of my instruction in oiling.

The third day I was on the job we had a fire caused by an overheated bearing. I discovered the fire when it first started, threw a bucket of sand on it, and put it out, and by the time the boss got there I had the oil cup in securely, had it full of oil, and was working away with a wire. I told him the oil cup was plugged up. I got away with it. (Laughter.) Quick thinking once in a while will save you your job, you know.

The day following the State Factory Inspector came through and asked me my age. I told him I would be fourteen the next December, and he said "There is a state law that says no one shall be employed until he is fourteen," so I had my first experience of being fired. But I still have distinctly a feeling of horror as I think of the days that I climbed on a rickety ladder, unsafe as unsafe could be, up to a high-speed shaft. In those days we oiled while the machinery was in motion, and the high-speed pulley on one side of me without any protection whatsoever, and couplings and collars on the shaft, had projecting set screws and bolts galore. There was absolutely no thought given to safety.

I well remember the first day I was on the job. An emery-wheel explosion occurred. It was frequent in those days, just as frequent as crane runway accidents were, and those things that you don't hear of any more.

And I also think of the possibility of a great financial loss through the neglect properly to educate a new man in a rather important and dangerous job. If that fire hadn't been discovered within the first five minutes it would have swept through the shop.

Procedure of a Present-Day Employment Manager

Contrast that with the employment program in effect in many shops today. In every well-managed institution there is an employment manager, not necessarily known by that title, but functioning as such anyhow, to whom a request to fill the vacancy of oiler would be referred. In my own case my reception at the gate was somewhat individual, because my father was employed at the plant, but if there had been a vacancy, and no one who was known personally was available, the assistant engineer would have gone to the gate and picked a man from the waiting crowd, and a crook of a finger would have put that fellow on the pay roll. The paymaster would have been informed that this man was oiling.

Today there would be a process of selection. Instead of the group hanging around at the gate, there would be a well furnished employment office with a waiting room, and when the request for an oiler was received by the employment manager, he would go out and seek a man who had some experience or who was adaptable for that position, and he would also know in full the duties and just what specifications he would have to meet in getting the right man for that job.

If the man whom he chose were a foreigner that man would be interviewed across a desk by a man who could talk in his own language, and be invited to tell in full his past experience. If he lied about it, that would show up in the replies to the letters of investigation that are sent out as a rule.

I am not one of those who believe that the employment manager is the final judge of the fitness of a man for the job, I think that rests wholly in his performance on the job, and the foreman is probably the final judge there, but certainly the employment manager can by intelligent first sifting, by coarse sifting, get rid of many palpably undesirable applicants. The applicant who seems after that sifting to be the man for the position would then be given a complete physical examination, not necessarily to reject him if physically impaired, but to make sure that he would not be assigned to a job that would further injure him if he had any physical disability.

If he were acceptable after that physical examination he would probably be told something of the policies of the company; be given an introduction to his employer—the corporation—and be told of its safety program and handed a book of rules of conduct. He would probably be told that this rule book was made up by the Safety Committee, employees in the shop, and that if he didn't fully understand it and wanted to quiz anybody on it he had only to seek the nearest old-timer who had been concerned in the revision of the book, and he would be given full and complete information. Undoubtedly, he would have greater respect for the rules when he learned that they were made by the men themselves.

Then he would be told of the promotional opportunities,—that it was the policy of the company to promote from the ranks, not to hire anybody at a given wage unless they were satisfied that nobody then in their employ at a lower wage could be promoted to fill that vacancy. He would be quizzed particularly as to his ambition. What did he want to be? He would not necessarily be put upon the job as an oiler permanently, but in an efficient filing system for recording applications his ambition would be registered. If he aspired to be a machinist and had stated that he had had certain experience as a bench hand and was attending night school, that would be recorded; and later, when a machinist was desired, preference would be given those applications from employees already in the service. Probably at that time the employment manager would send for this chap and say to him, "When you first went to work here six months ago you were put on as oiler. I understand you are still doing it, and you said you were going to night school to learn to read blueprints and take up manual training, and so on. Just how proficient are you as a machinist? Now I have a vacancy and you might be of use." And possibly he would be fitted into that job.

When he was hired there would be entered on his employee's record card a pretty complete history of him, his social condition, whether married or single, how many children he had, just how many dependents he had, where he was born, his age, his schooling, his military service, if any, whom to notify in case of sickness, result of physical examination and so on, for statistical purposes and then he would be sent to the job on sort of a personally conducted tour. He would be taken by an agent of the employment office, watchman, or special guide, and first shown the gate nearest his work so that any unnecessary hazard of

traveling through a long plant might be avoided in coming to work.

In the meantime, if he were a single man he would be assisted in getting a proper boarding house. If he were a married man, temporarily located in a boarding house, the employment agency would probably show him a map of the vicinity of the plant and the desirable residential districts for his type, and give him a list of reputable real estate men as an assistance to him in locating permanently, and show him the street-car lines whereby he might best get to work. Finally, when delivered to the foreman for whom he was to work, he would be introduced by his own name and learn the name of his foreman. Nowadays, the worker, whether he be foreigner or American born, is introduced to his foreman by name and the guide makes sure that they understand each other.

The foreman probably repeats "John Sobrinski—did I get it right? Well, my name is John Smith. I am your foreman." And the last word of the personal guide is, "The labor supervisor particularly requests you, Mr. Foreman, to give this man any special introductions necessary in the particular hazards of his job." And then and there the foreman, either himself or through a fellow-workman, tells this man something about his job, and introduces him by name also to one or two of his neighboring workmen, so they will know each other, and the man can go to his fellow-workmen and seek and get information.

I know all of us here have probably been on a new job at least once in our lives, and I don't care how brazen we may have appeared then or how brazen the foreign workman or laborer may appear when he first goes on the job, yet down in his heart there is a certain shyness and a certain craving for fellowship, a desire to have somebody that he may know by name, that he could go and ask a few questions of. This feeling exists just as much in the heart of the laborer, be he foreign or American born, as it did in our hearts when we went to work in a strange place.

Some employment agents go still further, and during the process of hiring a worker give him a movie show picturing the complete operation of the plant—taking it from the receipt of the raw material, through the various manufacturing processes, on through shipping, just as general as it may be or just as complete as it may be in the space of time available, and increasingly that time available is lengthening.

We used to brag in employment management about hiring a man in a minute, or half a minute, or in a number of seconds, or about the number we could put to work in a year. But that has changed; now we are beginning to boast of taking an hour and a half, and even a week and a half to put a man properly on his job.

Now, it doesn't need anything more than an appreciation of that contrast to bring to your mind how well sold a man may be on his job, how much he may be made to feel that he is a constructive part of that establishment, if he is put to work by the modern method, as contrasted with the former. If when he is put on the job the foreman calls his attention to the movie pictures of the particular operation that he is engaged in, and if it only be wheeling cinders away from the central boiler plant—if he is told at the time that that is the central boiler plant that furnishes the power to run the plant that does the things that he saw in the movies and that these cinders are the refuse from the boiler that generates all that power—then and there he links himself to the plant as a constructive force, as an important part of that machine, and that is very necessary if we are going to settle this unrest that we now feel.

The unrest in industry today is evidence of a social, a political unrest that must be met freely and frankly and squarely and corrected. In fact, it is manifested as Bolshevism in its ultra-radical form. It is no less than that. Probably when the history of the Bolshevik movement in Russia is finally written, and we know just what its causes were, it may be found that a large contributing cause was the fact that the citizens of that country had no part whatever in their government. Things were done *at* them and *for* them, but never *by* them. They were never taken "in on the know."

And while it is possible that their condition as citizens of that country under despotism was as good, their living conditions and all other conditions just as fine as they themselves might have done through democracy, they never had that feeling because they had not been consulted. It is simply a statement of basic psychology to say that we are only mildly interested in the things that other people are doing for us, but we are intensely interested in the things that we are doing for ourselves.

Going just a little further, if we have seen, as in the safety movement, the efficiency that may be gained through consulting the workmen themselves on such a matter of common interest, isn't it perfectly logical to go to the men themselves for consultation on other problems of mutual interest—recreation, sanitation, health, and then the controversial matters of hours and wages?

It has been stated by Professor Hoxie that naturally the aims and purposes of employee and employer are antagonistic; that the employer seeks long hours and low wages as a means to a low cost of output, and that conversely the employee is constantly seeking shorter hours and higher wages, which must necessarily mean a decreased output.

There is abundant experience in the industrial world today to show that the reduction from twelve hours to ten hours in the length of time employees are working has not decreased production—that the reduction from ten to eight hours has been accomplished in factories without any decrease in the output, and that today reductions are being made from nine to eight hours without any decrease in the output. Shorter hours do not necessarily mean reduced output. Neither do higher wages necessarily mean increased cost, if they mean a higher standard of living, a better mental and physical development. I firmly believe that there is a common ground upon which employer and employee can meet for the consideration of their problem, and it need not be a controversial affair either in the consideration of wages and hours any more than any consideration of safety or health or recreation or plant canteens or anything of the kind.

The International Harvester Company's Plan of Employee Representation

Our plan is known as the Harvester Industrial Council plan of employee representation, and was offered to the employees of the company on March 12 of this year. It was a frank invitation to them to participate in the determination of the policy of the company on all matters of mutual interest, including wages and hours, on an equal basis. They were invited to elect, by secret ballot, one-half of the membership of a works council whose function was to determine the policy of the company on the various items I have enumerated. The management appointed the other half of the membership. A guarantee of equal participation was had by the adoption of a unit ballot system. There are only two ballots cast. A majority of the employees' section determines their attitude and casts a unit ballot, as also does the majority of the management representatives.

These unit ballots have the same value, regardless of the number present on each side. The employees are guaranteed the right to a free performance and a free action in all of their activities as employee representatives. If there is any question of discrimination on their part, they may appeal directly to the president, and if not satisfied with his adjudication of the matter, it may then be arbitrated upon the selection of an arbitrator, mutually agreeable, whose decision would be binding upon both parties.

The plan was not put into effect at any plant which did not vote by considerable majority for it. It was first offered at the seventeen American and three Canadian plants. It was adopted at seventeen and failed of adoption at three. The day after the failure to adopt at these three plants petitions were circulated asking for another ballot and an opportunity of coming under the plan. The statement was made that the employees did not fully understand the plan on the previous day because it was written only in English. We have since published it in foreign languages because the employee representatives find it exceedingly difficult to convince foreign-born employees of the exact meaning of a certain clause if they themselves have to translate it.

We also made an error in the form of ballot. We use a ballot

stating "For adoption. Against adoption." We had some very good friends on the outside of the plant who were working against that plan and they told many employees, many foreigners, to vote on the bottom line, and when they saw the phrase "Against adoption" it did not mean anything to them and they voted according to instructions on the bottom line.

There was no positive effort on the part of the company to "sell" the plan. It was simply a dignified announcement. Each employee was furnished with a copy of the plan with a short résumé of a facsimile of the ballot, and asked to indicate, after three days of consideration, his wish for or against it. At the present time we are operating in nineteen of the twenty plants of the Harvester Company under this plan.

Another fundamental included in the plan is the guarantee of the protection of the employee against any discrimination because of race or sex or membership in any religious body or labor organization.

Function of the Works Council

The function of the works council is limited to the determination of the policy of the company with reference to wages, hours, recreation, health, sanitation, restaurants, and other matters of mutual interest. A policy having been determined, its execution lies wholly with the management. But the manner of execution being open to question at any time, it may be brought up through the works council. In other words, we have given to the employees equality in participation in the legislative and judicial functions, but not with reference to the executive. That, we believe, still lies wholly with the superintendent and foreman, and it is further accented in the procedure in bringing matters before the works council.

The plan states that any employee desiring to bring a matter before the works council shall present it first to the secretary, who shall ascertain whether it has been presented to the superintendent through the regular channels. If this has not been done, he shall see that it is done promptly. If the adjudication of the matter by the superintendent is not satisfactory to the employee or employee representatives, it then and then only comes before the works council. It must be presented in writing by the secretary to all members of the council at least three days before a regular meeting. The decision of the works council is final and binding.

When it agrees upon a matter—and it can only function through an agreement because the two ballots cast in opposition to each other completely deadlock the decision of the works council—it is forwarded to the superintendent for execution. In case the council deadlocks, it is then in order to reopen a discussion or propose an alternative or compromise resolution. If the deadlock still continues the matter is then referred to the president of the company, the highest executive officer, who is given ten days in which to propose a settlement acceptable to the majority of the employee representatives.

The General Council

If he fails to do that within the following five days he may elect to put it into arbitration direct, and arbitration is by mutual consent before a disinterested and non-partisan arbitrator, if one can be chosen. If not, each side selects one. If they agree, the matter is settled and their decision is binding and retroactive. If they cannot agree and choose a third arbitrator, a majority of the three is binding on both parties; or the president may elect to throw it before a general council—provisions being made that by such a reference, or in the event that a matter is introduced into a works council which is common to more than one other plant, the president may indicate the other plants which are interested, and call a general council of those plants, whereupon the works council originating the proposition ceases its consideration of the matter.

In a general council the employee representatives of each of the plants designated by the president send at least two of their representatives. For a general council they select one for each thousand employees or a major fraction thereof, but in no case less than two. The president names a number of management representatives, not greater than the total of employee representatives, and they function then exactly as the works council in regard to the method of ballot, etc.

Provision is made that either council may be recessed at any time and the employee representatives and management employees be privileged to withdraw and canvass their action. In a general council a recess may be taken to enable the plant representatives to consult with the other members of their works council. And provision is made, in order to do this, that the superintendent shall convene the works council in whole or any part of the employee representatives for conference with the representatives who have been elected to the general council. Their traveling, hotel and other expenses are paid while in the performance of this work.

After consultation with their plants upon a matter pending the general council may be reconvened, and decision is then binding upon all plants affected. Provision is made that all employees serving on the works councils shall be paid for the time they are so serving. They are privileged to call before them any employee of the plant to give testimony in a case under consideration, and the time of the employee so summoned is paid.

Provision is made, however, that in case it is not acceptable to the employee representatives to receive their money from the company, they are at liberty to arrange for a pro rata assessment of the employees directly. That was because of the objection which had been made by organized labor and other students of the subject to the general plan of paying employee representatives while serving as such.

Copies of the plan are available, and no less than 658 specific requests for them have come from other industrial establishments, from colleges and universities, from individuals, and from various sources.

Results Accomplished by Works Councils

We have been most agreeably surprised at the splendid results accomplished through these works councils since March 12, but surprised only at the rapidity with which they were accomplished, because there was no question in our minds as to what we would ultimately get.

There were elected by the employees 148 representatives in the 19 different plants. The average age of those employees is 38 years and 10 months. They are mature. A hundred and twenty-seven of them are married, and only 21 are single. Their average length of service is 7 years and 7 months, so they are relatively old-timers and mostly sedate married men. A hundred and two of them are native-born Americans, and 46 are foreign-born naturalized citizens.

Ninety-seven per cent of all of the employees who were present and eligible actually voted for or against the plan when it was proposed for adoption. The results at the various plants ranged from an almost unanimous vote for it to a vote of sixty to forty against it in two of the plants. One or two of the plants showed only a scant majority for the plan, considering the number of men involved, and we were somewhat puzzled at the time as to just what the result would be. For instance, at one plant the majority on the whole plan was only 200, and in one particular department—we will say the malleable foundry—the vote was 265 against the plan and 125 for it. And we thought that those 125 should be the only ones who would participate in the subsequent nominations and election, and we might then have a condition where only 65 of them would elect a representative for practically 400 men, which we could not feel was true representation. We were very much relieved, however, to learn that 98 per cent of all of the employees present and eligible actually voted at the nominations.

In the department just mentioned every man working on that day—nearly 400 of them—participated in the nominations, and again in the elections. On the final ballot for elections a nominating ballot was provided first in order that the elective representative might have at least a majority vote of his con-

stituents. It can easily be seen that if we had a department of 300 men and only one elective ballot and there were, say, 30 candidates running pretty evenly, possibly a man with only 25 or 30 votes would win the election. The nominating ballot makes it sure that at least a majority will be had by the successful candidate.

The average vote cast for the successful candidates at all plants was 68 per cent of the total, so that the winning candidates represented, or were elected, by more than two-thirds of their constituents. With a single exception, every local plant superintendent has written in response to an inquiry that if he had been permitted to select the employee representatives he would not have been able to choose a more satisfactory and more truly representative group than did the employees by their own secret ballot.

The Harvester Company has always operated under the open-shop principle, but a number of union men have been elected as employee representatives and are serving on works councils. Our experience shows that these men appreciate as readily as non-union employees the constructive possibilities of the plan and there is no indication that their participation in the co-operative activities of the council is not fully as satisfactory as that of the non-union representatives.

One of the first results under the plan was, naturally enough, a demand at several of the plants for shorter hours and increased wages. As one old-timer said, it looked very much as if the company was giving a sort of a Christmas party when it passed around those booklets saying that the works council would determine wages and hours.

With a single exception these requests were withdrawn voluntarily by the employee representatives upon presentation of the management's side of the case, which was to the effect that this was not an opportune time for such action—that the agricultural-implement business was a competitive industry. We were able to show that our wages and our rates were as high or higher than in similar industries in our own vicinity, and that only through constructive work in this council, through a greater efficiency in the reduction of the costs, would we be enabled to pay higher wages and still remain in a competitive market; and if they were willing to do their part we would do our part and exchange figures with them and show exactly what conditions were at any time, and when they felt that the time had come when we had better consider it again, we would do so.

In our experience thus far under the "Harvester Industrial Council" plan the works councils have been able to reach mutually satisfactory conclusions on all matters proposed with a single exception. That exception was in reference to a demand for a wages and hours revision, affecting about 25 per cent of the employees of one of the plants. The proposition as put up by the employee representatives did not meet the approval of the local management. After an extended discussion that was wholly friendly and frank, the ballot of the works council resulted in a tie. This was probably due to "an agreement to disagree," because both sides felt that the matter was one which could well be referred to the president for settlement and were entirely willing that this course should be followed.

Automatically the matter came before the president who was able to make a compromise offer to the employee representatives which met with their entire approval and at a special meeting, held four days after the original action had been taken in the works council, the proposal of the president had received the unanimous approval of the employee representatives and the matter was settled to the satisfaction of all concerned. In fact, it has resulted in a marked advance in the morale of the plant and the friendly attitude of the employees toward the council is doubtless more firmly established by the manner in which this matter was handled.

Probably 75 per cent of the actual business of the works council is translated outside of the regular meetings. Many suggestions or complaints have been brought to the attention of employee representatives and referred by them direct to the foreman or superintendent, who have promptly cared for the matter to the complete satisfaction of all concerned. This has been particularly true with reference to correction of ventilating equipment, improvement of shop practice, more convenient time of the weekly payday, occasional reviews of piece work rates and similar matters. This functioning of the council has been of especial value in acquainting the employees with the principles of time and motion studies, the reasons for adoption of certain shop rules, etc.

The employees have universally seemed appreciative of the opportunity to familiarize themselves with the facts as to any situation and have been exceptionally fair in passing judgment after complete discussion. They have displayed particular interest in production problems and seem to realize that the basis of larger returns to them for their labor lies in an increased production and more efficient operation of the shops.

Some of our plants are in the middle west side of Chicago, right in the heart of the radical district. Another in particular is out on the far south side, where probably you have read of race riots in Gary and Indiana Harbor and that vicinity.

I believe firmly that there is a well-organized propaganda on foot to start Soviet organizations in this country, and to play up the rebellious spirit in the foreign element in the vicinity of some of our shops.

The foreign members of one of our works councils desiring to meet this movement, asked for information which enabled them to get up a report showing the participation of the foreign-born employees in military service of this country. They drew parallel columns of the number of foreign-born employees per thousand of the men at the plant; and the number of each nationality per thousand who engaged in the military program. The average for the whole plant, of all the employees engaged who went into military service was 22 per cent. It was much higher at the other plants. The average of all the foreigners was 22.2 per cent, practically the same, but particularly the average of the Polish people against whom sentiment had been directed, and against whom a definite campaign was being waged in playing up their racial spirit, was 36 per cent.

The average participation of the Poles was greater than that of the Americans. And then they drew some conclusions: that the foreigner, while he was not a citizen, and therefore not bound by the same ties as the American, had contributed almost the same to the military program, and individual nationalities to a greater extent than had the Americans; that his contribution had really been much greater from the fact that he was not a citizen, not bound by those ties; and they drew the conclusion that the anti-foreign sentiment which was being engendered was all wrong and not justified by facts.

Now, that was done in the works council committee on publicity without any instigation by the management whatsoever. It was the thought of the men themselves as to how they might compete with this insidious and destructive propaganda.

Responsibilities Undertaken by Works Councils

We had a restaurant which was not very satisfactory. It was losing money for us and not getting the results which we wanted. We turned it over to the works council and the patronage has trebled since that time. It no longer shows a deficit. It was frankly and freely turned over to the men to manage. They hire their own manager, they make their own rules, they set their own prices, and they have learned something about the restaurant business that we wanted them to know, and something of its trials and tribulations, and we have "sold" the proposition entirely.

We have had one or two requests for reinstatement of discharged employees. We have functionalized employment bureaus and all recommendations for men on the part of foremen are reviewed at the employment office. There are no restrictions in our plan as to what may come before the works council. In two cases—the only cases thus far that have been presented—the works council by unanimous vote upheld the decision of the employment manager and refused to reinstate the employee who thought he had a just grievance.

The safety program has been rejuvenated. We thought we

were getting up efficient bulletins and we thought we were carrying our message all the way down the line. We thought that our safety program was satisfactory, and we couldn't go much farther with it. Since the inauguration of the works council, however, our accident-frequency rate has steadily fallen month by month. The character of the bulletins has changed somewhat. They are written in shop parlance, and by the men on the safety committees.

The sub-committee organization activities of the works council have been wonderfully well arranged by the employees themselves without any action of the management. They have unanimously said that they do not want a grievance committee. They do not want any committee on wages and hours. Those are subjects that they want to come out for a full discussion in the works council, and their reasoning was somewhat along these lines: They said, "If we had a grievance committee which only went to the boss on controversial matters, he couldn't help but get down on us a little bit, and believe that we never think of anything except how to make trouble. And we don't want to have that put up to just one or two men, we want the whole council to work on that; and then, too, we have this feeling that if a man comes to us with a grievance or a request for piece-work revision, or revision of prices or hours, we don't ourselves want to say to him, 'Well, you go over in the blacksmith department and see John Doe, because he is on that committee. We don't want to have anything to do with that.' Those are things they want us to get into, and if we do, we want to do it to our complete satisfaction."

The sub-committee activities, so far as grievances and hours and wages have been concerned, are always taken up by the council as a whole, and it has meant that no one or two individuals sat themselves up as business agents in the plant.

The question has been asked how much of this human relations problems lies within the field of the mechanical engineer. Engineering, to my mind, has been the consideration of an exact science, and these matters of personnel in the industrial sense are not reducible to stable factors at all. In the whole scale of industrial relations we are always dealing with the human being—a body with a mind, a creative force, and a soul, and therefore not reducible to any sort of stability as regards its valuation. You can't get up any sort of a formula which will solve a given condition, and repeat on it. And I don't believe the personnel problem ever should be treated as a science and coldly analyzed or formulated.

I believe that its direction and its constant progress should be made by men, not necessarily technical in their education, although we do need the assistance of every bit of science that can be brought to bear, but more particularly men who are given over to the idea of real service.

There are many employment managers functioning today in splendidly furnished, mahogany-lined offices, and who receive the requisitions from foremen for help and who analyze the jobs' specifications quite technically, and select by means of phrenology, and goodness knows how many other "ologies," applicants from the waiting line, if there is such a thing, or by scientific advertising, if the waiting line is not there, and possibly fill those jobs.

But I believe the work is best done by men who forsake the office and don't hire through an employment window but get out and interview a man across a desk, and look upon him as another human being, one who is coming into a strange land, into a strange company, and make him thoroughly at ease; who will sell him his job as a constituent part of a great assembly, who will look after him, not in an apparently disinterested way, but in an atmosphere of good-fellowship after he goes to work, and who will look upon his problems with a light of experience and know exactly, or nearly exactly, what his thoughts are, what his suspicions are—and those I do not think can be had by a science as well as by experience.

I think the employment engineer of today—the personnel manager of today—should first of all be chosen on personality. That is certainly more than fifty per cent of the necessary make-up. He should be of an engaging personality, a man who can converse with other men and get them in turn to converse with him; who has a sympathetic ear; who has a certain poise; and withal, who is a good, keen judge of human nature. And then on top of that, as much technical training as he may have.

The direction of the movement lies with all of us, for back of it all is this industrial unrest, a manifestation of political and social unrest, and it concerns every one of us as citizens that American industry shall do business on the square, that the structure of American industry shall be fundamentally sound, and that the correction of any improper practice and wages and accidents and conditions may be had through the instrumentality of collective bargaining and simply changing the conditions themselves that are causing the unrest, rather than by completely overthrowing the structure.

It is then, I believe, that we will have exercised an important reaction upon the community as a whole, and that that reaction will be manifest in keeping from our shores this menace of Bolshevism which now looms black on our horizon.

MOTOR GASOLINE

Information regarding the desirable properties of gasoline and the best methods of testing it are contained in the Bureau of Mines Technical Paper 214, written by E. W. Dean.

The desirable properties of gasoline are summarized as follows:

1 The gasoline should not contain too large a percentage of highly volatile products, which tend to cause large evaporation losses and excessive danger in handling and storage, but should have enough volatile constituents to permit starting an engine under reasonably unfavorable conditions, without preheating.

2 The gasoline should not contain any considerable percentages of heavy or non-volatile constituents, which after atomization into the engine cylinders cannot be completely vaporized and burned.

3 The gasoline should not contain material that after combustion leaves a residue that collects in the motor.

4 The gasoline should be free from substances that attack metal, either before or after combustion. Unremoved acid (used in refining) falls under this head.

5 Neither the gasoline nor its products of combustion should have a strong or markedly disagreeable odor, as this is objectionable to users of automobiles.

6 The gasoline should be free from non-combustible material such as water and sediment.

As already stated, the Bureau does not believe that one set of specifications is satisfactory for all needs. The following system is suggested, however, as a simple and satisfactory scheme for regulating the quality of ordinary automobile gasoline:

Color. Water-white—to be determined by inspection of the vertical column in a 4-oz. sample bottle or 100-cc. graduate.

Acidity. Total absence of free or combined acid—to be determined by testing with any satisfactory indicator, the water extract obtained by shaking thoroughly with 1 cc. of distilled water the residue in the flask after completion of an analytical distillation.

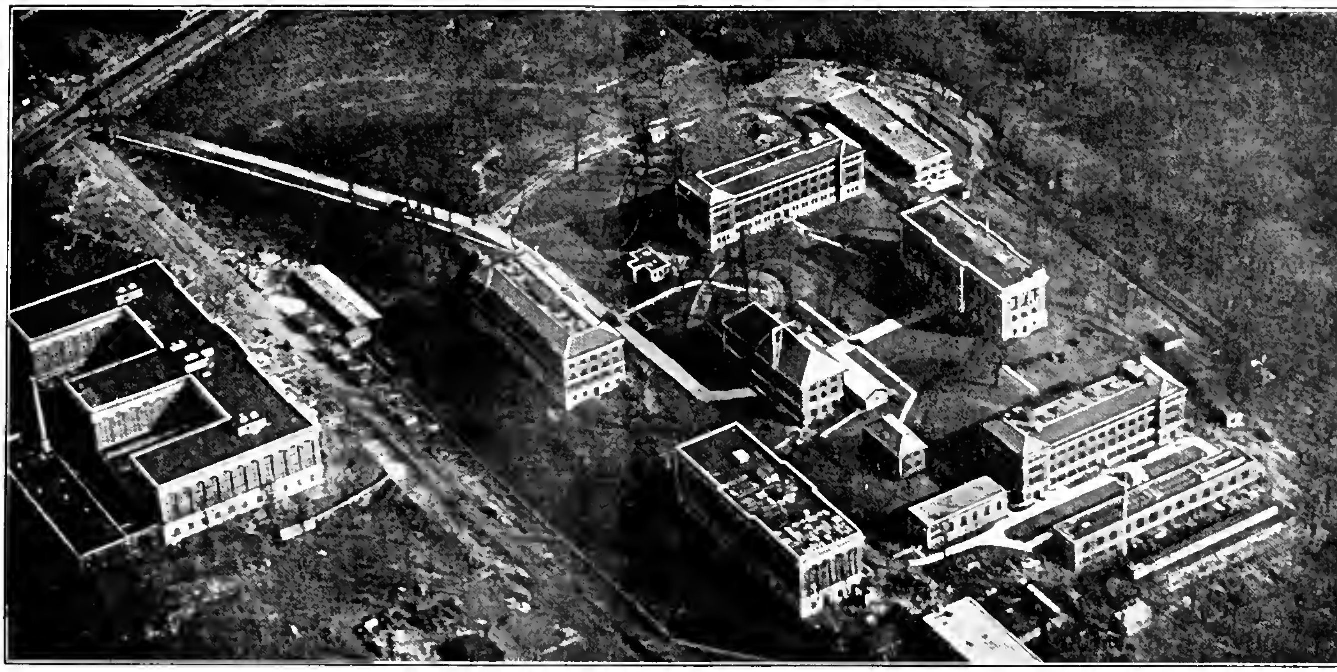
Volatility. The Bureau recommends a method of distillation similar to that adopted by Sub-Committee XI of Committee D1 of the American Society for Testing Materials (see A. S. T. M. Yearbook for 1915, pp. 568-569), the only two noticeable points of variation being the manner of reading temperatures against fixed percentage points and the use of a thermometer of lower range. The requirements for volatility are that when gasoline has been distilled by the bureau's method it should meet the following requirements:

a The temperature read on the thermometer when 20 per cent has distilled should not be below 70 deg. cent. (158 deg. fahr.), nor above whatever limit is fixed after due consideration of conditions of use.

b The temperature read when 90 per cent has distilled shall not be above another limit similarly chosen.

c The temperature read when 50 per cent has distilled shall not be higher than a mark halfway between the upper 20 per cent limit and the 90 per cent limit.

d The dry point shall not exceed the 90 per cent limit by more than 40 deg. cent. (72 deg. fahr.).



BUREAU OF STANDARDS, WASHINGTON, D. C., TAKEN FROM AN AIRPLANE

Condition of Research in the United States

BY ARTHUR M. GREENE,[1] JR., TROY, N. Y.

This paper, by the Chairman of the Research Committee of the A.S.M.E., deals with the conditions under which research is now being carried on in the United States. The author first discusses research in its relation to the technical school and engineering experiment stations. Cooperative research and the research activities of the Government are next presented and finally the author considers commercial and industrial research work. The complete paper contains lists of the educational institutions having mechanical engineering laboratories, of the private research laboratories and of manufacturing companies having their own research facilities.

HISTORY records the development of science from fortuitous observations and from systematic, careful and exhaustive research. The work of the Greeks as shown by Lucretius on the constitution of matter could only have been made after a careful and exhaustive study of the laws of nature. The work of Hippocrates certainly indicates a previous study of anatomy and the action of certain drugs. The studies of Galileo and Newton, of Kepler and Herschel, of Watt and Stephenson, tell of careful thought applied to the interpretation of facts which led to the establishment of laws. The story of Berzelius and his kitchen laboratory illustrates the spirit of adventure into the unknown which brought to us our early quantitative knowledge of the elements. The accidental observations of Galvani, Newton, Bell and Crookes by future development and study led to results of incalculable value to science, while the theoretical studies of Kepler, Maxwell and Hertz predicted results which in giving confirmation to theory gave also confirmation to the correctness of experimental observations.

Although all past ages have had men devoted to research, they are not numerous in any one period. If there is one thing, however, that marks the present epoch, it is the prevalence of this idea. In the past, research was carried on by the few, but today as a result of education and as a result of the success of research in many fields one can scarcely read a periodical of any branch of science without finding some article on this subject. For the last fifty years the commercial value of research has become more and more evident to industrial plants. This appreciation has been coincident with the growth of these plants and has made their development possible, while reciprocally the growth of the plants has made extensive research possible.

For many years our colleges and universities have had their laboratories where some research has been done, and with the development of our industries following the Civil War the necessity of commercial laboratories for examining or controlling products was evident. The search for knowledge by some of the investigators and the possibility of application of the results of their researches undoubtedly reacted, so that the laboratories of examination and control became laboratories for investigations in new and unknown fields.

Research work, quite general before the present war, became more extensive in overcoming the dastardly appliances of the Hun in devising new apparatus, products and manufacturing methods and in improving quality and production. The war has demonstrated, if demonstration was necessary, the value of research, and it is now the opinion of most of us that this stimulating viewpoint should not be lost and that the war-time interest should be continued.

Before discussing the matter of the physical condition of the various laboratories there are a few general considerations which should be mentioned. The cost of research in the past has been such that in many cases it could only be undertaken in an extensive way by large corporations. The necessity and value have been evident but the small plant has been unable to inaugurate that which it has known to be of value. In other instances there have been investigations which have been of such a nature that there would be no commercial gain from their results, although of great use to mankind. The necessity of such work has been clearly seen and appreciated by some, and in this country institutions and foundations have been established by public-spirited citizens to carry on investigations or to give grants to those who are

[1] Professor of Mechanical Engineering, Rensselaer Polytechnic Institute. Mem. Am. Soc. M. E.

Presented at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

working on problems for the general good. The reference is to such organizations as the Rockefeller Institute for Medical Research, the Carnegie Institution of Washington, and the Sage Foundation.

A number of private commercial laboratories have been undertaking commissions for clients, but recently the plan worked out years ago by the Associated Factory Mutual Fire Insurance Companies of New England in their coöperative laboratory and the Insurance Engineering Experiment Station has been applied in the coöperative work of certain industries. These investigations have been undertaken by an industry as a whole or by group of manufacturers, and the results have been distributed among the contributors to the expense funds, or, in certain cases, the results of the experiments have been freely given to the world.

Research in Technical-School Laboratories

To turn now to the present research activities, let us consider first our universities and technical schools. The general equipment of the university laboratories is planned to give training to the undergraduate in methods and to illustrate certain laws. The engineering laboratories are equipped so that research work is possible, but in many cases the schedule for instruction work is so heavy that little or no research work can be done. Nevertheless, under these adverse conditions some work of great value has been produced during the last thirty years in the technical schools by faculty members, graduate students and even by undergraduates. The lack of time for experimentation has been cared for in the engineering experiment stations by the employment of full- or part-time investigators. In this way work can be carried on continuously to a conclusion. At present the disorganization of these laboratories by war activities has caused most of the work to cease. A return to normal conditions, however, is looked for within a year. The laboratories of chemistry, physics, biology and the other sciences have been doing much graduate research work. This has been of a theoretical nature rather than of the applied form of research more evident in our engineering laboratories. The small number of graduate students of engineering has partially accounted for the limited amount of research from the engineering schools.

The equipment of these technical schools is usually quite diversified and adapted for research work of a varied nature. The equipment has been planned in many cases for certain problems and in some instances contributions have been made by some associated industries for equipment to make investigations of problems of that industry. Thus, at Johns Hopkins University the gas interests in and around Baltimore donated a fund for the equipment of a laboratory to study gas manufacture and its by-products. At the Carnegie Institute of Technology at Pittsburgh a laboratory for rolling-mill research and instruction is being established from funds which are contributed by a number of steel manufacturers.[1]

One of the great needs of the present time as voiced by directors of a large Government laboratory and of a large commercial laboratory is the need for more research men. Research demands a man of clear vision, great imagination, tremendous resources, absolute honesty, good training and devotion to work. The love of the work will have to be the incentive as in many cases the monetary returns are small. If our colleges of engineering and science could by some means instill into more men the great desire for discovery through research, they would aid much in the contributions of this age to the future. Training is also necessary, and that should be done by men engaged in research.

Engineering Experiment Stations

To aid the work of research for the industries and manufacturers by supporting men on whole or part time to carry out investigations, engineering experiment stations have been established in many state universities. These have been active and the development of such institutions is considered by some to be of such national importance that several bills have been introduced in Congress for Government aid in establishing them throughout the United States.

The Engineering Experiment Station of the University of Illinois, organized in 1903, usually comes to mind when discussing this question, although there are fourteen such stations at other state universities. The Engineering Experiment Station of the University of Illinois up to January, 1919, has issued 110 bulletins and 10 circulars on its researches. Twenty-eight of these deal with structural problems, 28 with problems relating to fuel, its mining, storing, combustion and analysis, 10 with problems of mechanics, strength of materials and machine design, 14 with heat problems and 11 with problems of electricity and electrochemistry. These papers are sent free of cost to interested parties in some cases, and in other cases a nominal charge is made.[2]

Coöperative Research

While discussing the subject of the experiment station, the possibility of the coöperative research as shown by present conditions and the different methods of solving this problem should be mentioned. The problems of hot-air furnace heating have been solved by empirical rules which have had little if any scientific foundation. An association of builders of hot-air furnaces has granted the Engineering Experiment Station of the University of Illinois certain funds of money to finance an investigation of these problems, the results of the investigation to be made public at its conclusion.

The problems of metal rolling are complex and have been studied in the past with difficulty because investigations must not interfere with production. The coöperative plan of equipping a full-size rolling mill at the Carnegie Institute of Technology equipped with special apparatus for varying conditions and making quantitative determination of different data exemplifies what is being done by another industry.

The Mellon Institute of Research of the University of Pittsburgh is unique and illustrates a development of research by funds contributed to a laboratory by individuals, corporations or industries for the solution of problems confronting them. The Institute was organized about thirteen years ago by Dr. Robert Kennedy Duncan, and the contribution of funds for the support of the research was continued by each contributor for one or more years. The money so received served to pay the salary of the man or men on a special piece of research work and to pay for very special apparatus. The Institute houses the research, furnishes ordinary supplies and apparatus, affords library and consultation facilities and directs the work. The investigations are made for the donor and the results belong to him. At present the work is under the charge of a director, acting through two assistant directors in charge of the fellows on individual and multiple fellowships. In the Institute a method of developing complete unit experimental plants to study processes for certain donors has been used. In this way commercial processes have been developed from laboratory research in a way not done in many other research laboratories.

A list of coöperative efforts in research must mention the work of the laboratories of the Factory Mutual Fire Insurance Companies. The work of this association has covered many years, some of its bulletins being issued over thirty years ago. Many papers and discussions were contributed to the early Transactions of this Society from its staff.

Government Activities in Research

The Bureau of Standards at Washington and Pittsburgh, the laboratory of the United States Geological Survey at Pittsburgh, the Food Laboratory and Forest Products Laboratory of the Department of Agriculture and the Naval Experiment Station at Annapolis, are a few of the Government activities interested in research.

[1] A list of 78 educational institutions having mechanical engineering laboratories is given in the complete paper.

[2] A list of 14 universities having engineering experiment stations is given in the complete paper.

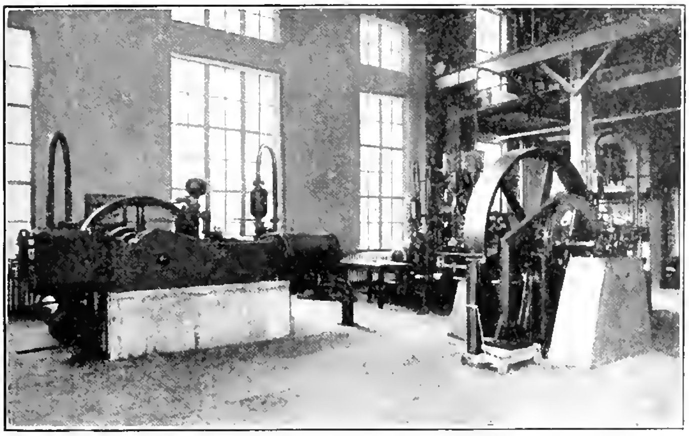
At the Bureau of Standards research work is being done in physics, chemistry, metallurgy, manufacturing and engineering. There is hardly a branch of human endeavor which is not touched by this enormous research laboratory. In 1917-1918 there were over 1400 employees connected with the Bureau, and accounts aggregating more than $3,400,000 were handled. During this year the Bureau issued fifty-three publications, and these may be obtained through correspondence.

The primary work of the Bureau is the definition and fixing of standards of measurements, standard constants, standards of quality, standards of performance and standards of practice, and to do this they have divided the scientific and technical staff into a division of weights and measures, a division of heat and thermometry, an electrical division, an optical division, a chemical division, a materials division, an engineering research division, a metallurgical division, and a ceramic division. Each division is under a Chief of Division, and under him there are numerous experts and assistants. The Bureau feels that its function is one of service to the nation, and it endeavors to aid all who apply for information or guidance.

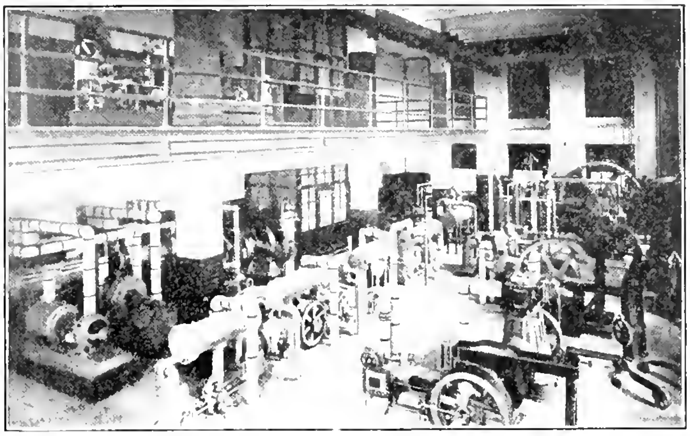
The work of the Gage Section of the Bureau of Standards during the recent war activities must be remembered as of the greatest importance. This department undertook to regulate the gages used in the various manufacturing plants through its headquarters in Washington and its branches in the East and the Middle West. The Section has developed instruments for testing screw-thread gages for profile and pitch, instruments for end measurements, and, in fact, it is prepared to test any commercial gage or templet for accuracy. The Section has studied the salvaging of gages and is vitally interested in the problems of duplicate production.

The activities of the laboratories of the Geological Survey and the Department of Agriculture are devoted to their special fields of endeavor, and in each case scientists of training and experience are in charge of the research.

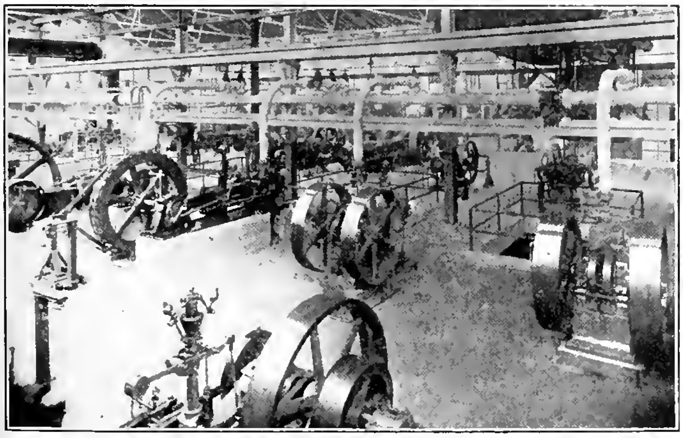
The U. S. Naval Experiment Station at Annapolis, Md., is used to study the apparatus and materials used by the U. S. Navy or certain Government bureaus. The work consists in making tests on these, and in addition researches regarding the general laws underlying the apparatus have been undertaken. The Station is well equipped with apparatus and an excellent staff. The work of the Station is for Government information, but frequent papers by members of the staff appear at times before various technical societies.



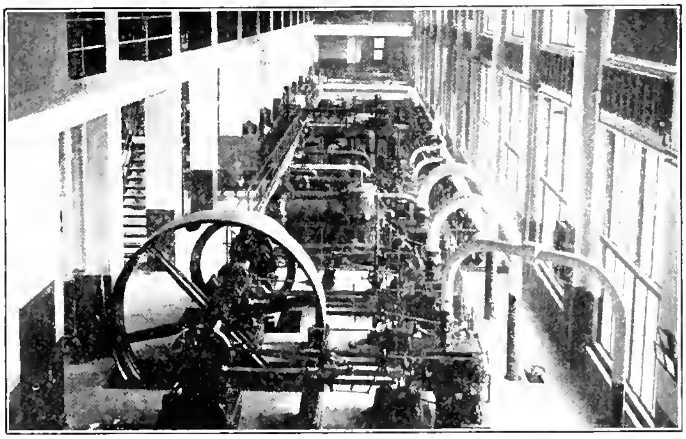
JOHNS HOPKINS UNIVERSITY



RENSSELAER POLYTECHNIC INSTITUTE



UNIVERSITY OF ILLINOIS



MASSACHUSETTS INSTITUTE OF TECHNOLOGY

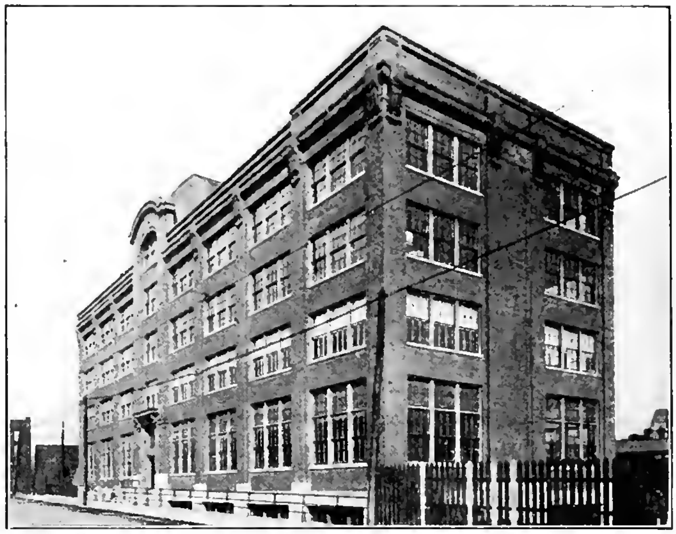
MECHANICAL ENGINEERING LABORATORIES OF TECHNICAL SCHOOLS

The Forest Products Laboratory of the United States Department of Agriculture at Madison, Wis., is devoted to problems relating to the applications of forest products.

The Watertown Arsenal is equipped for research in materials of engineering. The reports from this laboratory have been for years the source of many data on the strength of materials. The Philadelphia Navy Yard is equipped for research in fuel oils, while the Washington Navy Yard is equipped for testing ship models, propellers, airplanes and air propellers. The wind tunnels and testing basin are of special merit.

The research activities of the American Society of Heating and Ventilating Engineers in connection with the Pittsburgh Laboratory of the United States Geological Survey is important and illustrates the activities of certain groups of scientists and engineers. This society plans to make researches regarding problems arising in its field of endeavor for the benefit of the profession and the public. In this project the expenditure of $20,000 per year for a number of years is proposed.

Laboratory of the General Electric Company



Laboratory of the Pennsylvania Railroad

Commercial Research

The private research laboratories of the country are primarily devoted to investigations of materials for commercial purposes, to check products or raw materials or to improve the product. These are quite numerous, and the list of laboratories given in the complete paper shows in a partial way the private research resources of our country. Much of the work done by these laboratories is of the nature of inspection, but in many of them the commissions undertaken for clients have been of a true research nature, in finding the cause of defects, the methods of improving product and in some cases planning actual production methods or processes. Many of these laboratories have been in existence for almost a half a century; others have been developed in the last decade from a local need for such institutions.

The work of these private laboratories covers all fields of investigations and new equipment is obtained in many cases for special investigations. In some cases a laboratory has been specializing in problems of a definite character and its equipment for this work is expensive and complete.

Industrial Research

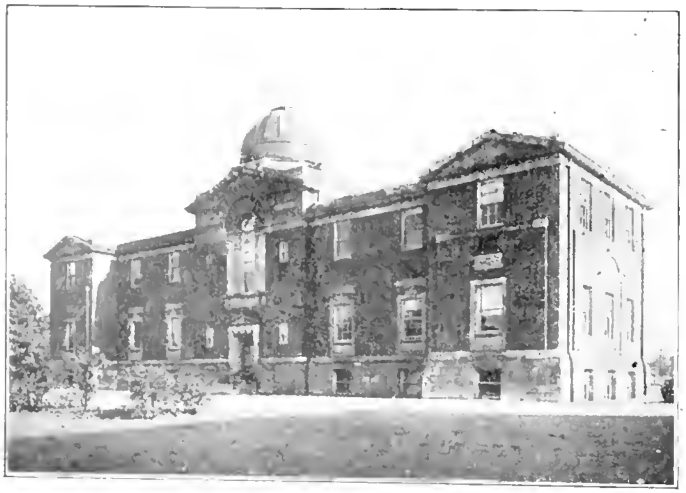
The last division of research activities is the one which undoubtedly represents the largest expenditure of money for operation, maintenance and equipment. It is the one including the various laboratories of the manufacturing plants of the country.

These laboratories occupy two fields, one the examination, inspection and testing of raw materials or finished products, in which the laboratory is called in many cases the test laboratory; the other concerned in determining physical and chemical properties and constants of materials, the investigation, development or invention of new methods, processes of manufacture, or even of products and the testing of these new schemes, in which case the laboratory is termed the research laboratory. In many instances the test laboratories are devoted to routine work, while in others researches of importance are carried out in the test department. In some organizations the laboratory combines both features under one head.

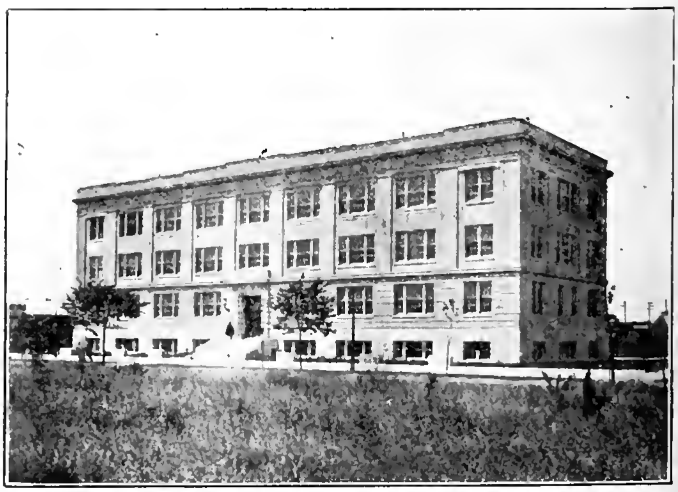
One of the oldest and largest of the laboratories of the corporations is that of the Pennsylvania Railroad at Altoona, Pa. It was established in 1874, and at present its staff of workers is over six hundred men, half of whom are engaged in inspection work. The expenses of this laboratory are about $500,000 per year, and the work of the department is the preparation of specifications for materials and supplies of the Pennsylvania System.

The locomotive testing plant, which was such a prominent part of the St. Louis Exposition, has been used at Altoona for further work in locomotive research. For studying problems on the road a dynamometer car is used by the laboratory. A unique part of their equipment is a laboratory car which may be sent to various parts of the system for the solution of local chemical problems or for other purposes.

The laboratories of the Westinghouse Electric and Manufacturing Company at Pittsburgh, Pa., and of the General Electric Company at Pittsfield, Harrison, Cleveland, Lynn and Schenectady, represent the large laboratories of the manufacturers of electric apparatus. In both of these companies the main research

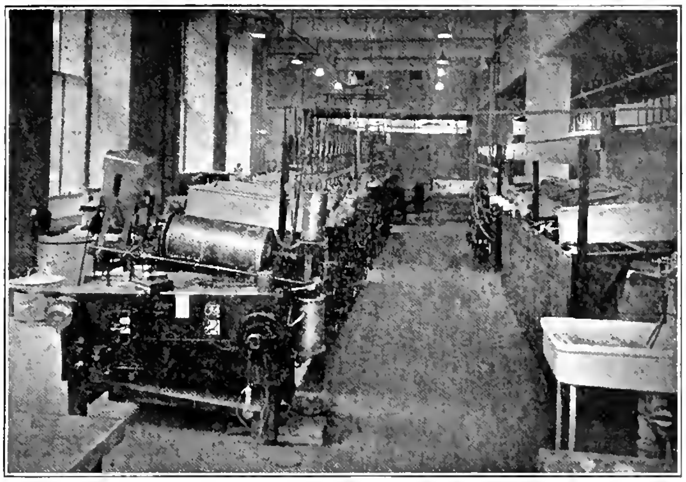


Laboratory of the National Lamp Works



Laboratory of Arthur D. Little, Inc.

Physical Laboratory of the Pennsylvania Railroad



Section of the General Electric Laboratory

laboratories have forces of more than one hundred men, and the budget of each amounts to $500,000 per year.

In the Schenectady plant of the General Electric Company the department of tests is independent of the research laboratory. The research laboratory is devoted to problems of the development of new materials, processes and apparatus, and, as its name indicates, its work is of a research nature.

Work in pure science, which at the inception has no commercial aim in view, is one of the activities of this laboratory and the publications of its results in the transactions of scientific societies gives evidence of such work. The results of these investigations in some cases have led to results of great commercial value—as in the case of the gas-filled lamp, which had its origin in a research on the laws governing the loss of heat from small wires coupled with an investigation on the evaporation of tungsten.

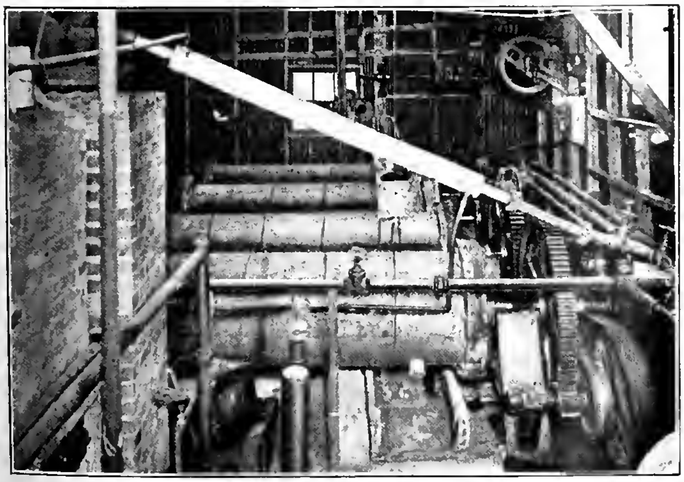
The research laboratory has as another of its functions the development of processes or of improved or new materials. The method of producing drawn tungsten wire, the production of insulating material, the improvement of transformer steel and the investigation of alloys represent certain of the problems of this laboratory. Here science has been applied for a definite commercial end. Another function of the laboratory is to make certain products for which there is but a limited demand. Thus the Coolidge X-ray tube, certain tungsten products and targets for X-ray tubes are manufactured in this laboratory.

The equipment of the laboratory is most complete for its activities. There are sixteen machines in its power plant giving power at different voltages and frequencies. Frequencies from 25 cycles to 2000 cycles may be had and by transformers voltages as high as 200,000 or currents of 12,000 amperes may be obtained. The building is piped with city water, river water, illuminating gas, high-pressure hydrogen, low-pressure hydrogen, oxygen, high-pressure steam, compressed air and vacuum suction and vacuum cleaning. Distilled water is supplied to any room by gravity, and liquid air may also be obtained. Various kinds of gas and electric vacuum and arc furnaces are installed in one part of the building. A furnace is installed for argon purification. Various crushers, grinders, rolls, punches and a 60-ton hydraulic press are installed.

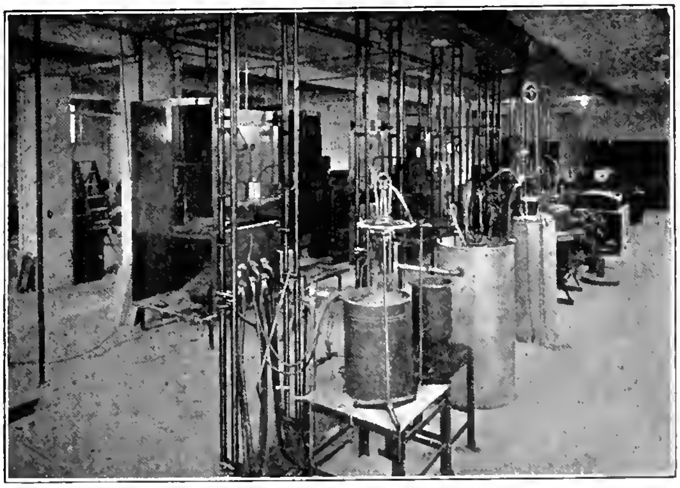
The illuminating laboratory, which is distinct from the research laboratory, is devoted to special problems in studying the best lighting units or methods of utilizing these units. The consulting engineering department laboratory, devoted to high-tension phenomena, the testing laboratory for materials, the standardization laboratory for instruments and the development of new instruments represent activities at Schenectady which are devoted to research in their commercial routine duties. Many engineering departments are constantly making investigations which are of a research nature.

The work at the laboratories at Lynn and Pittsfield is largely applied to the production problems of these plants, and at Harrison and Cleveland the problems of lamp production are studied. The problems of the Westinghouse Company are of a similar nature to those of the General Electric Company.

The research laboratory of the Eastman Kodak Company represents the research activity of another manufacturing corporation. The staff of this laboratory consists of about fifty men, some fifteen of whom are specialists. The budget amounts to more than $100,000. The work of the laboratory is devoted to physics, chemistry, to plant problems and new development. In



The Mellon Institute's Experimental Plant for the Treatment of Phosphate Rock



Metallurgical Laboratory of the Westinghouse Electric and Manufacturing Company

this laboratory full-size apparatus is used at times in making research. As shown by the equipment of many laboratories, the study of complete processes in the laboratory on a commercial scale is one of the features of the times. The problems of this laboratory are organic, inorganic and colloidal chemistry, optics, color photography, film products and applications of general photography, chemical products and emulsions.

The laboratory of the National Lamp Association, now the Nela Park Laboratory at the National Lamp Works of the General Electric Company at Cleveland, Ohio, represents one of the best-known research institutions of this country. The research work of this laboratory is devoted to the physics, physiology and psychology of light, the production, utilization and efficiency of luminous energy. In this laboratory, with a staff of eight investigators of the highest ability directing the work, all kinds of illuminating problems are studied from every angle. The laboratory has a policy of sending out its experts to study local conditions, and in many cases investigators from other institutions come to this laboratory to carry on research. During the first eight years of its existence from 1908 the laboratory has produced 125 high-grade papers. These are abstracted by the authors and the abstracts published at intervals. In having abstracts made by the authors the important points of the researches are sure to be covered.

The great extent of research facilities is disclosed by the list of laboratories used by the Research Committee. This list, comprising ninety-four manufacturing companies having research laboratories, will be found in the complete paper.

Still another agency which not only has been of utmost importance during the present war, but also in its continuance in the times of peace, will have a still greater influence on the developments in science and industry is the National Research Council, the purpose and work of which is best explained by the following executive order issued by the President of the United States, May 11, 1918:

The National Research Council was organized in 1916 at the request of the President by the National Academy of Sciences, under its Congressional charter, as a measure of national preparedness. The work accomplished by the Council in organizing research and in securing coöperation of military and civilian agencies in the solution of military problems demonstrates its capacity for larger service. The National Academy of Sciences is therefore requested to perpetuate the National Research Council, the duties of which shall be as follows:

1. In general, to stimulate research in the mathematical, physical and biological sciences, and in the application of these sciences to engineering, agriculture, medicine and other useful arts, with the object of increasing knowledge, of strengthening the national defense, and of contributing in other ways to the public welfare.

2. To survey the larger possibilities of science, to formulate comprehensive projects of research, and to develop effective means of utilizing the scientific and technical resources of the country for dealing with these projects.

3. To promote coöperation in research, at home and abroad, in order to secure concentration of effort, minimize duplication, and stimulate progress; but in all coöperative undertakings to give encouragement to individual initiative as fundamentally important to the advancement of science.

4. To serve as a means of bringing American and foreign investigators into active coöperation with the scientific and technical services of the War and Navy Departments and with those of the civil branches of the Government.

5. To direct the attention of scientific and technical investigators to the present importance of military and industrial problems in connection with the war, and to aid in the solution of these problems by organizing specific researches.

6. To gather and collate scientific and technical information at home and abroad, in coöperation with Governmental and other agencies and to render such information available to duly accredited persons.

Effective prosecution of the Council's work requires the cordial collaboration of the scientific and technical branches of the Government, both military and civil. To this end representatives of the Government, upon the nomination of the President of the National Academy of Sciences, will be designated by the President as members of the Council as heretofore, and the heads of the departments immediately concerned will continue to coöperate in every way that may be required.

The White House, May 11, 1918. (Signed) WOODROW WILSON.

The National Research Council was under the chairmanship of Dr. George E. Hale, with three vice-chairmen, an executive secretary, a treasurer and two assistant secretaries. The executive board, under the chairmanship of Dr. John J. Carty, consisted of the officers of the Council, the chairman and vice-chairman of divisions and the chairman of sections of the General Relations Divisions, together with six elected members. The Divisions of the Council were as follows:

1 The Division of General Relations
2 Military Division with its Research Information Service
3 Division of Engineering
4 Division of Physics, Mathematics, Astronomy and Geophysics
5 Division of Chemistry and Chemical Technology
6 Division of Geology and Geography
7 Division of Medicine and Related Sciences
8 Division of Agriculture, Botany, Forestry, Zoölogy and Fisheries.

Each division was divided into committees and sections, covering special features of the work. There were over one hundred scientists representing various technical and scientific societies, educational institutions, commercial laboratories and manufacturers.

The work accomplished by the Council during the war has been so important and many of the investigations and researches which were not completed gave so much promise for the future that the Council has been reorganized to continue its work for the furtherance of science and its applications.

Warping of Aircraft Propellers

During the war one of the greatest troubles experienced with airplane propellers was caused by the warping and twisting of the blades near the tips, and a large percentage of the propellers received at the front were rejected on this account. In order to determine the causes and to develop methods of preventing this trouble, a number of experimental propellers were manufactured for the War and Navy Departments by the Forest Products Laboratory of the U. S. Forest Service at Madison, Wisconsin. The propellers were made of Central American and African mahogany using carefully selected stock uniform in density and moisture content, and were stored under uniform atmospheric conditions for 30 days between the roughing out and final carving operations. After the standard finish, consisting of five coats of spar varnish, had been applied, they were again stored under the same conditions for observation as to warping and twisting.

These propellers were made up and handled much more carefully than the commercial product, and every possible effort made to produce perfect results. After exposure to a very damp or humid atmosphere for three or four months, it was found that every propeller had warped or twisted or otherwise changed shape to an extent that made them unacceptable for use. They had all absorbed about five per cent of moisture through the five coats of spar varnish, and this moisture caused all the trouble. The treatments to which these propellers were exposed, namely, being manufactured in a relatively dry condition and later exposed to moist atmosphere, is very similar to that which is normally received by propellers made in the United States and shipped to France. Frequently propellers are made in a relatively moist climate and shipped to a drier one, and trouble from change of shape due to drying out is almost sure to result.

These changes may be prevented either by applying a moisture-proof coating or by keeping the propellers under uniform atmospheric conditions throughout their life. At present, the aluminum leaf coating developed by the Forest Products Laboratory is the only practicable moisture-proof coating which has been successfully applied to propellers. It is not possible to keep propellers under absolutely uniform atmospheric conditions during manufacture and service, but these conditions can be approached by making up the propellers at the moisture content which they will normally reach in service. Propellers made up this way and coated with aluminum leaf have the best possible chance of giving high efficiency and long service.—*Technical Notes, Forest Products Laboratory, U. S. Forest Service.*

Research Work on Malleable Iron

By ENRIQUE TOUCEDA,[1] ALBANY, N. Y.

This paper contains an account of four years of research work undertaken for the American Malleable Castings Association as a plea for industrial research among manufacturers and as a striking example of what such research can accomplish. The author outlines the organization and purpose of the Association and shows how the quality of the product of its members has steadily increased since the beginning of the research work. Malleable-iron castings, due to lack of uniformity and dependability, were rapidly being replaced by other materials. There were many fallacious ideas and theories regarding the physical properties of such castings and the methods of annealing them. Records of tests of 1-in. bars from seven different concerns made by the author in 1911 showed that the average ultimate strength was 39,882 lb. and the elongation under 5 per cent. A report dated March, 1919, to the members of the Association, each of whom regularly submits test bars from some one heat of each day's run, showed that 44 per cent of the test bars submitted during that month had an ultimate strength over 52,000 lb. and an elongation of 14.67 per cent, indicating the progress made since research work was undertaken.

The records of tests also show that, contrary to generally accepted theory, the elongation increases with the ultimate strength. The purpose of the Association, however, is not to increase ultimate strength and elongation, but to increase the uniformity of a product upon which the engineer can rely, and this is being accomplished through exhaustive research and advice to members through the consulting engineer of the Association.

A description is also given of the process of manufacturing malleable iron, of the air furnace, and of the annealing ovens and the annealing process. In the complete paper there will be found a discussion of the structures of iron containing both free and combined carbon, and the metallurgy of cast iron, numerous micrographs of typical structures being given in connection therewith.

The effects of the time element in cooling through the critical temperature, and of successive anneals, are clearly described in the abstract and in the complete paper will be found a discussion of the value of varying percentages of carbon, sulphur, silicon, phosphorus and manganese and of subsequent heating to high temperatures. Picture-frame fractures are also discussed, and the author closes by exploding three popular theories with regard to malleable iron.

PRIOR to the time four years ago that research work was undertaken in the interests of the American Malleable Castings Association, the malleable-iron industry was in a more or less chaotic condition. There had been at least three years of serious business depression and ruinous competition as a consequence had been running its insensate course, but back of and beyond all this was the damning accusation of the engineer, that the material, except in the case of a limited number of concerns, was not only lacking in dependability, but of low strength when dependable. In railway-car fabrication particularly, the number of malleable-iron castings used had dwindled from a very large quantity per car to an almost insignificant number consisting mainly of unimportant details. Malleable cast iron was rapidly being replaced by the steel casting and in other directions as well the latter was encroaching on the legitimate field of the former and incidentally placing it in an exaggeratedly false position, for the reason that when substitutions were made the patterns were redesigned and made much heavier to accommodate the less fluid casting properties of that metal. When a steel casting failed, the attitude taken by the engineer was that the maker did not understand his business, that he was incompetent. On the other hand, if the broken casting proved to be made of malleable iron, the assumption in that case was not that the maker was incompetent, but that the material, *per se*, was unsuitable for the part. Under those rather distressing circumstances it was not strange that the malleable-iron founder stopped, looked and listened.

Formation of the American Malleable Castings Association

Among the various manufacturers of malleable-iron castings, at the time referred to were some twenty-five who were progressive enough to understand the benefits that accompany coöperation, and that one might better have an intimate friend with whom to compete than an enemy. These had formed an association that had been in existence some ten years and had as its objectives the exchange of ideas in the direction of business economy, improved works practice, the study of proposed foundry and factory enactments, the securing of more favorable insurance rates, the study of problems relating to cost, labor, housing and sanitation, and finally the forming of friendships that are the natural outcome of frequent and close personal contact. It is to these men that credit should be given for the renaissance of the industry. They decided to enlarge their field of action and, irrespective of cost, determined to go the full road along the lines of metallurgical research. They determined as well that every statement made as to progress would be conservative and accompanied by data that would be incontrovertible, which course they have followed to the letter.

When the research work was started, it was found that by far the majority of the members had no system of testing the quality of their product in order to ascertain its ductility, aside from the twisting and bending of a casting, or the bending over of test lugs attached to castings. Consequently there was no way in which the quality of product of one member could be compared with that of another. Mr. Benjamin Walker, who at the time was vice-president and general manager of the Erie Malleable Iron Company, of Erie, Pa., a number of years previous to this had devised for the purpose of testing the quality and uniformity of his product, what he called a test wedge. The wedge was 6 in. long by 1 in. wide, tapering from $\frac{1}{2}$ in. at its base to $\frac{1}{16}$ in. at its other end. His practice was to distribute a series of these wedges throughout the annealing oven, and at the conclusion of the anneal subject them to test—accomplished by holding the butt end of a wedge in a narrow-jawed tongs, placing it upright on an anvil, and striking its top end with a 6- or 8-lb. sledge. In this manner the thin end of the wedge would gradually curl up under these repeated blows, and it is apparent that the more blows the wedge would stand before fracture, the shorter would be the butt left in the jaws. The shortness of this butt he considered was a measure of the metal's ductility.

It was decided that an attempt would be made to standardize this test for adoption by the Association. With this end in view a machine was designed such that a weight of 21 lb. when raised to a height of 3.33 ft. above the top of the wedge (placed in position for test on the anvil of the machine) would be automatically tripped to deliver a fairly constant blow on the thin end of the wedge. The blows were counted, and for convenience the number delivered before rupture took place was recorded as the *blow efficiency* (assumed to be a measure of toughness), while the length of the butt (assumed to be a measure of ductility) was measured and expressed in terms of *butt efficiency*. These were arbitrary terms, understood by the members, and intended for their use only. Twenty blows has arbitrarily been chosen to correspond to a blow efficiency of 100 per cent, but at the present time we have numerous members whose wedges invariably test better than 30 blows. When a wedge fails to break at 30 blows without fracture, it is thrown aside, as it is obviously a waste of time to investigate it further.

[1] Consulting Engineer, Albany, N. Y.

Presented at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form, and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

Method of Submitting Test Bars and Reporting Tests

It was decided that tensile-test bars should be cast by all of the members, and that they be required to send to the consulting engineer one tensile-test bar and one test wedge from some one heat of each day's run. This made possible the ascertainment not only of the quality of each member's product, but furnished data through which a comparison could be made of the quality of the product of the membership as a whole. Equally important, it also served as a direct and positive measure of the progress that ensued from month to month. The dimensions of the tensile-test bar is exactly similar to that contained in the American Society for Testing Materials' specification for malleable cast iron. It is a round bar 12 in. long. The ends that go in the grips are each 3 in. long by $^3/_4$ in. in diameter, and gradually taper in a distance of 1 in. to the reduced section, which is $^5/_8$ in. in diameter and 4 in. long. At the end of each month a report is made of the results of the tests. This report is printed and distributed in the form of a bulletin. For convenience, and in order that the situation can be easily analyzed, the results are classified as shown in Table 1.

The members are classified into those who do railway work and those who do not. To the former is assigned a letter, and to the latter a number. Through this procedure each member can identify his record but not that of any other member, as all of the identification marks are known only to the consulting engineer.

In this manner it is possible to learn just how each member is progressing, and if it is considered by the Research Committee that his progress has not been as rapid as it should have been, the consulting engineer is requested to pay him a visit with the object of aiding him more quickly to better his condition.

Average Physical Properties Prior to Research

It is pertinent at this point to present in as fair and impartial a manner as possible a comparison of the physical properties of malleable iron manufactured within the past few years with that made in the period prior to 1913. Before entering into this matter the writer wishes to go on record as stating that any data in connection with the ultimate strength of malleable iron are valueless as far as serving to show its real worth, unless accompanied by information regarding the ductility of the metal as measured by the elongation. If one knows how, there is no difficulty whatsoever in making a metal of 85,000 lb. ultimate strength, provided ductility be sacrificed down to what would be represented by a 5 per cent elongation.

For many years the writer has had an unusual opportunity to learn either at first hand or on good authority what character of product most of the concerns made, and aside from one concern that had always enjoyed an enviable reputation for the uniformity and excellence of its product and another very large company whose plants were very painstaking in their methods of manufacture, the ordinary run of malleable iron was undoubtedly inferior. The tests made in this laboratory during the period mentioned do not number over three hundred. They do, however, represent the product of many different concerns. As some of the bars were of square section, some rectangular, and others round, it is plain that no uniformity existed in their dimensions. The latter vary anywhere from $^1/_2$ to 1 in. in diameter, while the former for the most part are 1 in. square and 1 in. by $^1/_2$ in. The great majority of these tests show that the ultimate strength was under [illegible] lb. per sq. in., while the elongations were for the most part under [illegible] per cent. There are instances of fairly high strength, slightly over 48,000 lb., while the highest elongations [illegible] 7 per cent in [illegible].

It happens that the writer has a record of tests made in 1911 on bars made by seven concerns that were deemed at the time to be unquestionably among the very best producers of malleable-iron castings. These founders were each asked to make 20 of the very best bars they could produce for test, 10 to be 1 in. in diameter, and 10 to be $^1/_2$ in. in diameter. In these tests the average ultimate strength of the 70 bars of 1 in. diameter is 39,882 lb., and the average elongation exactly 5 per cent. The lowest ultimate is 31,990 lb. and the highest 45,560 lb., the lowest elongation 1.7 and the highest 9.8 per cent. In the $^1/_2$-in. bars the average ultimate is 41,693 lb. and the average elongation is 5.5 per cent. The lowest ultimate is 33,600 lb. and the highest 47,430 lb., lowest elongation 1.2 and highest 6.3 per cent. Inasmuch as each of these seven concerns were informed that what was wanted was 20 test bars that would represent the very best product they could make, and inasmuch as these manufacturers were considered among the best of the producers, it would appear that the writer is warranted in assuming that the foregoing tests would represent a high rather than a low average.

Fallacious Theories of Malleable Iron

In Hatfield's Cast Iron in the Light of Recent Research, 1912, page 213, is a table containing the results of 14 tensile tests of bars 1 in. by $^3/_8$ in. in section. The bars run very uniformly and the material, while of low strength, is ductile. The latter should certainly be expected in bars that are but $^3/_8$ in. thick. The lowest ultimate strength is 38,820 lb. and the highest 45,700 lb., the lowest elongation 10 per cent and the highest 15.3 per cent. Under this table appears the following: "If attempts are made to increase the maximum stress obtained from such iron, the elongation would appear to have to be sacrificed, and to a considerable degree. In illustration of this the following records are given."

Maximum stress, tons per sq in.	Elongation, per cent in 2 in.	Reduction of area, per cent
18.9	12	9
21.1	13	8
24.0	9	8
26.5	7	5
27.8	5.5	3.5
29.0	5.0	4.2
34.3	3.0	2.5

Under this table the following words appear: "The cause of the increase in tonnage is the retention of increasing proportions of combined carbon. This combined carbon stiffens the material and incidentally reduces its ductility." The writer believes that he was the first to prove and furnish indisputable evidence as to the falsity of the statement that the ductility of malleable iron decreased as its ultimate strength increased. While Hatfield is correct in assuming that the ultimate strength is increased and the ductility decreased with an increase in combined carbon, the statements indicate clearly that he was, at the time at least, not familiar with the manner in which malleable iron can be obtained having the characteristics of high strength accompanied by high ductility. It can be stated, that in normal malleable iron as made today the higher the strength the higher will be the ductility, and in this particular this metal is unique.

In the Mechanical Engineers' Handbook, edited by Prof. Lionel S. Marks and published as late as 1916, appears the following by Dr. R. Moldenke: "These castings *should not be machined,* as the interior is not as strong as the metal at and near the surface. Tensile strength, 35,000 to 48,000 lb. per sq. in. European malleable cast iron, made by a somewhat different process, is not as sensitive to machining; the castings, which are thin only, are practically decarbonized in the annealing process; whereas in the American black-heart malleable iron only the skin is decarbonized, the metal adjacent for about $^1/_4$ in. partially so, and the central portions contain the full carbon percentage of the original hard white casting."

Improved Physical Properties Due to Research

Improvements have been made since the research work was started and Table 1 covers the physical tests for ultimate strength and elongation on bars received during the month of March 1919.

TABLE 1 ANALYTICAL EXAMINATION OF PHYSICAL TESTS FOR ULTIMATE STRENGTH AND ELONGATION ON TEST BARS SUBMITTED DURING MARCH, 1919

Limits of ultimate strength	Per cent of bars	Per cent elongation
Under 40,000 lb.	0.40	4.50
Between 40,000 and 42,000 lb.	0.88	6.86
Between 42,000 and 44,000 lb.	2.79	7.67
Between 44,000 and 46,000 lb.	6.47	8.13
Between 46,000 and 48,000 lb.	10.29	9.50
Between 48,000 and 50,000 lb.	17.16	10.09
Between 50,000 and 52,000 lb.	17.95	11.55
Over 52,000 lb.	44.06	14.67

It would be almost impossible to consider the figures in this record and fail to note that as the tensile strength increases, so does the elongation. These monthly records have been kept for four years and there is no exception to this rule. It will also be noted that only 0.40 per cent of the total bars received tested under 40,000 lb. per sq. in. As a matter of fact, only 10.54 per cent were under 46,000 lb., while 44.06 per cent stood over 52,000 lb. with an average elongation of 14.67 per cent. The best individual record showed an average of 59,681 lb. ultimate and 21.47 per cent elongation. The worst was 39,942 lb. ultimate and 4.20 per cent elongation. The latter record belongs to a member who but very recently joined the Association, and bears out quite well the thought that the writer has been endeavoring to convey.

The members who submitted bars classified under Railway Work were twenty-two in number. The average ultimate strength and elongation of test bars submitted by the eleven members having the highest averages are found to be 53,559 lb. and 15.56 per cent, respectively. Carrying through the same operation with the twenty-six members who are not thus classified, it is found that the average ultimate strength and elongation of these thirteen are respectively 52,327 lb. and 12.42 per cent. Taking the average of these twenty-four members, we find that the ultimate strength is 52,943 lb. and the elongation is 13.99 or practically 14 per cent. Lest our intention be misunderstood, it should be explained that our effort is not directed toward securing an increased ultimate strength and elongation so much as uniformity of product. The aim is to secure a product that the engineer will readily acknowledge possesses excellent physical properties, which vary but little from heat to heat. It may be of interest to state that from January 1, 1917, to March 31, 1919, the average ultimate strength of the test bars of the Association as a whole has been over 51,000 lb. ultimate and the elongation 12.50 per cent.

In considering the last statement the following facts should be taken into account. War conditions during 1917 and 1918 made it quite impossible to secure suitable pig iron and fuel, and it was solely and only through an intimate knowledge of the metallurgy of the process derived from the research work that made such a showing possible. It is therefore not unfair to assume that a still better showing could have been made had the times been normal.

At the beginning of our investigations an elongation of 10 per cent was considered to be an indication of a superior product. As our knowledge of the metallurgy of the process increased, accompanied by better air-furnace practice and annealing-oven conditions, the elongation particularly began to climb. An elongation of 20 per cent is not now looked upon as unusual; elongations of 25 per cent occur with considerable frequency, while we have had numerous bars that have run as high as 30 per cent and several of 31 per cent, which for an untreated cast-iron product we believe to be quite extraordinary.

Process of Making Malleable Castings

The process for making black-heart malleable castings involves two steps. The first step consists in making a casting in which the totality of the carbon will exist as carbide of iron, when the iron will have a structure shown in Fig. 1. (Air-furnace white iron has an average carbon content of but 2.40 per cent as against an average of 3.50 per cent in white pig iron.) The casting produced is white in fracture, hard and as brittle as glass. The second step consists in subjecting this white-iron casting to a heat treatment such as will serve to break up this hard carbide into its two original components, graphite and iron, both of which are very soft. Hence from a white-iron casting we can obtain through heat treatment one that possesses the properties of strength, toughness and ductility. Fig. 2 shows the structure of a normal well-annealed piece of malleable iron. The white ground mass is the carbonless iron (ferrite), while the dark continent is the carbon that precipitated out during the anneal. If Fig. 2 be compared with Fig. 1, an idea will be gained of the profound change effected in the structure during the annealing process.

The air furnace, in which the malleable iron is melted, consists essentially of a fire pot, hearth and stack. Some furnaces have a solid roof, the charge being "peeled in" through the charging door, but in the larger number of cases the roof is made up of bungs that can be removed during repairs and a sufficient number of them lifted off when necessary for the purpose of admitting the charge. While a few of the furnaces operate with natural draft, most of them use a forced draft of from 3 to 4 oz. pressure. Although oil is advantageously used for fuel in a few instances where its cost is not prohibitive, bituminous coal having a volatile combustible of from 25 to 35 per cent is the heating agent used by the majority. In order to burn the volatile products of the

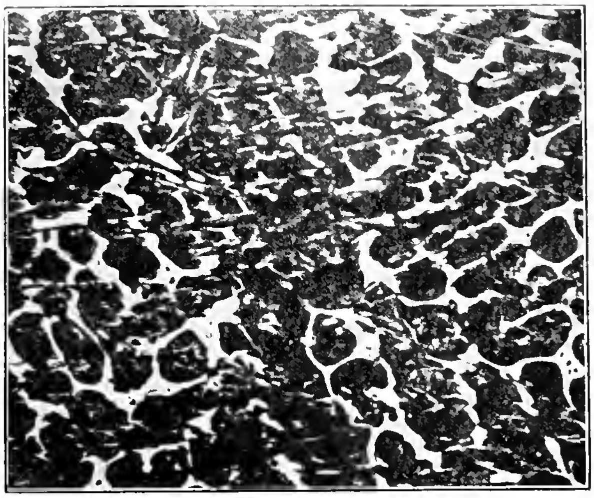


Fig. 1 Micrograph of Hard, White Cast Iron

coal, as well as the CO generated from it, when, as should be the case, a deep bed of coal is used, secondary air is admitted through a series of tuyeres or a continuous tuyere located far enough in front of the grate bridge wall and so inclined that the air will enter and be deflected about 15 in. from the base of the bridge. In this manner a maximum temperature of about 2800

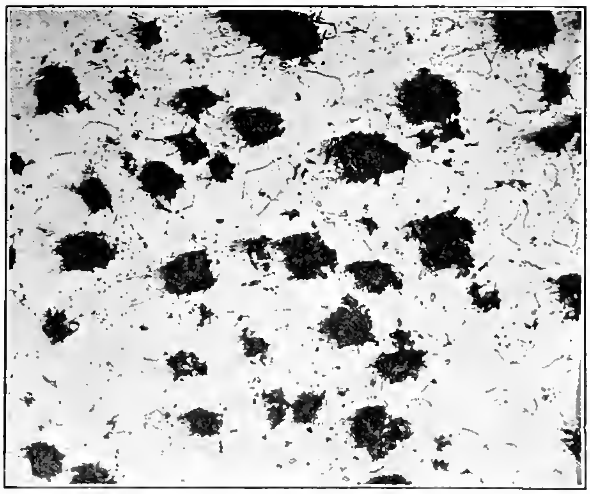

Fig. 2 Micrograph of Normal, Well-Annealed Malleable Iron

to 2950 deg. fahr. can be eventually obtained. Considerable time and thought have been expended in an endeavor to see if it would not be possible to regulate the amount of secondary air to just insure perfect combustion by the use of a CO_2 recorder, but it was found that the recorder would not act with sufficient promptness. The furnaces vary in capacity from about 7 tons to 35 tons. The best are very inefficient and in practice the fuel ratio is about three of iron to one of coal. The average practice does not exceed 2.5 to 1. In numerous cases waste-heat boilers are used and while this conserves heat, it obviously does not add to the furnace efficiency. The average furnace has a capacity of about 15 tons.

Annealing of Hard Iron

When a piece of air-furnace hard iron is gradually heated, many of its properties are changed. It will cease to be magnetic and the size of the crystals will be much finer than was the case under this particular temperature. It can be carburized beyond its original carbon content if packed in a carbonaceous material and held at this temperature for a sufficient length of time, while if packed in material that yields oxygen it can be decarbonized almost completely if the piece is thin. Also the carbide of iron can be broken up into its two soft constituents at this "critical temperature," or critical range, which for air-furnace hard-iron castings is in the vicinity of 1440 deg. fahr. It is the lowest temperature at which hard-iron castings may be successfully annealed. This statement must be modified by the further statement that in an oven under perfect control this temperature is the one that would be selected. In practice it would not be safe to adhere too closely to it, for the reason that should the castings while being held "at temperature" fall under the critical range, it would undo in large measure what had been accomplished above it. In the annealing of the castings one of the things to be avoided is oscillating temperatures, or temperatures alternating above and below the critical range. For this reason it is necessary to select a temperature some 100 to 150 deg. fahr. above the critical, say, 1550 deg. fahr., in which event, even if due to carelessness the temperature does drop a little, it will not be liable to fall to a dangerous point. There is another reason why this latitude is deemed essential and this has to do with the fact that in large ovens it requires considerable ingenuity to arrange flue openings, drafts, etc., in such a manner that the temperatures in all parts of the oven will be uniform, for which reason it is necessary to make sure that the temperature at the coldest corner is somewhat above the critical range, which will serve to safeguard oscillations in these locations.

Preparation of Castings for Annealing

In order to anneal the hard-iron castings that have previously been barreled or sand-blasted, chipped, gates ground off and inspected, they are packed in cast-iron pots where they are surrounded by an oxidizing packing. The packing has a dual function: to furnish oxygen through whose agency the castings will be decarbonized to the extent that is possible, and to avoid kiln warp—that is, prevent the castings from distorting. The usual packing consists of a predominating proportion of inert material, such as ground air- or blast-furnace slag, pulverized firebrick, etc., to which has been added iron oxide in some form, such as rolling-mill scale, hammer scale, etc. The pots, or stands are sectional and each comprises a casting which forms its bottom, upon which four or five sections are superimposed. Each section consists of a rectangular or circular "ring" about $1\frac{1}{4}$ in. thick and varying in size at different plants, depending upon the dimensions of the castings to be annealed, but averaging, if rectangular, about 14 in. by 24 in. by 14 in. high. In building up a stand a ring is placed on the stand bottom and then carefully filled with castings that are surrounded with packing. When the ring is completely filled it is hammered on the sides with a light sledge in order that the packing will run down and fill in all voids. The second ring is then placed upon the first one, and this is filled in the same manner, which procedure is followed until the stand of four rings is completed. The top ring is filled with castings only to about two-thirds of its height, for if they were brought to the top they would be exposed to the oven gases. Instead, the top third of the ring is filled with packing and this in turn is covered with an iron plate. The top, and all joints in the stand, are then mudded or luted in order to prevent the entrance of the oven gases, after which the stand is lifted up by the charging truck and placed in position in the oven.

The annealing ovens are usually of rectangular shape, and vary in capacity from 15 tons for a very small oven to 50 for the largest ones. Their average capacity is about 25 tons. The usual fuel is bituminous coal, but hard coal, powdered coal or oil are used. These ovens are being standardized and designed with a determination of securing uniformity of temperature throughout. The flues are not only being properly proportioned for the draft used, but the flue openings so dimensioned that the heat can be drawn to any part of the oven in amounts sufficient to equalize temperatures, while provision is made whereby they can be easily kept clean. In the plants of the Association practically all of the ovens are under pyrometer control, and equipped at a central station where it is possible at any moment to ascertain the temperature at the hottest and coldest part of any oven, while a master pyrometer is used as a check on those that are permanently located. Air-furnace and annealing-oven operations have also developed from extremely crude methods to intelligent control, and this in large measure accounts for the improvements in the uniformity of the product.

Length of Annealing Time and Temperature Limits

In annealing, the castings are brought "to temperature," that is, to 1550 deg. fahr. or as high as 1600 deg. fahr. if thought best, as rapidly as it is deemed they can absorb the heat. Too great a forcing of the heat during this period is avoided, for if it is done the rings expand much more rapidly than the material within them, which leaving a space between ring and contents will allow the packing to bleed down from the top toward the bottom of the stand, lessening the compactness in the upper rings. In average practice it takes about 48 hr. for the oven to arrive "at temperature." The temperature of anneal is then maintained for a minimum of 48 hr., the time recommended being 60 to 72 hr. Firing is then stopped and the oven sealed tight in order that the castings will not cool faster than from 8 to 10 deg. per hr. while passing through the critical range. To safeguard this very important detail, this rate of cooling is maintained until the pyrometers indicate that the oven temperature is less than 1100 deg., for on cooling, the castings are liable to be some 200 deg. higher than indicated by the pyrometer in the oven. After the temperature has been lowered to that point an opening is made in the front of the oven in order to allow it to cool more rapidly, for the reason that once the castings are at a temperature under the critical range no change can take place in their structural composition, so the only remaining precaution is to see that the castings do not cool so fast that internal strains can develop in them. From the foregoing, it can be readily seen that the average length of anneal occupies about seven days.

From theoretical as well as practical considerations the writer does not believe that there is a possibility of safely lessening the time for this operation by much more than one day without taking chances. He has designed an oven in which the temperature of 1600 deg. can be easily attained in 25 hr. and he is aware that when the composition of the hard-iron castings is such that the hard carbide is in its most unstable condition that even less than 48 hr. will suffice for the precipitation of the carbon, so that these two periods can be reduced somewhat, but danger is ever present if liberties are taken with the cooling through the critical range. In order then to safeguard the consumer as well as his own reputation, the manufacturer should make no serious attempt to shorten the anneal unduly. The annealing capacity should be such as to make the attempt unnecessary. If it is made, however, then the pyrometer element should be inserted directly into the center of the pot, placed for that purpose in contact with the side wall of the oven, in order better to determine when the castings have actually arrived "at temperature" and the moment when he can commence to record the time the temperature can be started on its downward course, which procedure will enable him to operate more closely and accurately.

From what has preceded it should be evident that the second step in the manufacture of these castings should not be known as an annealing process, but more appropriately as a conversion process. The dominant function of an anneal is to obliterate coarse crystallization or an unsuitable one, and replace it by the most suitable that it is possible to produce in the object treated and incidentally remove internal stresses. Annealing does not imply structural changes in the piece when cold, aside from grain size and grain refining. In the annealing of malleable-iron castings the dominant object is to convert white, hard iron, in whi

all of the carbon is combined, into a soft, tough, ductile iron in which no part of the carbon is in that state. In order to achieve this it is necessary to maintain for a sufficient length of time a temperature just in excess of the critical range, which, as has been pointed out, coincides closely with that at which grain refining occurs, so it happens that during the conversion both objects can be practically attained.

Appearance of Fracture of Test Pieces

It requires an extended experience before one can tell from the fracture of the iron what may have caused its abnormal condition, which is one direction in which great progress has been made. When a normal, well-annealed piece of malleable iron is subjected to a steady, direct pull in a testing machine, a point

Fig. 3 Fractures Showing Width of Decarbonized Rim

is reached at which the crystalline grains of which it consists are elongated permanently, the stretch continuing until fracture takes place. If the fracture is examined it will be seen that the grains have elongated into finely pointed spines which gives what is called a "tooth" to the fracture. When light falls obliquely on such a fracture, there is produced a play of colors that yields a sheen caused by a reflection from the points and sides of the spines and the shadows that fall between them. As the grains in

Fig. 4 Micrograph of Specimen with 0.33 per cent Silicon and 0.089 per cent Manganese

the decarbonized rim are more ductile than the rest of the metal in the section, they will elongate to a greater extent, and if the fracture is held in certain directions to the light, the width of the decarbonized rim can be seen by contrast, its color appearing under those conditions a little lighter than the rest of the section. (See Fig. 3.)

This explanation is made and entered into because such a rim or border must not be confused with and mistaken for the character of fracture that has a well-defined frame, that is, a border having not only a sharp line of demarcation between it and the core of metal which it surrounds, but an appearance wholly distinct from it. If the writer were asked to pass judgment as to the quality of a piece of malleable iron, based upon either the appearance of its fracture, or what would be shown by a polished and etched section under magnification, he is positive that he could render a more reliable opinion in the case of the former than would obtain in the case of the latter. The reason lies in the fact that even in a non-ductile product it is possible to have an absolutely normal structure, one which consists of a matrix of ferrite or carbonless iron; throughout which are uniformly distributed nodules of free carbon, such as shown in Fig. 1, while if the fracture is as has been described, a normal structure at least can be predicted. If the ferrite is not ductile, then the crystalline grains will not elongate, with the result that we obtain a structural appearance that would be interpreted by those not familiar with the facts as belonging to a piece that had been insufficiently annealed. It has already been stated that when the silicon is too low a steely fracture will result, and also that the metal is liable to be unsound. In making this statement the writer is assuming that the silicon is low, not because too little was used in the charge, but due to excessive elimination in the air furnace.

In such cases the low silicon will be accompanied by low carbon and manganese. In Fig. 4 can be seen the structure of a piece that had a silicon as low as 0.33 and a manganese of 0.089 per cent. The fracture of this piece was uniformly bright and coarsely crystalline. It had no frame. The structure consists of a matrix of pearlite and throughout it are distributed particles of undecomposed hard carbide (cementite) and small well-rounded nodules of graphite, or temper carbon, as that carbon is called

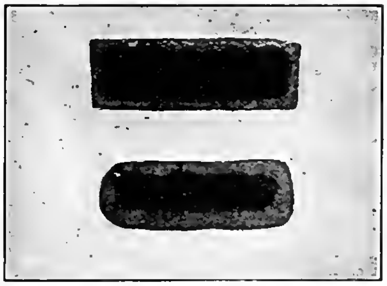

Fig. 5 Picture-Frame Fracture in Low-Silicon-Carbon-Manganese Specimen

which separates out during an anneal. The casting from which this piece was taken was in an oven in which castings of correct composition annealed perfectly, and the presence of the particles of undecomposed carbide simply means that the anneal was not carried on for a sufficiently long time for this character of product. The casting, however, would have been very inferior even if all of the carbide had been broken up.

Picture-Frame Fractures

Very frequently certain low-silicon-carbon-manganese compositions will yield what are known as picture-frame fractures, such as are shown in Fig. 5, which are typical and have the following composition: Silicon, 0.54; phosphorus, 0.162; sulphur, 0.053; manganese, 0.108; total carbon, 2.01. This piece when polished and etched showed the following characteristics: a decarbonized surface border, an inner ring of coarsely laminated pearlite, and within this a core corresponding in structure to that of normal malleable iron. Fig. 6 shows the decarbonized border surrounding the pearlite ring, Fig. 7 the structure of the pearlite ring, and Fig. 8 the core within the pearlite ring. It is the presence of this ring of pearlite whose ductility is so much less than that of the metal in either the decarbonized border or core that produces on fracture the sharp line of demarcation between frame and core. While in this particular fracture the frame is fiery bright and finely crystalline and the core black, there are picture-frame fractures that show various color characteristics of frame and core, but it will be found that invariably the frame has its pearlitic ring of greater or less breadth. The pearlite is not always coarsely laminated, but as a rule has the appearance and con-

sists of an amount of pearlite that would correspond to a 0.35 per cent or 0.45 per cent normalized carbon steel.

If the sulphur in the hard iron is unduly high and particularly if not well balanced by the manganese, the castings will almost invariably show a picture frame on the fracture, and especially is this true if the temperature of anneal is too high for such a composition. If the manganese is too high and not well balanced by the sulphur, the same result will follow.

While time is not available to enter into a full discussion of what has been discovered in regard to picture-frame fractures, there are some points that can be recorded. There are some compositions that unquestionably have frame-producing tendencies. These compositions will not produce a frame when annealed in an atmosphere that is not oxidizing. The surface structure of the hard iron has nothing to do with the problem as the writer has had 1/4 in. ground off of one side of hard-iron samples and upon annealing the frame was in evidence equally on all sides. It is believed that the following facts are pertinent to the situation: Not only do certain compositions affect the ductility of ferrite, but the same is the case with a pearlitic structure. We can have ferrite that will elongate into very long spines and ferrite that will fail to elongate at all. We can have a pearlitic grain that can be ductile and those that are not. The foregoing is stated because the writer believes that whether or not a frame will be produced in the fracture depends upon the breadth and ductility of the pearlitic ring, because a slight pearlitic ring can be present within a decarbonized border without a picture-frame fracture being produced. It is his belief that whether there will be a pearlitic ring or not depends upon the rate of surface decarbonization, as compared with the rate at which a dissociation of the cementite takes place. When conditions are such that there will exist a region between the decarbonized surface border and the core that will have a carbon content of about 0.90 per cent, equilibrium seems to be established in this region, and if any carbon passes from this region to the decarbonized border it is replenished by carbon from the core.

FIG. 6 MICROGRAPH OF DECARBONIZED BORDER

FIG. 7 MICROGRAPH OF PEARLITE RING

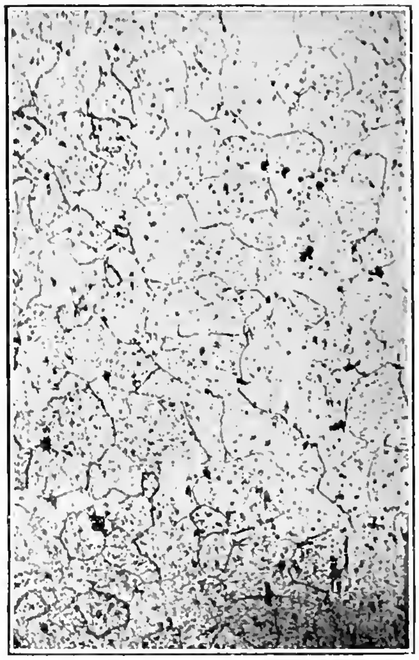

FIG. 8 MICROGRAPH OF CORE WITHIN PEARLITE RING

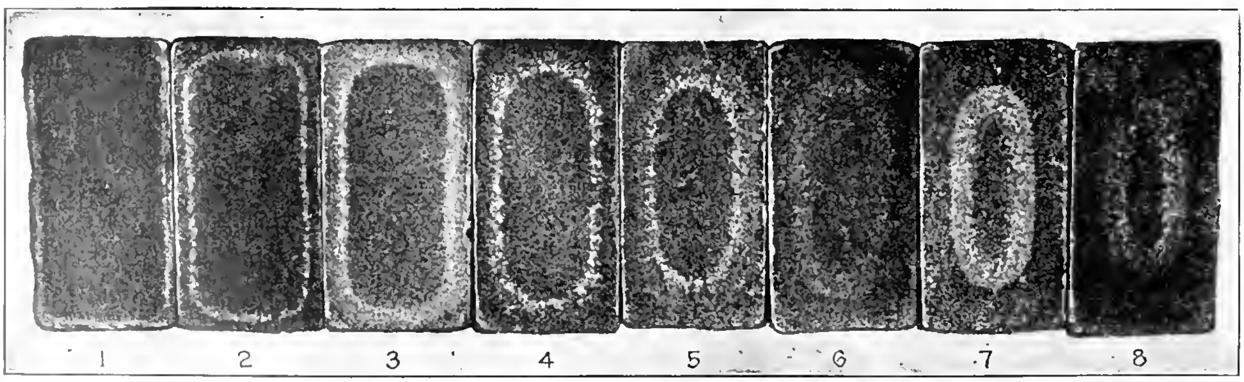

FIG. 9 THE PEARLITIC RING IN SUCCESSIVE STAGES OF ANNEALING

THE PEARLITIC RING

The writer believes that such is the case, and is of the opinion that perhaps the samples shown in Fig. 9 may have a bearing on the case. A well-annealed bar was cut into eight pieces. A section from the first piece was polished and etched, and the other pieces all packed together and given another anneal. The second specimen was then prepared like the first. The remaining six were then given a third anneal, and the third piece polished. As this procedure was continued, it follows that the eighth bar had

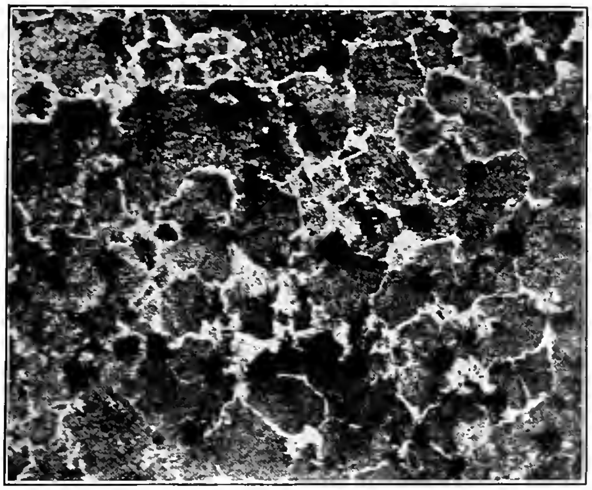

Fig. 10 Micrograph of Malleable Iron of High Ultimate Strength

eight separate and complete anneals. It will be noted that its very faint pearlitic ring which shows whitish and very faint in the once-annealed bar, is very distinct and well defined in the second and that it is wider and further in toward the center. It will be seen that with each anneal the pearlitic ring has widened and has a smaller periphery. As it was found that with each anneal the total carbon content decreased, it is plain that once the pearlitic ring has formed, it does not act as a seal for the passage of carbon from core to surface and that the width of the pearlitic ring is built up and added to more quickly from the core than it is robbed of carbon by the decarbonized border. The matter can be summed up as follows: If conditions are such that a region containing about 0.90 per cent or less carbon is formed, this region while permitting carbon to migrate or diffuse through it will at the same time be incapable of having its carbon precipitated. Under proper conditions the region can alter its position and increase in extent. For such a region to have a start it is essential that there be a very substantial difference in carbon content in two parts of the section.

Structure of High-Strength Malleable Iron

Malleable iron of very high strength accompanied by a ductility that can be considered good enough for certain purposes, has already been mentioned. While no effort has been made to exploit this product as yet, it would appear to the writer that there is a very large field in which it could be used to advantage. In Fig. 10 can be seen the structure of a sample that stood an ultimate strength of 84,000 lb. and had an elongation of 5.20 per cent. This material can be made with uniformity and it is believed from experiments that have been under way for some time that a 90,000 lb. ultimate and a 10 per cent elongation might be uniformly maintained. It will be noted that the structure consists of a ground mass of pearlite, in which are more or less uniformly distributed nodules of temper carbon. The structure readily explains why the product is of high strength.

Effects of Heating Malleable Iron

As it is frequently necessary to heat the finished product for the purpose of straightening it, for galvanizing and other purposes, it may prove instructive to see what happens when an annealed piece of malleable iron is heated up to and beyond the critical range. Ten pieces were cut from a normal, well-annealed malleable-iron bar. Fig. 11 shows the structure of this bar at 200 diameters. The pieces were then placed in an annealing oven that could be controlled with great accuracy. When the pyro-

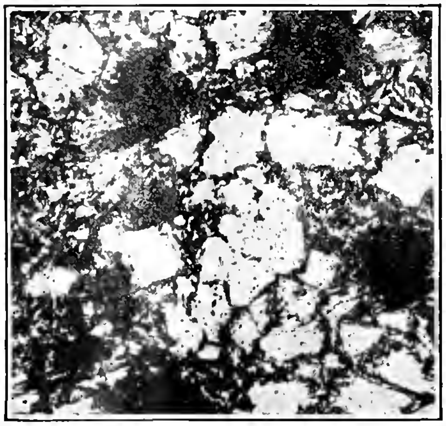

Fig. 15, 1500 deg.

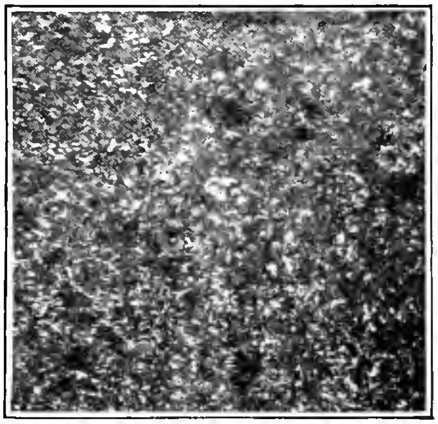

Fig. 16, 1675 deg.

Figs. 11 to 16 Micrographs Showing Effect on Structure of Heating to Various Temperatures

meter registered 1250 deg. fahr., one piece was withdrawn and allowed to cool in the air. When the temperature reached 1300 deg. fahr. another piece was withdrawn. The other pieces were withdrawn at temperatures of 1350, 1400, 1450, 1475, 1500, 1550, 1600 and 1675 deg., respectively. Fig. 12 shows the structure at 1400 deg., Fig. 13 at 1450 deg., Fig. 14 at 1475 deg., Fig. 15 at 1500 and Fig. 16 at 1675 deg. All of these micrographs were taken at a magnification of 200 diameters. It is apparent that no change has taken place in the structure up to 1400 deg., but that somewhere between 1400 and 1450 deg. the structure starts to alter in appearance. An examination of Figs. 13 to 16 shows that increased amounts of pearlite result as the temperature is increased, and that in Fig. 16 nearly all of the temper carbon has been dissolved. It follows that for straightening, brazing and other operations that necessitate the heating of a malleable-iron casting, the temperature used should be well under 1400 deg. fahr.

Common Fallacies

The fallacies that have been handed down and accepted by many of the engineers and consumers as true are numerous, but the following only will be touched upon as they are the most important:

a The strength of malleable iron lies in the skin. When it has been removed the remainder of the metal is found to be very inferior and not dependable.

b During the anneal, the elimination of the carbon is confined to the surface, and the amount removed from the rest of the section is inconsequential.

c When the section of a casting exceeds 5/8 in. in thickness, it cannot be annealed throughout.

Concerning item *a*, the data in Table 2 will prove of value.

TABLE 2 TESTS OF MALLEABLE-IRON BARS WITH DECARBONIZED SKIN REMOVED

Mark	Ultimate strength, lb. per sq. in.	Per cent elongation in 2 in.
12-2-1	52,084	17.50
12-3-1	47,182	10.00
12-3-2	51,107	17.50
12-4-1	56,732	14.00
12-5-1	46,482	7.00
12-5-2	52,246	23.00
12-6-1	47,889	19.00
12-7-1	48,080	18 00
12-7-2	49,640	18.00

Nine regular test bars were machined until the decarbonized surface was removed. These bars were all from different heats and marked as indicated in the table.

As the writer did not have duplicates of these bars, he was unable to make a comparison between the machined and the bars as cast and lacked time to run through a set for illustration, but the experiment should be unnecessary in any event in view of the above. It is obvious and must be acknowledged that the metal in the decarbonized skin is more ductile than the core, so when a bar fails it must be conceded that it is the core that has parted first, for the reason that the metal in the skin has not at the instant of fracture reached its maximum elongation. Aside from the foregoing we have the practical evidence that presents itself in the case of the automobile industry in which thousands of tons of machined malleable-iron castings are used annually on parts that receive in service great abuse, such as wheel spindles, etc. On the other hand, the writer not only admits that when the skin is machined off some malleable-iron castings the remaining part is worthless, but admits as well that the castings would be such with the skin on. This, unfortunately, will continue to be the case until the purchasing agents cease to shop around and make contracts with price as the basis rather than quality.

Taking up item *b*, the writer can, without encumbering this paper with the large amount of data he has on the subject, prove the falsity of this contention. In the figures quoted in Table 3 of the complete paper for bars of over 52,000 lb. ultimate strength and over 20 per cent elongation, there will be noted two bars, one of which has a carbon content of 0.72 per cent and the other of 0.82 per cent. Aside from this there are fourteen with a carbon content of 1.50 and under. It has already been pointed out that the carbon in the hard iron must be kept up to a certain figure, failing which the castings will not only misrun, but contraction cracks will spoil them. If we assume, in the case of the first two bars referred to, that the carbon was reduced by one-half, then in the bar that had but 0.72 per cent carbon, the carbon in the hard iron from which it was cast must have been 1.44 per cent, and we all know that it would be almost impossible to run such work, say nothing about subsequently annealing it. In a 5/8-in.-diameter annealed bar such a low carbon content is unusual but it proves the point that is being made nevertheless. The writer has polished the section of two 5/8-in.-bars and has photographed them at about seven diameters. One of these is shown in Fig. 17 and will furnish a fairly good idea as to how the carbon is distributed throughout the section, and indicate that the carbon does not vary by uniform gradation from surface to center, but in one region can vary slightly from what it may be in another. This does not signify that in the regions of highest carbon content the carbon has not been lowered through diffusion into its contiguous region, for many investigations have shown that this is just what does happen.

Item *c* can be disproved in a few words. We know that in order to break up the hard carbide in white iron it is simply necessary that the casting be not only heated until the iron is in an austenitic condition, but maintained at that temperature for a certain interval of time. To state that thick castings of white iron cannot be annealed is to state that they cannot be brought to a uniform temperature throughout and maintained at that temperature. Such a claim would be an absurdity.

Fig. 17 Bar Magnified Seven Diameters to Show Carbon Distribution

For the benefit of those who labor under the impression that malleable iron is a product unsuited for any but small castings, the writer would say that he has a photograph of a casting 5 ft. long, 23 in. high with some of its sections 3 in. thick. The metal when well made, can also withstand great abuse. Irrespective of how good the metal may be, as shown by physical tests on bars and wedges, patterns are often furnished so outrageously out of proportion that the good qualities of the metal can easily be destroyed and too frequently the metal is blamed when the design is at fault. These troubles are overcome as far as possible by a thorough study of the best method of gating the casting, in order that no evidence of shrink will be present in any part. Research has made considerable advance in this direction and well-placed, well-proportioned shrink heads are now generally used. Not infrequently, in the case of such castings as the ones referred to, the sprue, runners and heads weigh about as much as the casting.

Committee on Aims and Organization

Tentative Report of the A. S. M. E. Committee, Dealing with Society and Professional Activities and Relations of the Engineer to the Community

FOLLOWING the business meeting at the Spring Meeting of The American Society of Mechanical Engineers on Monday, June 16, the report of the Aims and Organization Committee was presented by its chairman, Louis C. Marburg. This report evoked so much interest that sessions for its discussion were required on three different days. The report is published herewith both in its original form and with the resolutions as amended at the meeting. The report was discussed section by section, and the synopsis of discussion herewith reported is grouped under the several headings to which it belongs.

In presenting the report, Mr. Marburg stated that the committee considered it as tentative and in making its recommendations felt very strongly that it should avoid giving too many details but should state, instead, its views along lines of broad principles. The chairman of the meeting, President Cooley, then called upon Prof. Dexter S. Kimball who said the committee desired it to be understood that the report was not the work of a small body of men anxious to tear down something simply because it existed as a committee; nor did they want to introduce radical ideas into the report simply because of their own points of view.

As nearly as he could place his finger on the origin of the documents, it started with the Committee on Meetings and Program of which he had been a member for some years. In the work of that committee it was necessary to arrange for papers and it had been difficult to get unanimity of opinion as to what the aims of the Society really were and what kind of papers should be presented.

He called attention, however, to the fact that the A. S. M. E. was not alone in the matter and that every society of note in the country is now wrestling with the same problem, every university is wrestling with it and every technical school. The work of the Aims and Organization Committee had been sub-divided in the way noted in the report, with the committee split into three groups and a chairman appointed for each; the work had been conducted by sending out questionnaires from which a great mass of information, criticisms and suggestions had been received. That matter was boiled down and so arranged that the committee as a whole could pass upon it, and constituted, in effect, a composite opinion of a large number of members. A great deal of the work was done by correspondence and recently the three sub-committees met in conjunction and each framed recommendations which were then submitted to the committee as a whole and endorsed by the committee.

RECOMMENDATIONS OF THE COMMITTEE ON AIMS AND ORGANIZATION

Text of the Report as Modified by Vote of the Meeting, Together with the Committee's Wording Where Changes Were Made

The Professional Activities of the Society

OUR discussion of the professional activities of the Society undertaken for the benefit of mechanical engineers led to the opinion that this work can well be strengthened in practically all its branches. The specific recommendations for the development of professional activities follow:

Adoption of Standards

2. RESOLVED: that it is the sense of this meeting that Section C-49 of the Constitution of The American Society of Mechanical Engineers be amended so that the Society may approve and adopt such professional reports and standards as shall from time to time be presented to it. [The foregoing resolution was adopted in place of the resolution printed by the Committee, which was the same except that it did not include the words "That it is the sense of the meeting."]

3. The purpose of this change is to permit the Society to adopt an active progressive policy in place of the present passive policy.

Professional Features of General Meetings

4. RESOLVED: that continuous tenure of membership on the Sub-committees of the Meetings and Program Committee be discontinued, that the classification of engineering activities be retained and extended, and that the means and methods of collecting information under this classification be enlarged and improved.

5. The purpose of these changes is to get better papers of broader scope.

6. RESOLVED: that all Sub-Committees of the Committee on Meetings and Program be appointed for limited terms, all memberships to expire automatically at the end of said terms, but a sufficient number of experienced members should be selected, when reconstituting any such committee, to secure continuity of policy.

Research and Standardization

7. RESOLVED: that the Society, in addition to the work it is now doing in aiding, recording and publishing matters pertaining to research take a more active interest in this field by the following methods:

a. By increasing the appropriations made from its own funds to further research and by obtaining from other sources funds to conduct research.

b. By determining and formulating problems requiring investigation, and by securing men and facilities to solve these problems.

8. RECOMMENDED: that the Society establish the policy of formulating and adopting engineering standards, but that, in general, these be limited to elements, and that the standardization of combinations be left to organizations devoted to special industries.

9. RECOMMENDED further: that all such standards be considered as progressive standards and not as ultimate ones.

Industrial Engineering

10. RESOLVED: that Industrial Engineering is a major subject for consideration by the Society, and should be placed on a par with all major technical subjects.

Education and Special Training

11. RESOLVED: that the Committee heartily approves the work now being done in connection with the Student Branches and technical schools of higher grade in general, and recommends that this work be strengthened as much as possible.

12. RESOLVED: that in the opinion of the Committee, the Society is not realizing its opportunities in connection with industrial education below the grade of college work, and recommends the formation of a strong committee to take up this activity vigorously.

13. The reason for this recommendation is found in the need of the engineer for trained subordinates and industrial workers.

14. *Professional Groups.* The By-Laws of the Society provide for professional sections, under a clause of the Constitution (C52). Several requests for such sections, including an Ordnance

Section, a Power-Plant Section, an Automotive Section and a Petroleum Section, have recently been received.

15. Recommended: that a standing committee on Professional sections be constituted, analogous to that on Local Sections.

Development of the Society's Publications

16. Resolved: that the Committee on Publications and Papers be encouraged to publish in Mechanical Engineering (The Journal) matter of broader scope, including papers and articles that have not been presented at any meeting of this Society, news items of engineering interest, and the information of general interest now presented in Bulletins.

[In the resolution before amendment the resolution read: Resolved: that Mechanical Engineering (The Journal) be made a weekly publication at the earliest possible date, and that the Committee on Publications and Papers be encouraged to publish matter of broader scope, etc. (as continued above).]

17. Resolved: that the Committee on Publications and Papers be requested to study the possibility of a substitute for the present expensive method of publishing the Transactions, reporting any plan developed at the Annual Meeting.

[In the resolution before amendment, the last clause read "presenting any plan developed to the members of the Society for letter ballot.]

18. Resolved: that the Society publish, as soon as practicable a Handbook of Mechanical Engineering Data.

Absence from Committee Work

19. Resolved: that the Council formulate and put into force such rules as will cause membership on any Council or Committee of the Society to terminate automatically on account of absence or neglect, either willful or due to force of circumstances.

Engineering Societies' Employment Office

20. Recommended: that the present Joint Employment Bureau in New York be retained and its activities be expanded and made more efficient.

21. Recommended further: that the name of employment officials be secured especially through the local sections, and that these officials be supplied with lists of men.

Code of Ethics

22. Resolved: that it is the sense of this meeting that a short Code of Ethics of broad scope, general character and positive rather than negative injunction, be prepared and that the same be enforced vigorously.

22*a*. Resolved: that a committee of five or Code of Ethics be nominated by the President and confirmed by the Council, who shall report back to the Society at the Annual Meeting.

[The foregoing resolution was adopted in place of the following resolution presented by the Committee:

22. Resolved: that the present code of ethics of our Society be abolished as unnecessary and unenforceable.]

Relations of the Mechanical Engineer to the Community

(Note. In order to avoid confusion, the term "technical societies" will be used to refer to the four Founder Societies and such others as confine their activities to specific professional or technical phases of Engineering. The term "general engineering societies" will be used to cover the federation—local, state or national—on such basis as may develop, of the various technical societies, their sections and others concerned with engineering.)

23. In the opinion of the Committee, the relations of the engineer to municipalities can best be cultivated through group activity, proper groups being the local general engineering societies which should include engineers of all classes. In state affairs, these relations may be developed through a coalition of such local groups into state associations, while matters of general and national interest may be handled by a national organization of such local, district and state societies. Such a system of societies is considered below.

24. The entity of the various local sections of the technical societies should be preserved, but they should form part of the local general engineering societies. In dealing with public affairs, their members should act as members of the general engineering society and *not* of the technical section.

25. Distinctly technical work such as the formulating and publication of safety codes, the fixing of standards, etc., should be done by those technical societies which, jointly or severally, are concerned with the particular subject: e. g., the Boiler Code by The American Society of Mechanical Engineers, wiring standards by the American Institute of Electrical Engineers, etc. But the agencies for bringing about their general adoption and legalization should be the general engineering societies local, district, state and national.

26. As embodying the above, the Committee presents the following resolutions:

27. *Whereas:* The Committee on Local Sections has been engaged in promoting coöperation between Local Sections of the American Society of Mechanical Engineers and other local engineering organizations, and

28. *Whereas:* it is desirable that this coöperation be encouraged and further vigorously developed not only among local but also among national engineering organizations, and

29. *Whereas:* engineering solidarity should be established to enable the profession to more effectively serve the community at large, therefore be it

30. Resolved: that the policy heretofore pursued by the Committee on Local Sections is heartily endorsed, and be it

31. Resolved: that the Council of the Society should actively encourage further development of coöperation both in local organizations under the leadership of local engineering societies, and in state or territorial groups, which can effectively handle state or territorial problems. This coöperation to take such form as will most readily lend itself to national coöperation, and be it

[In the resolution before amendment the words "as in Philadelphia or Cleveland" followed "local engineering societies," and the words "as in Minnesota or Ohio" the words "territorial problems."]

32. Resolved: that there should be created some agency of a national character through which the coöperation of local groups, state groups and national societies can be secured for purposes of national scope. This agency to be composed of representatives of the members of local groups, state groups and national societies. It should be an organization capable of speaking in the name of the profession, and be it

[The last sentence of the foregoing resolution before amendment read: "It should be an independent organization, fully empowered to act and capable of speaking in the name of the profession, and be it"]

33. Resolved: that The American Society of Mechanical Engineers should collect and publish in pamphlet form the various modes of coöperative organizations used in different localities, thus enabling each group of organizations contemplating coöperation, to more readily select the method best adapted to their local conditions.

34. Acting through the organizations above suggested, service to the community may best be promulgated along the following lines:

35. *Legislation.* Protection of Health, Life and Comfort—By securing the introduction of safety codes, of which the Boiler Code is an example, by securing the adoption and enforcement of measures for smoke prevention, the inspection of elevators, and the use of safety methods and appliances in the industries, etc.

36. Production, Distribution and Sale of Commodities—By the establishment of standards of size, strength and quality of manufacture of products, of standards of material, and standard methods of testing materials and performances.

37. Industries, Utilities and National Resources owned or controlled by Communities—By initiating and guiding legislation for their operation, development and conservation, and particularly by developing and securing the adoption of uniform systems of accounts and reports for public utilities, *both* privately and publicly owned.

38. Legislation for Protecting the Public in Engineering Affairs—By action to secure uniform State and Federal laws for the registration and certification of professional engineers whose work involves the public health, safety and well-being.

39. *Administration.* Placing Engineers in Public Positions requiring Engineering Training—By efforts to bring about the appointment rather than the election of engineering officials, and to secure the appointment and retention of the best grade of engineers in the public service; and also by cooperation with such civic bodies as the Civil Service Reform League.

40. Coöperation with Engineers in Public Positions—By encouraging such engineers to become members of the local general engineering societies, and by giving them the support of such societies when political or other influences seek to interfere with the proper exercise of their functions. The reports of such engineers may be made profitable and mutually helpful subjects of discussion and review by such societies.

41. Selection of Engineers to Meet Public Emergencies—The organization of the profession through general engineering societies seems to offer the best means for the prompt direction of the talent and efforts of engineers classifies as to their special abilities and experience, would be helpful in this connection.

42. *Enforcement of the Law.* By action in conjunction with other civic bodies rather than independently.

43. *Public Opinion.* By an active, but dignified program of education in the public press. This should be free from objectionable advertising and of a character which would broaden the public knowledge of, and its appreciation for, engineering achievements.

44. *Industrial Relations.* By active participation in the solution of the industrial problems now before us.

45. In his Presidential address before this Society in 1882, the second year of its existence, Dr. Thurston said:

> In singular and discreditable contrast with all the gain in recent and current practice in engineering, stands one feature of our work which has more importance to us and to the world, and which has a more direct and controlling influence upon the material prosperity and the happiness of the nation than any modern invention or than any discovery in science. I refer to the relations of the employers to the working classes, and to the mutual interests of labor and capital. It is from us, if from any body of men, that the world should expect a complete and satisfactory practical solution of the so-called Labor Problem. More is expected of us than even of our legislators. And how little has been accomplished?

46. Mr. Marburg in the progress report of this Committee in December last, said:

> Among all the educated classes, the engineers are the one group in closest touch with labor. It is the part of wisdom and our duty to Society to try to understand the strivings of the working classes for our own benefit and to interpret them to the rest of the community. If the British Labor Party has been able to frame a reconstruction program and to produce a document commanding the admiration of most thinking men, surely it behooves us, the engineers, the men of whom, on account of training and experience, industrial leadership might reasonably be expected, to discuss the mighty problems now before us.

47. The engineer was the first to attempt a definite solution of the problems involved. He has contributed most of the constructive work which has been done to date, and on him rests the principal burden of an adequate and constructive solution.

48. The political autocracies of the world have been overthrown, but industry remains to be democratized. Labor is not going to be contented with its present subservient and limited condition, and its discontent will not be ameliorated by welfare work or other manifestations of benevolent despotism. The engineer stands between opposing interests, frequently between extremists, the self satisfied obdurate employer who still regards labor as a chattel on the one hand, and on the other the radical laborite who would confiscate all forms of property. With his analytical habit of thought, his experience in estimating and directing physical and industrial forces, he must devise industrial methods which will insure greater and more efficient production and a more equitable distribution of it, and he must take the lead in their adoption.

49. As outlined above, action in public affairs should be through the general engineering societies, but discussion is distinctly within the province of our own Society. The Committee therefore presents the following resolution:

> 50. RESOLVED: that the Society should enlighten its membership in regard to all Federal, State and Local problems which should interest engineers, and in the solution of which their experience and training may be helpful.

Election of Officers

51. *Regular Nominating Committee for Elective Offices.* The Council referred the recommendations of the Committee on Local Sections and the Committee on Constitution and By-Laws on the manner of election of the Regular Nominating Committee by the voting membership to the Committee on Aims and Organization.

52. The plan of the Local Sections Committee was to utilize the organization of the local sections to affect this election, while that of the Committee on Constitution and By-Laws proposed dividing the country up into 15 districts of approximately equal membership and having one member on the Committee from each district.

53. The Committee on Aims and Organization carefully considered both the relative merits of the two plans and passed the following resolution:

> 54. RESOLVED: that it is the sense of the Committee on Aims and Organization that the regular nominating committee for the election of officers, as provided for in C48 of the Constitution, be composed of a member from each local section; provided that each voting member of the Society be assigned to some local section by the Committee on Local Sections exclusively for the purpose of electing a nominating committee member, and provided further that members of the Nominating Committee shall be elected annually for one year, and no member shall be eligible for more than two consecutive terms.

Time of Election

> 55. RESOLVED: that the Committee on Constitution and By-Laws be requested to prepare such changes in the procedure for the annual elections of officers as will permit the declaration of their election by a considerable time to be determined by the Council. [In the resolution before amendment the fourth line read "their election by November first."]

Information on Candidates

> 56. RESOLVED: that biographical sketches of all candidates for office in the American Society of Mechanical Engineers should be sent out with the ballot for election to office of the Society.

Respectfully submitted,

L. C. MARBURG, *Chairman*

DISCUSSION OF REPORT OF THE COMMITTEE ON AIMS AND ORGANIZATION

Adoption of Standards

The first resolution considered was as follows:

> 2. Resolved: that Section C-49 of the Constitution of The American Society of Mechanical Engineers be amended so that the Society may approve and adopt such professional reports and standards as shall from time to time be presented to it.

The section of the Constitution referred to (C-49) now reads: "Reports of such committees (Professional Committees) may be accepted by the Society and printed in the Transactions, but shall not be approved or adopted as the action of the Society."

The discussion of this resolution was mainly in the direction of clarifying ideas as to present procedure in passing upon reports, and as to the necessary changes in this practice in the event of the resolution going into effect. Secretary Rice explained that reports are now considered as recommended practice, ordered printed by the Council. The committee's names are affixed to each report so that a person reading a report can form his own opinion as to its authoritative character. Under the new conditions, instead of using the Society simply to give voice to the report, it would have the official approval and stamp of the Society.

Dexter S. Kimball said that the Aims and Organization Committee considered this one of the most important resolutions presented and that it reflected the suggestions received from a large number of members of the Society. If the Society believes in the Boiler Code, for example, why not say so and stand back of it? Alex Dow favored the present practice by which a standard is regarded as a gospel which may well be followed, rather than a creed which must be subscribed to. S. N. Castle held that an adopted report should be considered as carrying the minimum requirements rather than the maximum; an engineer could make his specifications as much better than called for by a report as he saw fit.

Major Fred J. Miller pointed out that the resolution as presented was in effect a proposition to amend the Constitution and that the vote should not be to that end, for which ample provision is made in the Constitution itself, but for the purpose of expressing approval or disapproval of the practice recommended. Past-President Jesse M. Smith accordingly proposed the following modification of the resolution, in which form it was adopted:

> Resolved: that it is the sense of this meeting that Section C-49 of the Constitution of The American Society of Mechanical Engineers be amended so that the Society may approve and adopt such professional reports and standards as shall from time to time be presented to it.

Professional Features of General Meetings

Arts. 4 and 6 of the report proposing that continuous tenure of membership on the Sub-Committees of the Meetings and Program Committee be discontinued and that such sub-committees be appointed for limited terms only, formed the subjects for discussion under this heading and were approved.

Dexter S. Kimball, Chairman of the Meetings and Program Committee, explained that the sub-committees referred to were intended to supply material for certain of the sessions at the Spring and Annual Meetings; and that sometimes they were effective and sometimes not. Instead of maintaining these as standing committees with continuous tenure of office, it was proposed to appoint committees for a fixed term as required, in order to carry out definite assignments, after which the members would go out of office automatically. By this means no committee could remain for several years on the list in the Year Book without accomplishing results.

President Cooley, referring to committee activities in general, said he had sent a letter to all members of committees and to all chairmen of Local Sections, requesting information as to the work of the committees in the first instance, and as to who were available for committee appointments in the second instance. In July he would go over the replies received and investigate the work of the various committees.

Research and Standardization

Arts. 7, 8 and 9 were next taken up. These proposed that the Society secure and appropriate funds for the conduct of research; formulate problems for investigation, and secure men and facilities for their solution; and that the Society establish the policy of formulating and adopting engineering standards (which, however, should be limited to elements), such standards being considered as progressive and not as ultimate. The resolutions as presented were approved.

W. E. Symons, Chairman of the Finance Committee, issued the warning that "we can't by resolution or legislation make one dollar into two," and stated that the appropriation for the Research Committee for the present year had been $4000, of which a considerable amount as yet remained unexpended. In response to his inquiry as to the desires of the Aims and Organization Committee with respect to funds and appropriations, Mr. Alford said that the committee was dealing with principles only and that there was no time limit whatever on the resolution. There was no thought of changing this year's appropriation, but that as the Society grew and its income increased it was believed that it should be the duty of the Society to secure and appropriate larger funds for research work.

Secretary Rice said that he hoped the Society, with an annual budget of $300,000, would appropriate more than $4000 for research. It should so spend at least one-tenth of its income, which, in good Bible terms, is considered a tithe of its income, for the benefit of others. The American Society of Heating and Ventilating Engineers, with a membership of about 1100, had collected a fund of $80,000 for the advancement of their art and science and Dean Allen of the University of Minnesota was to be the director of their research work at Pittsburgh. If necessary to accomplish the purpose, there could be a readjustment of our funds, certain committees receiving smaller appropriations and the Research Committee more. Past-President Oberlin Smith testified to the pressing need for research as shown by the discrepancies in the information given in our handbooks. C. H. Bierbaum, Chairman of the Sub-Committee on Bearing Metals, also emphasized the importance of research and standardization and said that it was a happy conclusion to the resolutions that they recommended simply the standardization of elements and not the combination of elements and that the work be not considered final at any time. During the discussion Frank B. Gilbreth, who had recently studied conditions in England, urged as an important subject for study and investigation, the fatigue of working men and women.

Industrial Engineering

The next resolution, Art. 10, recommending that Industrial Engineering be made a major topic of discussion, was introduced by Walter B. Snow, and at once brought a call from Alex Dow for a definition of Industrial Engineering, and from Charles E. Lord for an explanation of the distinction between the expression "Industrial Engineering" and that used later in the report, "Industrial Relations." Several tried their hand at definitions, a definition of industrial engineering. Mr. Snow said it was "engineering which has to do with industry." Professor Kimball said it was a well-understood term, difficult to define. It related more to the construction and operation of factories as distinguished from the design of clearly defined engineering construction. Robert T. Kent offered as a definition, "The application and use of the materials and machines of engineering in the industries; this to include problems of management and labor." Mr. Gilbreth gave a definition attributed to Mr. Kent's father, the late William Kent, who used to say, "Engineering is the

science of overcoming the resistance of nature, but industrial engineering is the science of overcoming the resistance of human nature." Professor Kimball explained that, assuming industrial engineering to have to do with the construction and management of plants, there exists a field still further away from design that has to do with the human element—the field of industrial relations between employer and employee, in which engineers can play a very large part.

Without further discussion the resolution of Art. 10 was adopted.

Education and Special Training

Arts. 11 and 12, introduced by Sumner B. Ely, approved the work now being done by the Society in connection with Student Branches and technical schools of higher grade and recommended that this work be strengthened; and that a strong committee should be formed to extend this work among the industrial school below the grade of colleges. Louis C. Marburg, Chairman of the Committee on Aims and Organization, expressed the belief that the field offered great opportunities of such importance to engineers that it should have thorough consideration by the Society. The resolutions were adopted.

Professional Sections

In view of the fact that there had been several requests for professional sections, as provided for by the Constitution, such as an ordnance section, power-plant section, etc., the resolution in Art. 15, introduced by S. N. Castle, was proposed, recommending a Standing Committee on Professional Sections. This resolution was approved after a brief discussion calculated to bring out the purport of the resolution. L. C. Marburg explained that as it was proposed to broaden the scope of the Society—with the attending danger that it might become superficial in dealing with technical subjects, it was desirable to have professional groups to which specific topics could be referred for treatment. In response to an inquiry, Mr. Marburg said that such groups would naturally form in the sections of the country where the industries which they represented were centered, but nevertheless, as further explained by Secretary Rice, they would represent horizontal divisions of the country rather than vertical and would be nationwide in their membership.

Development of the Society's Publications

Next in order were three resolutions introduced by G. K. Parsons, relating to the Society's publications, as follows:

16. Resolved: that Mechanical Engineering (The Journal) be made a weekly publication at the earliest possible date, and that the Committee on Publications and Papers be encouraged to publish matter of broader scope, including papers and articles that have not been presented at any meeting of this Society, news items of engineering interest, and the information of general interest now presented in Bulletins.
17. Resolved: that the Committee on Publications and Papers be requested to study the possibility of a substitute for the present expensive method of publishing the Transactions, presenting any plan developed to the members of the Society for letter ballot.
18. Resolved: that the Society publish, as soon as practicable a Handbook of Mechanical Engineering Data.

In introducing these resolutions, Mr. Parsons said they had been carefully worded to apply only "at the earliest possible date" and "as soon as practicable;" and as they were intended for the Council, and through them would be considered by the Publication and Finance Committees, their practicability would be determined by these bodies.

Discussion of Art. 16, Relating to the Development of "Mechanical Engineering" (the Journal). W. E. Symons, Chairman of the Finance Committee, opposed the more frequent publication of Mechanical Engineering on the grounds (1) that it would be regarded by other publications as a competitor and that their good-will which we now possessed would then be changed to opposition such as naturally results from commercial competition; and (2) that we would be in a position to suffer a heavy financial loss. He contended that it would be easy to lose a quarter of a million dollars in attempting weekly publication.

R. T. Kent testified to reading Mechanical Engineering thoroughly each month; but if issued in the weekly form he felt he would not have time to read it. He disapproved of soliciting contributions for publication except as presented at meetings, as he thought this would bring the Journal in direct competition with the technical press.

L. P. Alford called to the attention of the meeting that the Electrical Engineers had recently passed a resolution asking for the improvement and expansion of their journal and for an increase in its size to the standard 9 by 12 inches; and that a similar resolution was before the Mining Engineers, with prospect of adoption. He took exception to the suggestion that a weekly publication would earn the ill-will of other publishers. He spoke as an editor-publisher and would welcome the upbuilding of the Journal, since whatever was done to advance clean journalism would help his publication. Mr. Alford suggested that Major Fred J. Miller, who had had something to do with the establishment of the Society's Journal and had lately been investigating its possibilities for the future, should give his impressions.

Major Miller, in response, reminded the meeting that the resolutions of the Aims and Organization Committee were made by delegates representing the membership from all parts of the country; that they thought the Journal a good thing and wanted more of it. The qualification "at the earliest possible date," however, indicated that they did not expect the Society to bankrupt itself by making a weekly before it could be done advantageously. He said: "I believe the Journal occupies a field which is distinctive; that is a kind of a journal which no private publisher would probably want to undertake; and that it occupies a field which is not otherwise occupied. A journal either dies of dry rot or it goes ahead and progresses with the progressive ideas of the age and that is what the Mechanical Engineers' journal must do." He then outlined certain definite things which should be done in the development of the publication, such as the extension of the Engineering Survey, by which an engineer can keep in touch with the high lights of his profession without having to read 25 or 30 special journals; and by the strengthening and enlargement of the editorial staff, to permit the gradual enlargement of the Journal and to make it possible for one of the editors to travel and come into personal contact with the membership in different parts of the country.

Following these developments, if the Journal should have grown normally to the point where still more space was needed and the advertising income were sufficient, he could not see how it could become obnoxious to other publishers if it were made a semimonthly or a weekly, so long as its character were maintained, with the same kind of reading matter and under the same editorial direction. He was in favor of conservatism in the matter, as we were under obligation to be when handling the interests and the money of a professional society such as this. The whole thing could be summed up in so conducting the Journal that it would render the best possible service to the membership.

Mr. Symons, in reply to Major Miller's assertion that there were stages in the life of a journal where it might cease to progress and "die of dry rot," called attention to the marked growth of Mechanical Engineering during the past seven years, in circulation, advertising increase, money expended for production for the benefit of the membership, etc. Whereas the publication is very healthy now, he felt that if it were made a weekly it might become very unhealthy from a financial standpoint.

Alex Dow said that Mechanical Engineering was one of the few papers which he, a busy man, had time to go through "from cover to cover," and that it was one of the few papers whose make-up and advertising he admired. He wouldn't go through it if it came once a week, and so with many others. And herein, he thought, was a measure of its present advertising value. It is read by the very ones who do not read the weeklies. He therefore

took exception to the point in the resolutions relating to the weekly—it was an error in judgment—and he moved that the words "That Mechanical Engineering be made a weekly publication at the earliest possible date" be stricken out. The motion was seconded by W. O. Witherspoon, who said that he was a busy member of several societies and that what was needed was not so much more matter, but a stricter censorship of what was put in their journals.

During the debate on the question of the development of Mechanical Engineering the discussion drifted at times upon questions of practicability, in spite of Mr. Parsons' statement in introducing the resolutions that this was a question for the Council and the committees interested to determine. There was also considerable discussion as to expense involved and the utilization of the Society's reserve, details of which W. E. Symons, Chairman of the Finance Committee, contended should be made available so that "anybody who votes in the affirmative or negative on a question of such great and vital importance to the Society should know what he is voting on, expressed in dollars and cents." In the course of this discussion President Cooley, as chairman, asked to have the discussion confined to the general problems involved, as intended by the Committee, saying, "You needn't be afraid the Council will get you into trouble. The Publication Committee will have to come before us with figures, and if the Council is not sure of itself it will come to you again."

In justice to the Publication and Papers Committee, also, it should be told that the sentiment of the meeting with respect to the mission of Mechanical Engineering, the field which it is now filling, and its possibilities for development was most favorable. If the members of the Committee who were present were not embarrassed by the many good things which were said, the remarks at least must have been gratifying, as an expression of appreciation of their work.

The motion as amended by Mr. Dow was finally adopted.

Discussion of Article 17, Relating to a Substitute for Transactions. W. C. Brinton, in referring to Transactions, discussed also the procedure in handling papers in the Journal. In general, he proposed curtailment in the publication of papers, but that they be issued more completely in loose-leaf form, such copies being announced in the Journal and supplied to the membership as desired. Major Miller called attention to a similar proposal made several years ago, to do away with the bound volumes of Transactions and to substitute therefor papers printed in sections. Members would receive the sections of interest to them and not be burdened with the others. The plan had failed—members liked the looks of the bound volumes on their shelves—but it might be proposed again.

Secretary Rice said the Society was under obligations to supply Transactions, unless the membership should vote otherwise. In 1893 the membership dues were raised from $10 to $15 a year and it was agreed that if the members would stand for this they should receive Transactions in perpetuity. Mr. Rice, however, said the United States is the only country in the world where professional societies have to print the papers read at meetings in pamphlet form; then publish in the proceedings and later in a bound volume. The Society should consider whether it would not reduce this waste and put the money to a more useful purpose. R. T. Kent expressed a desire for the bound volumes, but believed the expense could be reduced, and advised the appointment of a committee to look into the matter. Jesse M. Smith contended that this was a function of the Publication Committee; and further, in respect to the wording of the resolution calling for a letter ballot on the subject, said that the matter could be more effectively handled by having the proper committee report to the Council, they in turn bringing up the report for discussion at a convention. Mr. Kent finally proposed an amendment to Art. 17, substituting for the words "letter ballot" the words "to report at the Annual Meeting." Mr. Smith seconded the motion, which, as modified, was later adopted.

Discussion of Art. 18 on the Publication of a Handbook of Engineering Data. In the discussion of this project it developed that the Committee had no definite plan to offer for a handbook, but that it believed it should be considered in its broad aspects with the possibility that a satisfactory plan would be developed. It was stated by Mr. Parsons, who introduced the resolution, that there was no intention of competing with any of the excellent handbooks now on the market. Following this statement, R. T. Kent said he felt free to discuss the resolution. If the Society were to publish a handbook which would not compete with any of the other handbooks, where is the field for it? What kind of data would it propose to put in? Had the Society considered the expense, which would run into thousands of dollars?

Major Max Toltz favored a handbook which should contain the data gathered by the Society. L. P. Alford said similar data were already published in Condensed Catalogues and thought that these data, with other material added, should go in a handbook. In reply to an inquiry as to the usefulness of Condensed Catalogues, Major Toltz said that in the West, where data readily available in New York are not accessible, the book was in constant use and that "we absolutely need it." Mr. Rice reported that an engineer in Salt Lake City had told him it was "the finest thing the Society gets out."

The resolution as offered was adopted, this and the two preceding as amended, being passed at the conclusion of the discussion.

Absence from Committee Work

Discussing Art. 19, dealing with absence from committee work, Major Toltz thought that the resolution if adopted and literally carried out would operate as a practical bar to western men serving on committees. Past-President Jesse M. Smith called attention to C-51 of the Constitution, which provides an effective means for removing inactive members from committees. Major Fred J. Miller stated that in his experience with the Society's work it had been very difficult to get action on any specific case of neglect of committee work, and the provision of the resolution therefore seemed to him eminently desirable. Carried.

The resolution in Arts. 20 and 21, on the Society's employment activities, were adopted without discussion.

Code of Ethics

Past-President Charles T. Main opposed the resolution in Art. 22 relating to abolishing the Society's Code of Ethics on the ground that many of the younger members found it of advantage to have a program outlined as a guide for their professional conduct. If it was imperfect it should be revised and amended. Past-President Oberlin Smith spoke in the same strain. Robert Sibley felt that the resolution should be defeated and spoke of the voluntary raising of $20,000 by engineers on the Pacific Coast to put forward a code and carry on education work among engineers in order that it might be put in practice.

Charles E. Lord called attention to the action taken at a recent meeting of the Committee on Development of the American Society of Civil Engineers in Minneapolis, which he attended as a representative of the Committee on Aims and Organization. In line with that action he proposed the following substitute resolution:

> Resolved: That it is the sense of this meeting that a short Code of Ethics of broad scope, general character and position rather than negative injunction, be proposed and that the same be enforced vigorously.

Jesse M. Smith approved of Mr. Lord's resolution with the exception of the clause regarding enforcement. There had been exceedingly few infringements on the codes of ethics of the national societies, and it seemed to him that the penalty for infringement should be in the sense of non-recognition by other members rather than expulsion or other forcible action.

Forrest E. Cardullo disagreed with the previous speakers and said that the Society did not need a code of ethics. All that was necessary was that members should be decent, honest men. Codes of ethics were heritages from an earlier day when the condition of the profession and the character of the men practicing them required such formulations.

Wm. T. Magruder then presented the following resolution

which embodied suggestions made by Messrs. Jesse M. Smith, Max Toltz and C. E. Lord:

> Resolved: That a committee of five on Code of Ethics be nominated by the President and confirmed by the Council, who shall report back to the Society at the Annual Meeting.

L. P. Alford, on behalf of the Committee on Aims and Organization, withdrew the original motion and those proposed by Messrs. Lord and Magruder were then unanimously adopted.

Relations of the Mechanical Engineer to the Community

Mr. Lord, chairman of the sub-committee that prepared the articles dealing with the relation of the mechanical engineer to the community (Arts. 23-50), at the suggestion of Mr. Alford read the first eleven articles. The resolutions offered, he said, were practically self-explanatory. The idea presented was one of federalization rather than amalgamation. It was to be clearly understood that there was no desire to change the status of existing engineering societies so far as any technical questions were concerned, but to develop some sort of coöperative agency for dealing more effectively and interestingly with economic, social and political matters. He then told briefly of similar activities on the part of the development committees of the Civil, Mining and Electrical Engineers and asked that Arts. 27-33 be approved.

Frederick H. Low offered the following as a substitute for Arts. 23-33:

> The Society commends the interest taken by its members as individual citizens in municipal, state and national affairs and recognizes that the local engineering societies are the natural and most effective exponents of engineering ideals as applied to public business.
>
> Therefore, the Society endorses the policy heretofore pursued by the Committee on Local Sections in conjoining the activities of our Sections with those of the local and state societies:
>
> Further, the Society looks with favor upon and will aid in the formation of a national organization of local societies whereby the voices of engineers as citizens of the United States may have their full value in the discussion of national and international questions.

Alex Dow stated that he believed in one keeping his different expressions of personality through his various affiliations separate. As a member of the Detroit Engineering Society he was not an engineer first but a citizen of Detroit. In the national societies he discussed engineering matters, but in the local society he discussed Detroit from the viewpoint of the engineers of Detroit. He entirely approved of the suggestion made that each member of the Society should be a member of a local society and express in that local body and in the affairs of the community the engineering ideals of truth which we must grow up with. The Society, however, should not undertake to embrace everything that was good, but should say that within its doors men are mechanical engineers first, leaving other matters to be taken up as personal duties in the churches, primaries, caucuses and other organizations of social and political life.

E. S. Carmen said that he could not see that Mr. Low's resolutions differed from the spirit or sentiments expressed in the remarks of Mr. Dow. Resolutions placed it entirely in the hands of the local and coöperating societies to unify the engineering professional work to and for the same high principles of citizenship.

Jesse M. Smith moved that the references to Cleveland, Philadelphia, Minnesota and Ohio in Art. 31 be stricken out, as he thought it was drawing an invidious comparison between the work done in those communities and that done in others. Carried.

Charles E. Gorton thought that the matter under consideration should be referred back to the Committee, to the end that similar committees of the other national engineering societies be consulted and something more tangible be evolved for presentation to the members for their approval.

L. C. Marburg, on behalf of the Committee, explained that the resolutions upon which a vote was asked would not be binding on the Society—they would simply be an expression of opinion as to the general plan. A joint committee had recently been created, consisting of representatives of the four Founder Societies, and at a meeting which it was proposed to hold in July in New York these matters would come up.

W. E. Snyder said it was becoming clearly apparent that the national societies wanted to do their utmost to meet the local societies in some sort of federation and that the resolutions before the meeting indicated a broad and liberal attitude and encouraged local members to attempt and continue the work. To him the original resolutions and Mr. Low's substitute were very similar. It made very little difference what phraseology was used—the spirit of the matter was the thing.

Jesse M. Smith said that he agreed with all that was stated in Arts. 31 and 32, with the exception of the word "independent" in Art. 32. This he thought to be a dangerous inclusion. He took a pardonable pride in recalling that the Local Sections of the Society were created in 1910 when he was its president. He had always stood for their development, but was fearful that it had been pushed too rapidly. Coöperation among the national societies was a most admirable thing and it pointed toward bringing all the societies together. He had outlined his views in this respect at the 1918 Annual Meeting, and in his address when installed as president in 1909 would be found the nucleus of what they were trying to bring about today. He was in hearty accord with Mr. Low's substitute resolutions, because they presented the substance of the Committee's views and yet avoided certain specific points which seemed to him dangerous.

W. E. Symons felt that the purpose of the resolutions as offered by the Committee was splendid. He was not, however, in accord with the method proposed for securing the objects sought, but was fully so with respect to Mr. Low's amendment. He could assure one of the previous speakers that any action taken on the resolutions before them would not be final, for a business meeting was not the Society's court of ultimate resort. The fundamental principles embodied in the Committee's resolutions were rather general in character and if later enacted into law and put into effect serious complications might arise. The cautions brought to their attention by Messrs. Smith and Dow and embodied in the amendment were timely, he thought, and should be heeded.

D. Robert Yarnall, while not sharing Mr. Smith's apprehension that the Sections were progressing too rapidly, felt nevertheless that in view of the fact that the resolutions offered by Mr. Low embodied the spirit of the Committee's presentment, the Committee might graciously accept them and thus avoid the dangers pointed out by Mr. Dow and Mr. Smith. He would therefore support Mr. Low's resolution.

Fred R. Low, who had earlier been called to the chair, took the floor and said that the idea of engineers coöperating was nothing new. The very plan referred to in the committee's resolutions had been in successful operation for years. One of the speakers who preceded him had said that there was a feeling in the Middle West that the national societies wanted to swallow up the local and state societies and that they were operated as a few men in the East wanted them to be operated. He did not believe that engineers in general had that feeling but that they had full confidence in the national headquarters of the Society. The Committee's proposal expressed from headquarters the sentiment that the Society wanted to encourage the local societies to incorporate all engineers within their local groups and devise some plan whereby a definite connection might be established between the locals, the large general local, and the national society, both technically and civically. There was nothing to fear, for at most, affirmative action on the committee's resolutions would be nothing more than a recommendation.

S. F. Jeter agreed with Mr. Smith that there was danger to be apprehended from the inclusion of the word "independent" in the resolution of Art. 32. An additional source of danger was the phrase "fully empowered to act." He could not see how a joint committee of all the societies in which mechanical engineers would have a one-to-three representation would be just and proper in the determination of questions strictly mechanical.

S. N. Castle said that there were at least 100,000 professional engineers in the country, 30 per cent of whom, barring duplications, are to be found in the national societies. The work of the

engineer, as he saw it, falls in two distant branches, his professional work and his work as a citizen, and to coördinate these two fundamental duties a working tool is needed. The spirit of the times was specifically for a formation from the ground up, comprising the purely local societies. From these a grouping into either state, geographical, social, economic or industrial divisions could be made. It seemed to him essential that with the present formation the highly desirable thing to do was to secure coordination between the local societies which handle primarily the community work, and the national societies which handle very largely professional work.

L. P. Alford, referring to Mr. Jeter's objection to the inclusion of the words "empowered to act" in Art. 32, said that the meeting the day before had definitely declared for an attitude of activity in indorsing the resolution in Art. 2 dealing with the adoption of standards.

In regard to coöperation, which, as he understood it, was the real meat of Mr. Low's resolution, it was not only the spirit of the times but, he believed, that of the majority of the Society's membership. Unwillingness to coöperate in the past had led in a number of instances to the withdrawal of members to form societies devoted to special branches of mechanical engineering, and many of the men thus lost were possessed of power and leadership. As he saw it, the issue was clean-cut. It was either to encourage the local organizations and reach out in the spirit of coöperation to other societies, or to stand pat and undoubtedly lose the advantages of other increases in membership which might have been had. He fully believed that the movement for coöperation was so strong that even rejection of the Committee's resolution could not kill it. The same movement was taking place in the other national societies and they were ready to go forward with the A. S. M. E. Was the latter to be the only society which would refuse to coöperate? Would it be the only one on the outside?

The Chairman then put to vote the motion to substitute the resolution offered by Mr. Low for Arts. 30-33 as submitted by the Committee, which was lost. The question of adopting the Committee's resolution was then taken up, but before a vote was taken, Jesse M. Smith moved to amend Art. 32 by striking from the last sentence the words "independent" and "fully empowered to act and." This motion being seconded, the amended resolution was adopted by vote.

Election of Officers

The resolution in Art. 50 was approved without discussion.

Art. 54 recommended that the Regular Nominating Committee, which as prescribed in the Constitution, is to be elected annually by the voting membership of the Society, should be composed of a member from each Local Section, each voting member of the Society being assigned to some Local Section by the Committee on Local Sections exclusively for the purpose of electing a Nominating Committee member. Robert Sibley criticized this resolution on the ground that a committee so composed would consist of too many members to be able to dispatch business adequately and secure harmonious results, and suggested reducing the membership of the Nominating Committee by dividing the country into a grouping of sections and that these groups nominate a committee of five. Such an arrangement, Jesse M. Smith argued, would create a condition whereby the Sections would be unequally represented because it would give the same representation to everyone of the Sections regardless of the number of members of the Society who might constitute it. To this objection Robert Sibley, and subsequently Louis C. Marburg, John J. Simmonds, Lawrence W. Wallace, H. John O. Hinchey and several other members, answered by observing that the Society being a national organization, it appeared to them more convenient to divide it into geographical groups for the purpose of representation in the Nominating Committee than to create the impression that its activities were being conducted principally for the benefit of those members who are residents in the localities where the greatest membership is at present found.

Secretary Rice observed that the provisions for selecting and organizing the nominating committees have not been written as yet in the By-Laws, and in this connection Jesse M. Smith said that the various views brought out during the discussion would enlighten the Committee on Constitution and By-Laws as to the sense of the membership in the manner of carrying out the constitutional amendments just adopted by letter ballot. No modification to the text of the resolution was proposed. President Cooley said in conclusion that although the subject had not been exhausted the discussion had been carried far enough so that the Committee on Aims and Organization could revise its recommendation to the Council.

The recommendation in Art. 55 requesting the Committee on Constitution and By-Laws to prepare such changes in the procedure for the annual election of officers as would permit the declaration of their election by November 1, was favorably commented upon by President Cooley, who expressed the opinion that such provision, if carried out, would permit a president to be coached in his duties before he actually assumed office, in which event the work could go on much more continuously and much more effectively. Jesse M. Smith spoke on the advisability of notifying the President of his nomination as early as possible, even at the Spring Meeting, and moved to substitute for "November 1" the words "a considerable time, to be determined by the Council." The motion was carried.

No changes were made in Art. 56, which was adopted in its original form as drafted by the Committee.

Following the acceptance of Art. 56 L. C. Marburg observed that as several of the resolutions which had been discussed and approved would call for constitutional amendments he would like to submit the following proposals. C-49 now reading:

C-49 Professional Committees:—The Council has the power to appoint, upon the recommendation of the Society at a general meeting, or upon its own initiative, such professional committees as it may deem desirable to investigate, consider and report upon subjects of engineering interests, but shall not be approved or adopted as the action of the Society. Any proposed expenses of such committees must be authorized by the Council before they are incurred.

To be amended to read as follows:

C-49 Professional Committees: The Council shall have power to appoint, upon recommendation of the Society at a general meeting or upon its own initiative, such professional committees as it may deem desirable to investigate, consider and report upon subjects of engineering interest. And proposed expenditures of this committee must be authorized by the Council before they are incurred. Reports of such committees may be accepted by the Society and printed in the Transactions.

C-50 The Society may approve or adopt any standard formula or engineering practice, but shall not approve any engineering or commercial enterprises. It shall not consent to the use of its name or initials in any commercial work or business, except to indicate conformity with its standards or recommend practices.

This proposed C-50 would supersede the present C-56.

C-45 *to be amended by adding* "Committee on Professional Sections" *and changing the sentence* "The Chairman of each Standing Committee of Administration shall have a seat in the Council......" so it would read: "The Chairman of all Standing Committees shall have a seat in the Council......"

C-50, reading at the present time as follows: "Each committee shall perform the duties required of it in the By-Laws or assigned to it by the Council; the Secretary of the Society shall be the Secretary of each of the standing committees," *to be amended by adding after the first sentence the following:* "Membership on the Council or any committee of the Society shall terminate automatically on account of absence of any member, either willful or due to force of circumstances, as provided in the By-Laws."

The last amendment elicited much discussion and some members considered its operation would deprive the Society of important and valuable membership on committees on the part of those whose names and prestige would make it desirable that they should serve even though their geographical position would not permit them to attend every meeting.

CRUDE-OIL MOTORS vs. STEAM ENGINES IN MARINE PRACTICE

BY J. W. MORTON[1], PHILADELPHIA, PA.

This paper is devoted to a discussion of the various factors to be considered in choosing the form of motive power for war vessels and cargo ships; also to a presentation of the advantages and disadvantages, as compared to steam engines, of crude-oil motors of the following types: constant-pressure, constant-volume, four-stroke cycle and two-stroke cycle. In the complete paper there will be found a description of some of the details of motor construction, dealing with lubricating systems, piston cooling and scavenging pumps.

THE number of articles which have appeared of late describing the performances of the so-called motorships would seem to indicate that for marine purposes the crude-oil motor is rapidly replacing the steam engine. The chief reason for this is not to be found, as might be expected, in the lower operating cost of the crude-oil motor but is rather due to other factors which when considered lead to the conclusions that it is probably the most economical prime mover of today.

Perhaps the correctness of this statement can best be shown by comparing a steamship with a motorship. In the case of a war vessel, for instance, there are eight factors which ought to be considered in choosing the form of motive power, namely, weight, space occupied, radius of operation, preparedness, crew necessary, fuel, auxiliary equipment, and cost.

The weight of the power plant is of great importance, for a saving therein can be utilized to increase the armor of the ship. If for example, a warship of 3500 tons displacement or equipped with crude-oil motors there would result a saving as indicated by Table 1 which is based on a single steam engine developing 4400 hp. and 3 units of 1600 hp. each of a standard make of crude oil motor.

TABLE 1 COMPARATIVE WEIGHTS OF POWER PLANTS IN STEAMSHIP AND MOTORSHIP

	Steamship		Motorship		Saving in Motorship	
					W'ight Tons	Per Cent
Engines, tons	335		264		71	
Per cent of displacement		9.6		7.5		2.1
Fuel, tons	246		86		160	
Per cent of displacement		7.0		2.5		4.5
Crew, Provision, Water, tons	91		82		9	
Per cent of displacement		2.6		2.3		.03
Totals	672		432		240	6.9

In the case cited about the same space would be required for both motor plant and steam plant, but the total horsepower could just as well be developed by two units of slightly larger size, and if this were done approximately one-third the space would be saved. Moreover if oil motors were used the space occupied by the coal bunkers could be partially released, as crude oil can be stored in tanks under the engine floor and below the protective line.

It is obvious that a warship must possess a great cruising radius and if weight for weight of engines be considered then the ratio R of the cruising radii of a steamship and a motorship be expressed by the formula:

$$R = \frac{V_c \times H_o \times W_c}{V_o \times H_c \times W_o}$$

where V_c = cu. ft. occupied per ton of coal = 45
V_o = cu. ft. occupied per ton of oil = 35
H_c = B.t.u. per lb. of coal = 12,500
H_o = B.t.u. per lb. of oil = 18,000
W_c = Lb. coal consumed per e.hp-hr.
W_o = Lb. fuel oil consumed per e.hp-hr.

In the case of the warship under consideration if W_c be taken as 2 and W_o as 0.5 then the ratio will be

$$R = \frac{45 \times 18000 \times 2}{34 \times 12500 \times 0.5} = 7.4$$

The cruising radius will of course vary according to the type of engine and ship, but nevertheless the average ratio as expressed above may be taken at least as 1 to 5 in favor of the crude-oil motor.

A motorship in sharp contrast to the steamship is always ready for action, as no time is lost in getting up steam. Moreover, fuel is consumed only when the motors are running, and the motorship is capable of maintaining full speed as long as there is a supply of fuel.

As there is no need for stokers on a motorship, the crew can be decreased about 10 per cent and this of course permits of a corresponding saving in provision, water storage and quarters.

In the case of a steam-driven warship the smoke from the stack frequently betrays the location of the ship, for it is well known that a vessel can be easily located by its smoke long before the masts or hulls are in sight. Another drawback to the steam-driven warship lies in the fact that the smoke covers the ship with a film of soot which, getting into vital parts of auxiliary machinery, necessitates frequent cleaning and unnecessary wear and tear. On the other hand, when oil is used there is no smoke, the handling of the oil is both cleaner and easier, and the life of machinery and equipment is greatly increased.

When a change is made from steam to oil the auxiliary machinery is usually electrically driven, as this has been found to be the most satisfactory. The dynamos are usually driven by separate oil engines. Hot water for heating and sanitary purposes is obtained from a small oil-fired boiler and while the first costs of such installations are high, they are in time offset by the lower operating costs.

Prior to the war the first cost of a crude-oil motor plant was approximately twice that of a steam plant. This was partly offset, however, by the savings in operating expenses, under which item comes cost of fuel, labor and supplies. The cost of fuel naturally depends upon the prevailing market for coal and oil. In regard to maintenance there is practically no information available as the crude-oil motor is still in its infancy so far as this country is concerned.

CARGO SHIPS

Many of the preceding statements concerning the installation of crude-oil motors on battleships can also be properly applied to cargo ships. During the last four years a number of such vessels have been equipped with crude-oil motors of both the two-stroke and four-stroke cycle type, and while engineers are not agreed as to the best type, the four-stroke cycle seems to be preferred.

One of the most successful installations of this kind is that found on the motorship *Suecia*. This ship has a length of 362 ft., a beam of 51 ft. 3 in., a depth of 25 ft. 6 in., and a capacity of 6550 deadweight tons, has twin screws driven by two 1000-hp. Diesel engines of the 8-cylinder 4-cycle type, and also two auxiliary engines of 200 hp. each. The vessel was built for service between Sweden and La Plata and its first run was a test made on December 4, 1913. The curves in Fig. 1 give some idea of the characteristics of the motors. The dotted curves are given for the sake of a comparison with the steamship *Princessan Ingeborg* built two years before the *Suecia* and for the same company. The

[1] Asst. Engineeer, Diesel Engine Unit, U. S. Shipping Board, Philadelphia, Pa.

Presented at the Spring Meeting, Detroit, June 16 to 19, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form. Copies of the complete paper may be obtained at a nominal cost. All papers are subject to revision.

Princessan Ingeborg has a length of 300 ft., a beam of 48 ft. 9 in., a depth of 22 ft. 4 in., and a capacity of 5895 deadweight tons. The coefficient for the *Suecia* is 0.78 and for the *Princessan Ingeborg* 0.794 and thus both vessels are about equal in size and excellence. A comparison will show that the same amount of power is necessary to obtain equal speeds when the displacement are equal. This would seem to indicate that there is no difference between transmitting power through two small comparatively fast-running screws as is done on the motorship and transmitting power through a single slow-running screw as in the case of the steamship. The propeller on the steamship has a diameter of 17 ft. while those of the motorship are only 10 ft. The ratio of indicated to effective horsepower is, therefore, the same for both ships and the total efficiency of engines and propellers is also about the same.

In order to correspond to the motorship in horsepower the

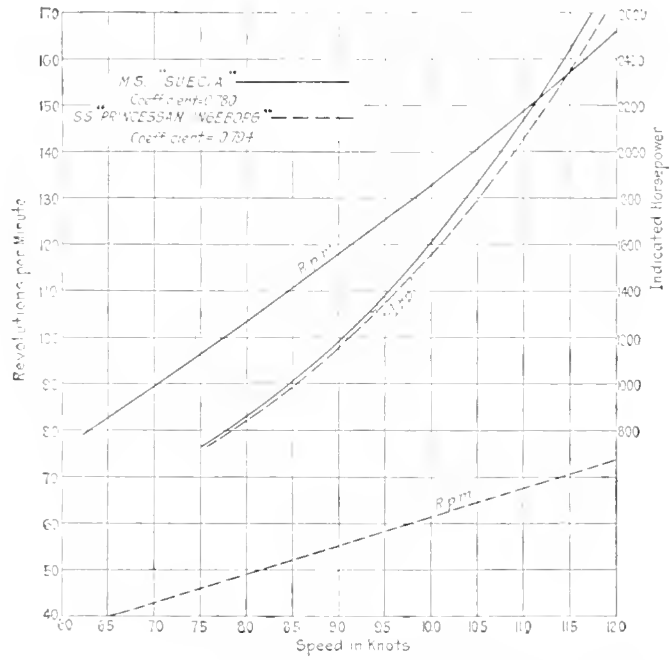

Fig. 1 Motor Performance Curves of Steamship and Motorship

steamship would be obliged to carry an extra boiler. This would increase its weight 570 tons whereas the weight of the machinery on the motorship is only 470 tons. The length of the engine room of the motorship is 41 ft. while the length of engine room and necessary boilers in the steamship is 66 ft. and this despite the fact that the steamship has less horsepower.

The fuel consumption during the trial trip of the *Suecia* was 0.2948 lb. per i.hp. or 0.3685 lb. taking the mechanical efficiency at 80 per cent, a very satisfactory value. Table 2 affords a comparison of this vessel with other motorships.

Motor Sizes and Types

The horsepower of a crude-oil motor, whether of the constant-volume or constant-pressure type, is somewhat limited by practical considerations of construction. At the present time the maximum size is 2500 hp. per shaft and from six to eight cylinders for the two- and four-stroke cycle constant-pressure type, although some experimental motors have been built as large as 6000 hp. This is in sharp contrast, however, to the power developed by steam, which runs as high as 15,000 hp. for the steam engine and 35,000 hp. for the steam turbine.

Crude-oil motors of small horsepower are usually of the high-pressure type, intermediate, so-called semi-Diesel or hot-bulb type and two-cycle constant-volume type. Prominent among such semi-Diesel motors are the Bolinder, Scandia, Abance, Alliance, Tuxhan, Gidion and Holm.

It has been proven both by experiment and practice that the constant-volume high-power single-cylinder type of motor is unsatisfactory, and chiefly because of the fact that the enormous heat generated at the pistons during the explosion must travel a great distance before it is transferred to the water jacket; and as a result the central part of the piston is heated to such an extent that preignition frequently occurs. Furthermore, the sudden rise in pressure sets up detrimental vibrating stresses in the material, and it is also exceedingly difficult to obtain a proper mixture of air and oil, rapid ignition and complete combustion and exhaust.

On the other hand, the constant-pressure oil motor of high power must have numerous cylinders all of the same size, and the high pressure, which lasts approximately 10 per cent of the stroke, necessitates a careful design of the crank mechanism. This applies especially to the crankshaft which is both difficult and costly to produce. Moreover, in motors with only a few cylinders the flywheel must be heavy, large and expensive if there is a great variation in speed. Difficulties have also been encountered in keeping the piston leakproof: if it fits too tightly the result is a large frictional loss, and if the clearance is too great there will be a loss of pressure. The greater the piston area the more effective must be the cooling system as the surface exposed per pound of working medium decreases as the cylinder dimensions increase. This accounts for the lower thermal efficiency and the horsepower available per unit of piston surface with large cylinder size.

Low-Power Motors

Advantages. The efficiency of an oil motor is greater than that of a steam engine, especially in small units, and furthermore it decreases less with increasing load. The fuel consumption of an oil motor is independent of the attendants' skill, as it shows the same value in daily work as on a test stand. With a steam engine, however, the fuel consumption is dependent upon the attendants, and especially the stokers, who must be experienced.

In steam plants the boilers and pipes must be able to withstand high pressures and temperatures, but with oil motors a high pressure exists only in the cylinder and a few small pipes. Moreover, the oil motor is simpler in construction and the weight and space occupied considerably less. It is of interest to note in this connection that the steam turbines in torpedo boats weigh about 45 lb. per b.hp. and aeroplane motors but little over 1 lb. per b.hp.

The small oil motor has other advantages over the steam engine and these can be briefly enumerated as follows: Starting takes only a few seconds; fuel is consumed only during operation; combustion in the motor cylinders can take place for a long period of time; the motors require little attention and the oil tanks can be refilled more easily than coal bunkers and without the dirt which accompanies the latter procedure.

Disadvantages. It must not be thought that oil motors have no disadvantages, for there are many, and chief among them may be mentioned the following: Fuel oil is more expensive than coal and is not available in all ports; furthermore, lubricating oil consumption is greater than in the case of steam engines as one must deal with higher temperatures and, as a rule, higher pressures. The operation of a crude-oil motor is also more irregular than that of a steam engine as oil motors cannot be run as slowly as is desirable when reversing from ahead to astern. The causes of interruptions (especially with electrical ignition) are often difficult to locate; the motor frequently works noisily with smoking and malodorous exhaust; the danger due to fire and explosion is greater, and the life of the machine is considerably less.

High-Power Motors

Advantages. The statements made in regard to the low-power crude-oil motor are also true to a certain extent in the case of the high-powered, but in addition the following items should be noted: With larger output the economy of a power plant becomes of greater importance. The low efficiency of most steam plants is due to the fact that the heat generated must travel through heavy boiler plates, and that there is a great loss of heat through exhaust, and condensation of steam. Furthermore, the steam plant operates with a small temperature difference which ought not to be increased because it is very desirable to work with

high temperature limits. With saturated steam the pressure soon increases beyond a practical value, and with superheated steam the walls of the superheater soon reach their limit as they should never be allowed to become red-hot. On the other hand, in the oil motor the heat formation and utilization take place in the working cylinders, and the high temperature limit is therefore the same as the temperature of combustion. The value of the lower temperature limit is greater than in a case of a steam plant, but the heat difference of the process is higher.

Another advantage of the oil motor is due to the ease with which the air supply necessary for complete combustion is regulated, and since the point of ignition is practically constant, there results complete combustion. On account of the great heat which exists in a boiler room it is very difficult for the stokers to maintain normal pressure; the coal consumption is accordingly increased but the speed of the vessel decreases. On the other hand, in the case of the motorship the reverse holds true. If the fuel oil becomes warmer it is more easily vaporized, with the result that fuel consumption decreases while the speed of the vessel increases.

Since fuel oil can be stored in tanks a considerable saving can be made in space, more oil can be carried and a greater cruising radius thus afforded. The weight of a slow-running four-cycle stroke oil motor for a cargo ship is about the same as that of a steam plant, but far less space is required. The horsepower and speed are about the same for a twin-screw motorship as for a single-screw steamship, but as the former's screw diameters are smaller its efficiency is greater and the vessel can thus be more easily maneuvered. The cylinders of a motorship are all similar, and since they work independent of each other, one or more of them can be put out of service and the motor still continue to operate.

Steam boilers and their fittings require as a rule a considerable outlay for repairs and maintenance; also the sides and bottom plates of the hull which are nearest to the coal bunkers are likely to corrode because of the sulphur content of the coal and in addition sea water in the ballast tanks may also cause corrosion of the plates. On the other hand, a motorship has no boilers and the fuel is stored in bottom tanks and this very fact is a great advantage since such tanks are protected by the oil.

Disadvantages. In a case of a single-cylinder oil motor the torque acting on a single shaft is limited but, everything else being equal, such as shape and line of hulls, propellers, r.p.m. and b.hp., the indicated hp. of the motorship will be greater than that of the steamship.

Since the reciprocating parts in a crude-oil motor weigh more than those of a steam engine the balancing of the masses is more difficult and the shifting forces greater. At light loads the pistons in a large motor are not tight enough to maintain high compression and since the combustion space is not sufficiently warm for positive self-ignition, large motors can only be run when under light loads at approximately one-third to one-fourth normal speed. Furthermore, the heat transmitted to the cooling water per unit area of the cylinder is about $2\frac{1}{2}$ times as great in a combustion chamber as in the cylinder walls, accordingly the heat drop in the cylinder wall is very considerable and tends to introduce stresses in the material, and if the limits of the elasticity are exceeded these stresses will be transmitted to distant parts. The material is also subjected to high stresses as a result of the rapidly repeated power impulses, the high temperatures, and great pressure in the cylinder.

TABLE 2 DATA ON VARIOUS CARGO MOTORSHIPS

(Number of main motors on each ship=2)

Name of Ship	Year placed in service	Owner	Hull					Machinery							
			Length ft.-in.	Beam, ft.-in.	Depth, ft.-in.	Capacity, deadweight tons	Speed in knots	Total i.hp.	No of cylinders in each motor	Bore, mm.	Stroke, mm.	R. p. m.	Ratio of Stroke to bore	Piston speed, meters per min.	M. e. p., kg. per sq. cm.

*Cargo and passenger vessel.

CONSTANT-PRESSURE MOTORS

Low-Pressure Types. The low-pressure oil motor is perhaps the simplest prime mover of its kind and is especially adapted for use in small boats where the operators are usually unskilled. The chief advantages of this type of motor are its low first cost and small operating expenses. Furthermore, the low temperature in the cylinder and the low explosion pressure together with its simplicity of operation make it a motor of great durability. This type, however, has some disadvantages and chief among them are its small power output, large cylinder dimensions, excessive weight and long time required for starting.

Hot-Bulb Type. The so-called hot-bulb motor operates at a medium pressure, with or without water injection. While the tendency today is to avoid water injection, if the hot-bulb motor be nevertheless operated with water injection its fuel consumption will be comparatively low; the temperature of inlet air low; overheating of cylinder and piston will seldom occur; the cylinder will

remain clean for a longer period and the piston rings will not gum or stick. The water tank, however, takes room, adds weight and considerably reduces cargo space. Furthermore, despite careful attention, corrosion and rust will rapidly destroy the motor, especially if sea water is used. The most serious objection, however, lies in the fact that the amount of water injected must be regulated according to load and this necessitates constant attention.

On the other hand, if the intermediate-pressure motor is operated without water injection, the cost of maintenance is low, the mechanism construction simple and little attention is necessary. Its chief operating difficulty lies in the inability to properly time the supply of fuel oil as its injection against the highly compressed air is exceedingly difficult in the short time allowed before ignition takes place.

High-Pressure Type. The advantages of high-pressure motors with self-ignition and injection of fuel oil during the high-compression cycle are practically the same as those of the intermediate-pressure motor without water injection. High-pressure motors, however, are usually operated with an oil chamber and such a type is very economical, has a high mean effective pressure, its cylinders are small, its weight low and it can be started without any preliminary operations. Furthermore, since the fuel oil is not injected against a high pressure the fuel-oil pumps can be of simple design and consequently easily maintained. Like all other motors, however, this type also has its disadvantages, chiefly the fault of design and construction rather than operation. If the size of the oil chambers or atomizer holes be improperly proportioned, fuel-oil consumption will greatly increase. Since this type of motor cannot be started by hand pressure air is therefore necessary and consequently the motor must be manufactured with great care. This of course means a higher initial cost. In operation, the ignition and combustion cannot always be controlled and especially if inefficiently operated preignition will occur.

Four-Stroke-Cycle Motors

Advantages. This type of motor is particularly well-adapted to high-speed work since it has a separate suction and exhaust stroke and thus the cylinder is filled each time with a full and new charge. Compared to a corresponding two-stroke motor it uses less fuel per brake horsepower. Furthermore, it does not employ a scavenging pump, receivers, etc., and the motor construction is therefore simplified and better adopted for continuous hard work.

Disadvantages. The chief objections to this type of motor are its increased weight and the greater space required. On account of the increased number of valves the valve gear is more complicated and noisy. Except with very large output the piston can act as a crosshead and unless the cylinder diameter be greater than 20 in., water cooling is unnecessary. The crank motion of this type of motor necessitates a heavy crankshaft and heavy flywheel if smooth running is to be obtained. Furthermore, the exhaust valves are subjected to high temperatures and occasionally give rise to considerable trouble. This type of motor is exclusively used for the Danish and Dutch merchant marine and also finds a large field in the automobile and aeroplane industry as gasoline and gas engines work as a rule in the four-stroke cycle.

Two-Stroke-Cycle Motors

Advantages. Compared with a four-stroke motor a two-stroke-cycle motor has a greater output per cylinder and everything else being equal, this will usually be about 75 per cent. On account of its greater pressure at the beginning of the compression stroke the weight of the charge can be increased if the stroke volumes are equal. On the other hand, the power is exerted only during three-quarters of the stroke as during the remaining portion exhaust takes place. Thus the total stroke volume is not completely filled at the beginning of compression with a fresh charge, and the result is that for the same cylinder dimensions the output is only 75 per cent greater than for a four-stroke motor. This difference, however, becomes even less for high-speed two-stroke motors since the mean effective pressure is lower. By forced scavenging through the valves the fresh air charge can, however, be made cleaner. In large units only the starting and fuel valves are subjected to high temperatures. In the open-type four-stroke motor, vapor from lubricating oil and exhaust gases can escape into the engine room, thereby causing impure air conditions. This, however, does not occur in a two-stroke motor which has a closed crankcase. Finally, the two-stroke engine is very smooth running because of its more uniform torque.

Disadvantages. The chief disadvantage of the two-stroke motor is its high operating cost. This is due to its higher loss of fresh air charge through exhaust parts and smaller utilization of the working fluid and higher heat loss due to cooling friction and increased pump work. The mean effective pressure is lower because during the working stroke exhaust also takes place. The mean temperature during the cycle is higher than in the four-stroke motor and consequently cooling of the piston is necessary. Furthermore, the piston can act as a crosshead only in small motors; lubricating-oil consumption is greater and the exhaust ports become overheated if not water-cooled. Finally, the stresses exerted on the moving parts are very large and therefore there must be ample sliding and bearing surface. The two-stroke type of motor is chiefly used in vessels where weight, space and first cost are the deciding factors. Its reliability and economy, however, have not been so marked as in the case of the four-stroke motor although in the Scandinavian countries, Germany and Italy it has been used to a considerable extent.

Notes

The exigencies of the war and the reconstruction period are forcing narrow-gage railways into engineering notice in England, where many productive areas are still isolated from the centers of consumption. It is urged that the available material for hundreds of miles of the light railway which was developed so effectively in the zone of communications at the front can now be put down in the remote districts of England by the experts who built similar lines in France, without the complicated legal and parliamentary procedure required to put through a standard-gage line and at much lower first cost and operating expense than main-line railways or highways.

An article describing the ventilation plant of the Simplon Tunnels, published in four recent issues of the *Schweizerische-Bauzeitung*, discloses some of the interesting questions which were considered in the determination of the position and the dimensions of the fans. There is only one ventilation plant for the two tunnels. The northern inlet at Brig was selected for the location of the plant, partly because meteorological conditions proved that the barometric pressure is in general higher at this entrance so that less power would be required for maintaining an air current from north to south than in the opposite direction, and partly also by the fact that the whole organization of the tunnel service was concentrated at that town.

The plan of having the current in each tunnel follow the direction of the train motion was not adopted because it had been observed that, when the air was taken in at Iselle, all the iron in the tunnel structure rusted badly. The reason was that the air at the southern entrance, being warmer and more humid, became cooled and deposited its moisture while traveling in the tunnel. In order to reduce the air resistance to a passing train and the power demand on the ventilation plant, the ventilation is shut down during the northward passage of the train.

Each of the two ventilators in the plant is a fan of $11\frac{1}{2}$ ft. external diameter and 5.13 ft. wide, with a central suction opening $8\frac{1}{2}$ ft. in diameter; six parallel rows of buckets, built of wrought-iron blades and partitions, take up 4.1 ft. of the width of the wheel; the hub is of cast iron. Each fan is directly coupled with an asynchronous three-phase motor which is fed with railway current at 3200 volts and a frequency of $16\frac{2}{3}$.

CORRESPONDENCE

Contributions to the Correspondence Departments of Mechanical Engineering by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

How Can Engineers Be of the Greatest Use to Civilization?

To the Editor:

Engineering depends upon knowledge of facts and upon putting that knowledge into practice.

The exact form that the practice may take is guided by the conditions at the time and place concerned. There may be differences of opinion as to the exact value of those facts because of difficulty in getting perfect measurements, but as to the facts themselves, engineers are agreed.

It does not matter to the engineer whether these facts are found in a book on physics, or natural philosophy, or the first book of science, or whether they are found in an engineer's handbook.

Imagine, if you can, an engineer proposing that the law of gravity for a certain place be established by a vote of the people, or that delegates be appointed who should meet with delegates from other countries to come to a working understanding on a fair and just multiplication table, or that designers should get together and compromise their differences so that the mechanical properties of bodies should be the same in all countries!

There may have been a time when such an attempt could have been made, but if so, it was before there was any general knowledge of the principles upon which engineering is founded.

Many times statements come from engineering sources that engineers do not receive the recognition in the general affairs of the world to which their knowledge and training point. So general are the facts upon which such statements are based that they may be accepted as true, and if they are true there must be a reason for that truth.

Various reasons have been given for this state of affairs, but it has seemed to me that they do not go deep enough to get to the root of the matter.

No man who is educated to the point where he deserves to be called an engineer ever quarrels with the truths, or laws, upon which his profession is founded. In dealing with the circle, for instance, he knows that the diameter and the circumference have a fixed relationship to one another even though he cannot express in figures what this relationship is to absolute correctness, and he knows this, whether he uses 3 1/7 to 1 as the ratio of the circumference to the diameter as being accurate enough for the case in hand, or whether he uses figures which come nearer to the truth.

Even in matters in which the knowledge of the underlying laws is still very incomplete, as with wireless electricity, the engineer never doubts the existence of these laws, and his efforts are always directed to finding them and obeying them, for he is sure that only by so doing can he really succeed.

Knowing so much in his own particular part of the world, how can the engineer avoid the conclusion that the remainder of the universe is founded on just as fixed laws? If he does so conclude, why does he not act in harmony with his conclusions? If he is in doubt in the matter, why does he not investigate in a manner to find the truth?

Is there any evidence that engineers are clearer thinkers in every-day affairs outside of their line of engineering than those who are not engineers? If they are not, why should the public give them a larger part in its affairs? If they are, why does it not show in their position in the affairs in which we all are interested?

In matters such as taxation, one which affects every individual and every community, for instance; or the prohibition of the use of intoxicants; or the choice of candidates for public office; or the enforcement of laws in local affairs; or in the numbers of other things which no one of us can get away from, is the engineer guided by trained reasoning powers which seek out the truth, or is he controlled by his passions, his prejudices and his inherited superstitions, just as are the so-called uneducated?

Unless we, as engineers, can show that our education as engineers does fit us for leadership in these other things, why should the public have any more use for us than it now has?

Of course, it is much more pleasing to think that fault in the matter rests on the public and not on us, but the truth is the thing that will control in this matter, just as it does in engineering matters.

The activities of the members of this Society have gone far beyond our original aims; new boundaries are being thought of and need for a larger vision has been pointed out and a new code for our guidance has been urged. While we are thinking of these things, should we not recognize that all truths are comrades fighting the battles of civilization, whether these truths are religious, political, social or engineering truths, and that all untruth is on the other side, fighting against civilization?

Engineering developed because it sought out, found and accepted things that are the tools of the engineer, and if civilization is to grow and prosper and endure it must rest on a like foundation of truth in all matters that are the tools of civilization.

If the belief that truth of all kinds will finally prevail is not justified, the outlook for the future is surely a dark one. If the belief *is* justified, then honor belongs to those who find and practice truth, and we as a society and as individuals should always be on the side of truth in all of our human activities.

Engineers have numerous handbooks. Go to any of these that you will, and you find that there is perfect agreement in the fundamental principles. If there is any disagreement it is in regard to the best way to apply these principles, but as to the principles themselves there is no disagreement. If any member of any of these engineering societies were to try to start a movement to have a vote taken to adopt something else instead of these foundation principles, he would be expelled and perhaps shut up in an insane asylum; and certainly a person who did not believe in these principles would not be admitted to membership if his beliefs were known.

Why not have handbooks of civilization in which will appear the fundamental truths against which no agitation will be permitted, either under the guise of free speech or under any other form; and if any will persist in working against these truths, why not put him in an insane asylum or deny him the privilege of membership in the society of civilization?

The universe and every atom contained in it is built upon truths, and these truths cannot be altered by any action on our part, but all real progress must be in line with them. Have we vision enough to see this? Have we the courage to look it in the face?

Oil City, Pa.

Regarding the Society's Employment Service

To the Editor:

I was greatly interested in reading the Society Affairs Section of Mechanical Engineering for May, and particularly in the subject, Some of Our Problems.

I note that under this subject mention is made of the Employment Department and the question raised, Shall we continue Employment Work? It is noted that about 7 per cent of the membership was directly benefited last year, and also that some of the members consider this phase of the Society's activities as undignified.

It occurs to me that the Employment Service Department of

the Society has performed a great service to the membership in the past, and the fact that 7 per cent of the large membership of the Society was actually benefited last year speaks well for this department, and, further, it does not occur to me that this service is in any way undignified.

There usually comes a time at some stage in every man's career when he needs assistance in securing proper and suitable employment connections, and it would appear that when the Society through its Employment Service Department has assisted a worthy and qualified engineer to make such a connection, the Society has performed a twofold service: it has assisted a member in securing employment and at the same time has rendered a service to the firm employing him.

C. T. BAKER.

Atlanta, Ga.

TO THE EDITOR:

I want to take this opportunity to express my appreciation of what the A.S.M.E. has done for me, especially in the last few months.

Through the efforts of the Engineering Societies Employment Bureau I have just obtained a position which looks very promising, and the advertisement which I inserted in the current number of MECHANICAL ENGINEERING has brought me a number of replies.

All this has been without extra charge, and it has occurred to me that this must put a heavy burden on the Society. In order that the efficiency and usefulness of the Society may be maintained at its present high standard, I would gladly pay an increase of 25 to 50 per cent in dues, if that should prove necessary.

R. E. NAUMBERG.

New York, N. Y.

WORK OF THE BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 236-239, inclusive, as formulated at the meeting of May 23, 1919, and approved by the Council. In this report, as previously, the names of inquirers have been omitted.

CASE No. 236

Inquiry: Is it permissible under the Rules of the Boiler Code to use commercial open-hearth steel pipe for the heating surface of a special small coil boiler, provided not over $\frac{3}{8}$ in. pipe is used? Also is it permissible to use wrought iron or steel lap-welded extra-heavy pipe for the shell of this boiler, provided the diameter does not exceed 12 in.?

Reply: It was not contemplated that the Boiler Code Rules would be applied to miniature boilers. It is the intention of the Code Committee to prepare a set of Rules for such boilers. Until these Rules are issued, the acceptance of miniature boilers for various classes of service will rest with the rulings of those authorities under whose jurisdiction they may come, without guidance by Code Rules.

CASE No. 237

Inquiry: Is the requirement in Par. 282 of the Boiler Code relative to a lifting device applicable to a $\frac{1}{4}$ in. safety valve designed for operation on miniature boilers? Such a lifting device may be worked out for such a design of small safety valve, but inasmuch as the Rules of the Boiler Code do not apply to valves less than 1 in. in size, it is thought that the lifting device would be unnecessary and undesirable.

Reply: It was not contemplated that the Boiler Code Rules would be applied to attachments for miniature boilers. It is the intention of the Committee to prepare a set of Rules for miniature boilers, and until these Rules are issued, the acceptance of attachments for miniature boilers for various classes of service will rest with the rulings of those authorities under whose jurisdiction they may come, without guidance by Code Rules.

CASE No. 238

Inquiry: Is it permissible under Par. 291 of the Boiler Code relative to water gage glasses, to use a double set of gage cocks? In other words, will a boiler equipped with two sets of gage cocks meet the requirements of the Code for use in saw mills and similar service in the open where there is no protection from injury to the water glass?

Reply: It is the opinion of the Committee that, while Par. 294 permits of omitting the gage cocks if two water glasses are used, a set of gage cocks may not be substituted for a water glass under the requirements of the Rules of the Boiler Code.

CASE No. 239

Inquiry: Is it permissible under the requirements of Par. 194 of the Boiler Code which states that for boilers over 48 in. in barrel diameter, a dome shall be placed on the barrel instead of over the firebox, to place the dome over the firebox on a boiler which has a 50 in. wagon top diameter and a 46 in. barrel diameter? Also, may the holding power of the staybolts be added to the strength of the riveting in the dome seam when figuring the factor of safety?

Reply: It is the opinion of the Committee that for a contracted waist type of boiler, where the barrel diameter is within the limits specified in Par. 194 of the Code, it will be permissible to locate the dome over the firebox. It is not permissible to add to the strength of the riveting in the dome seam the holding power of the stays in calculating the factor of safety.

The value of natural gas as an ideal fuel is now universally recognized and the prevention of fuel waste is of urgent importance to the welfare of the Nation. The Bureau of Mines Technical Paper 209, Traps for Saving Gas at Oil Wells, by W. R. Hamilton, pertinently calls the attention of oil operators to the advantages derived from the use of gas traps for separating and saving the gas from the flow and lead lines of oil wells.

The basic principle of gas-trap construction is to arrest the speed of flow in a chamber that separates the gas and oil. Oil and gas enter the top of a container through one bung, and the gas escapes through another at the top: oil flows out the bottom through a U-tube which provides an oil seal and prevents the escape of gas. This fundamental idea has been modified in various forms to provide for special conditions.

In general, traps might be grouped in three types, upright cylindrical, horizontal tubular, and special. Those of the first type are principally used on wells of small capacity; the second type is specially used for large wells of the gusher type; traps of the third type are used under certain special conditions. Mr. Hamilton describes various devices possessing the characteristics of each of these three general types, with a view to enabling the operator to choose one that will be likely to suit his particular need.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

AERONAUTICS (See also Internal-Combustion Engineering)

Largest Heavier-Than-Air Machine in the World

Tarrant Triplane. Tarrant triplanes, the largest heavier-than-air machines in the world built so far, have been constructed at the Royal Aircraft Establishment at Farnborough. They were designed as bombers and were expected to fly from England to Berlin with a load of sixteen 550-lb. bombs and have a large enough cruising radius to return to England. At present it is the intention to adapt them to commercial flying, as 100 passengers or an equivalent tonnage can be comfortably hoisted within them.

The most distinctive feature of the Tarrant machine is its fuselage, which is made up of a series of braced main rings with lighter rings or formers spaced between, the whole being connected together by a series of longerons running the whole length of the body. These longerons are built up on the Tarrant spar system at the parallel portion of the fuselage and taper down to a single longeron member at the reduced portion. The whole framework is covered by a skin of plywood made of two-ply and varying in thickness upon the different sections of the fuselage.

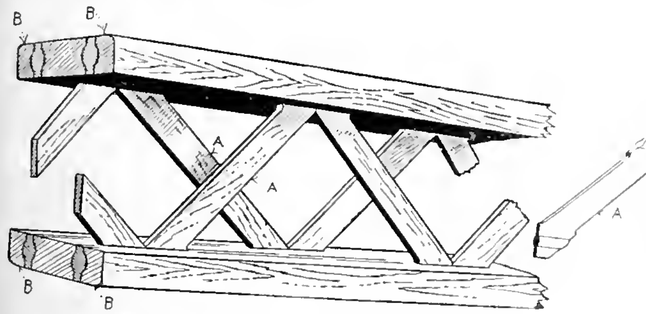

Fig. 1 Tarrant System of Spar Construction

The machine is fitted with six Napier "Lion" engines, each capable of developing 507 b.hp., and with full load a speed of over 90 m.p.h. can be obtained with two engines cut out.

The basic idea of the construction of the more important members of the Tarrant triplane is an adaptation of the braced girder as used in steel bridge work. Instead, however, of riveting the web bracing to the flanges, the construction shown in Fig. 1 has been adopted. The flanges *BB* consist of grooved pieces of wood which are glued on either side of a series of beaded bracing members *A*, the grooves registering with the beads. It is claimed that in this method of construction there is less chance of faulty timber being worked into the machine, for each piece of the girder is small and can be easily inspected. It is also claimed that the time required for seasoning in the Tarrant method of construction is less than usual, owing to the small size of the pieces. The tremendous size of the machine and the character of the mechanism are indicated by Fig. 2. On the left are shown the tanks, engineers' compartment and cockpit. The pilots, engineers and passengers all enter by the same door and are thus protected from risk of being struck by the propellers. In addition to the tanks shown in the figure there are other tanks arranged overhead, where there is also an exit through which the engineers may climb out so as to reach the engines in case of emergency.

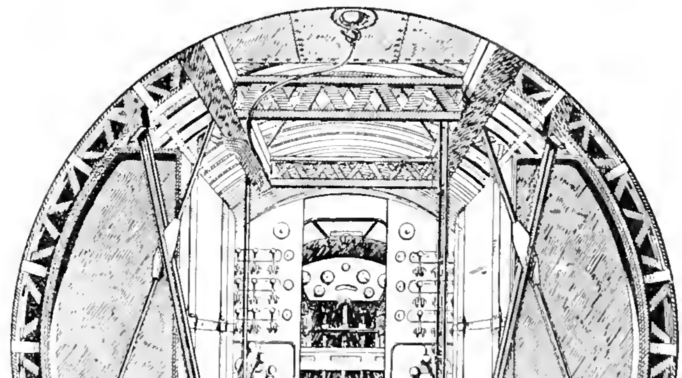

Fig. 2 Tanks, Engineers' Compartment and Cockpit

Fig. 3 shows the engineers' dashboard and entrance to cockpit. The two pilots sit side by side and operate duplicate interconnected controls, in addition to which they have a master control over the engines. For this there are provided a master switch controlling all the ignition circuits and six levers whereby the throttles can be separately adjusted. All other matters connected with the running of the engines are in the hands of the engineers.

The engines are arranged three on each side of the center line and are equipped with the Maybach starting system.

The total weight of the plane with crew, bombs, gasoline and oil is estimated at 44,672 lb. (*The Engineer,* vol. 127, no. 3306, May 9, 1919, pp. 452-454, 10 figs., *dA*)

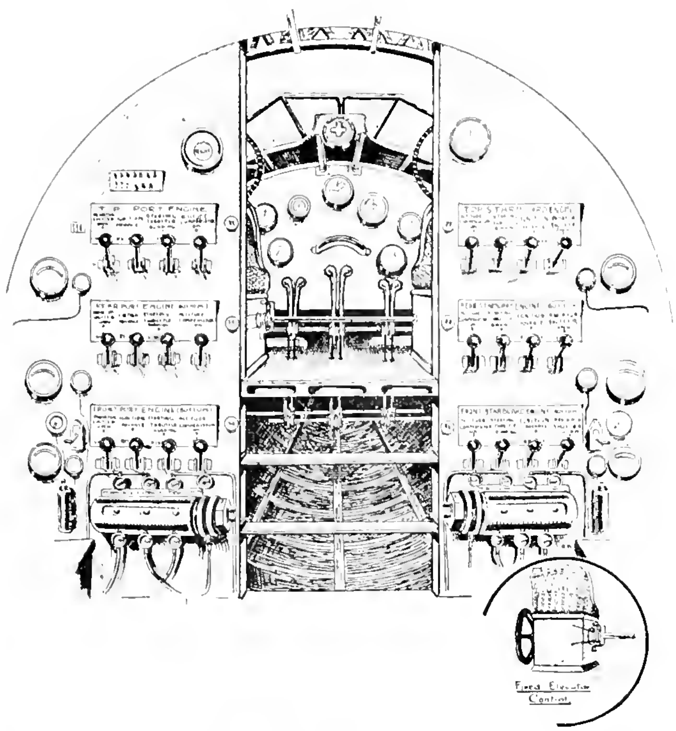

FIG. 3 ENGINEERS' DASHBOARD AND ENTRANCE TO COCKPIT

Moss Supercharger for Airplane Engines

MAINTAINING CONSTANT PRESSURE BEFORE THE CARBURETORS OF AERO ENGINES REGARDLESS OF THEIR ALTITUDE, Leslie V. Spencer. In a previous issue of MECHANICAL ENGINEERING (May, 1919, pp. 476-477) reference was made to superchargers, the aim of which is to maintain a constant content of oxygen in the engine charge regardless of the atmospheric pressure. The

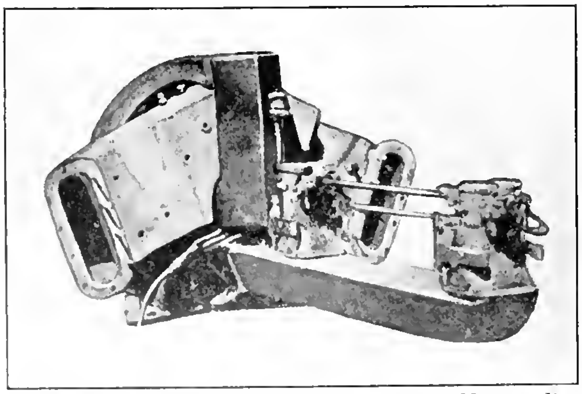

FIG. 4 REAR OF MOSS SUPERCHARGER SHOWING NOZZLE BOX AND INDUCTION SYSTEM

Moss supercharger designed by Dr. Sanford A. Moss, Mem. Am. Soc. M. E., and used on the Liberty-12 belongs to this class of machinery.

In this supercharger the turbine rotor, centrifugal compressor and air impeller are placed on the same shaft and the arrangement is such as to leave the Liberty engine carburetors in the center of the V, connected to the air discharge of the compressor by an induction pipe of generous proportions and rectangular in section.

The engine exhausts are on the outside and the gases are sent to the nozzle box of the turbine by means of substantial, specially designed exhaust headers which connect at their front ends to the flanges on the other side of the nozzle box.

In the Moss machine the nozzles are arranged in a semi-circular plate set into the front side of the nozzle box (compare Fig. 4). This is expected to help in keeping down the temperature of the rotor, since the intense exhaust-gas heat is not being directed to the entire rotor all the time, but to only about one-half of its circumference.

Because of the great fore-and-aft width of the Moss machine it cannot be installed on the Liberty engine with the propeller in its normal position and there has to be used a special propeller flange and hub construction.

A feature of the Moss machine is the water-cooled rear bearing (Fig. 5). A special water jacket surrounds the bearing proper and through it water is circulated from the regular water circulation system of the engine. The machine is also provided with self-aligning bearings to take care of any slight inaccuracy of the position of the rotative parts due to the high speeds and high temperatures encountered in operation.

In confirmation of the precautions taken in the design and the special features incorporated against overheating, the Moss apparatus has never given any appreciable overheating trouble in any operative tests yet conducted. The nozzles, which are subjected to the most severe heating conditions, have shown a slight red color after considerable running, but none of the other parts has become hot enough to reach a visible red. Undoubtedly the successful results obtained in this respect are due largely to the provision for free air circulation around the turbine and an equally free method of exhaust. In the writer's opinion Dr. Moss has been entirely justified in claiming slightly more room at the front of his machine than is allowed by the normal position of the propeller of the Liberty engine, for this permits the design of the apparatus in such a way as to get about as good cooling effects as is possible in the necessarily limited space available. The matter of the heat dissipation is of premier importance in any development work of this nature.

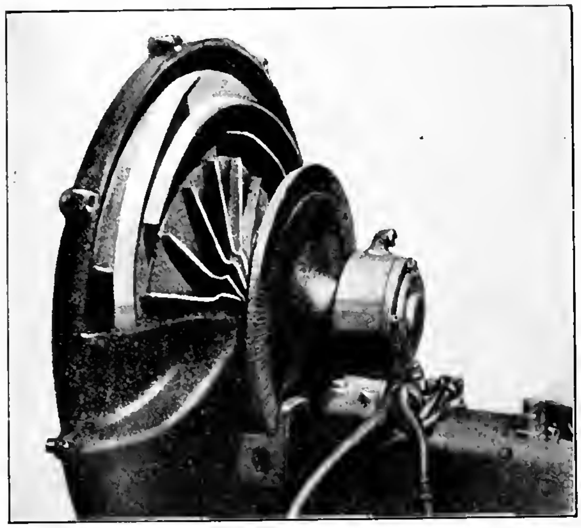

FIG. 5 MOSS TURBINE WHEEL AND WATER-COOLED REAR BEARING

In order to prevent the nozzle box and exhaust manifolds from getting out of shape due to the temperature and the pressure of the gas within, these chambers are internally braced by means of cross-stays which are welded to the casings. This was found necessary due to the fact that the nozzle box must not be allowed to distort to any extent, and in order to maintain a good joint between the nozzle box and the manifold on either side the manifold must be made quite rigid without being heavy. The cross-stays have proved a most satisfactory expedient. (*Aerial Age Weekly*, vol. 9, no. 8, May 5, 1919, pp. 387-389, 4 figs. *dA*)

AIR MACHINERY

Swiss Intercooler for Turbo-Compressors

B. B. C. AIR COOLERS FOR TURBO-COMPRESSORS (*B. B. C. Mitteilungen*, Nov. and Dec., 1918). The present article describes a new (patented) type of cooler for turbo-compressors, manufac-

tured by Brown, Boveri and Co., of Baden, Switzerland, and designed to meet the reduction in the number of cylinders used in the compressor to one. The new device is called an "intercooler," being fitted between the first, second and third groups of rotors of the compressor. The air enters and emerges through special coils so arranged over the groups as not to affect the rotor overall length of the compressor.

The cooling surface of each stage is distributed over two nests of coolers arranged in parallel, which are placed obliquely at both sides of the lower part of the cylinder. This arrangement facilitates cleaning.

The lower parts of the coolers are divided into two parts, which permits of cleaning them while the machine is running; the water chamber of one half can be opened while the other half remains in operation, thus preventing too great a rise in temperature of the successive groups of rotors.

The nests of tubes are generally round, though oval brass tubes are used for heavy loads, in the first and second stages, the tubes being brazed into solid bronze bottoms. The upper bottom plate, with its water chamber, is firmly screwed down to the cylinder, while the end piece of the lower bottom plate is freely movable in a round stuffing box, to allow for expansion of the tubes with temperature.

The cross-sectional area of the air passage between the tubes (the "air gap") is so selected that the heat transmission and pressure drop are at a convenient ratio to the efficiency of the compressor, and the cross-sectional area of the nest assumes a square shape which fills up the round openings in the cylinder as much as possible by omitting the tubes at the corners of the square. This form also permits of the use of round stuffing boxes of minimum diameter.

To compensate for the uneven thermal expansion of single tubes or groups which would give rise to deleterious stresses, the tubes are bent so that each one of them may expand outwards if necessary.

Special distance pieces are fitted to hold the long tubes together and prevent vibration, and other arrangements are provided to eliminate play and displacement of the tubes.

The air and water flow through the tubes on the counterflow principle, i. e., the air outlet and water inlet coincide, the article describing the flow of the two media in the various parts of the cooler.

The tube nests, water chambers and side plates form one unit which can be inserted in the cylinder openings.

The theoretical discussion in connection with the new type of cooler deals with: (1) the transmission of heat and the specific pressure drop; (2) influence of the cooler load on the efficiency of the compressor; (3) comparison of different methods of cooling compressors; and (4) the heat-transmission factors of various types of tubes.

The manufacturers claim that the cooling of their compressors may be said to be satisfactory in all respects, as it provides for the best utilization of the cooling surface by the arrangement of the tubes and by the air velocities and cooler factor obtained. (*Technical Supplement to the Review of the Foreign Press, vol.* 3, no. 10, May 13, 1919, no. 5008, pp. 349-350, *d*)

BUREAU OF STANDARDS

A Simplification of the Inverse-Rate Method for Thermal Analysis, Paul D. Merica. The use of stop watches in taking inverse-rate curves in thermal analysis is described, and it is shown that they may be substituted for the chronograph, which is often used without sacrificing accuracy or sensitivity. One operator is able to record the successive time intervals for the inverse-rate curve, with their aid, and no time is subsequently required for the reading and counting of the chronograph record; the intervals so recorded may be plotted directly. (Abstract from Scientific Paper No. 336)

Behavior of Graphite Eutectoid in White Cast Iron

Notes on the Graphitization of White Cast Iron upon Annealing, P. D. Merica and L. F. Gurevich. The annealing or graphitization ranges of temperature were determined for three different compositions used for car wheels. The temperature of initial precipitation of temper carbon for six hours of annealing was not noticeably affected by variation of sulphur content from 0.10 to 0.20 per cent, or by variation of total carbon content from 3.60 to 3.90 per cent, although the effect of greater carbon content is to narrow the temperature range within which graphitization is complete.

The temperature of beginning precipitation of temper carbon was about 830 deg. for the six-hour period of annealing, and about 725 deg. cent. for the 48-hour period. The maximum allowable temperature, therefore, for the annealing or "pitting" of car wheels is about 725 deg. cent.

After complete decomposition of all free cementite by annealing at from 1000 deg. to 1100 deg. cent. and cooling at equal rates in a laboratory electric furnace, less graphite is found in a specimen cooled from a 1100 deg. than in one of the same composition cooled from 1000 deg. cent. This indicates that graphite separates directly from solid solution upon cooling when its nuclei are already present.

The fact that only 0.20 per cent of combined carbon was found in some specimens after annealing at high temperatures, and cooling slowly in the furnace would indicate either that the graphite eutectoid lies at much lower values of carbon content than has been previously supposed; that there is at those rates of cooling a direct precipitation of graphite eutectoid, or that there is a formation of graphite from pearlite at temperatures directly below that of its formation. (Technologic Paper No. 129)

Results of Tests of Wire Rope

Strength and Other Properties of Wire Rope, J. H. Griffith and J. G. Bragg. The paper presents the results of tests on 275 wire ropes submitted by American manufacturers to fulfill the specifications framed by the Isthmian Canal Commission in 1912. The samples were selected by Government inspectors for acceptance tests of material to be used at the Canal Zone.

The ropes ranged in diameter from ¼ to 1½ in., a few being of larger diameters up to 3¼ in. Over half the specimens were plow and crucible cast-steel hoisting rope of 6 and 8 strands, 19 wires each. The remainder were galvanized steel guy rope and iron tiller ropes of 6 strands 7 wires, and 6 strands 42 wires, respectively.

The investigation was made primarily to determine the tensile strengths of the ropes. Much of the experimentation was of a supplementary character—to determine the general laws of construction of the rope as the basis of the interpretation of their physical behavior under stress. A comparative analysis was made of the chemical constituents of steel, rope fibers and lubricants of plow ropes submitted by different manufacturers.

The wires at the ends of specimens were "frayed out" to form a "broom." These were inserted into molds, into which molten zinc was poured so as to form conical sockets for connection to the testing machines. Most of the tensile tests were made on a 600,000-lb. Olsen testing machine, the ropes of large diameters being tested on the 1,200,000-lb. Emery machine. Stress-strain measurements were made on over half the specimens. Numerous tests of individual wires were conducted in tensile, bending and torsion machines. The strengths of the cables were studied in connection with their modes of construction, the strengths of their component wires, and the types of fractures which were presented.

The homologous linear dimensions of the strands, wires and fiber cores were found to vary in direct proportion to the diameters of the ropes. The diameters of the strands and fiber cores were generally ⅓ the diameter of the rope. The mean pitch or lay of the strands was 7½ diameters. The mean lay of the wires was 2¾ diameters. The mean diameter of the wires was expressed by the equation:

$$d = KD/(N+3)$$

where d = diameter of wires
D = diameter of rope
N = number of wires in outer ring of wires of a strand

$$K = \begin{cases} 1.0 \text{ for hoisting and guy rope} \\ 0.8 \text{ for extra flexible } 8 \times 19 \text{ hoisting rope} \\ 0.33 \text{ for tiller rope.} \end{cases}$$

The aggregate cross-sectional areas of the wires was expressed approximately by the equation:

$$A = CD^2$$

where C = 0.41 for 6 x 19 plow steel hoisting rope
= 0.38 for 6 x 19 crucible steel hoisting rope
= 0.38 for 6 x 7 guy rope
= 0.35 for x 17 plow-steel rope
= 0.26 for 6 x 42 iron tiller rope.

It was found when the maximum loads determined from tensile tests were platted as functions of the diameters of the ropes that the curves bounding the lower frontiers of each zone comprising the observed values were in close agreement with similar curves platted from the minimum strength stipulated in the specifications of the Isthmian Canal Commission of 1912. These strengths were also in approximate agreement with the standard strengths recommended in 1910 by the manufacturers from the results of their tests of cables similarly classified. The minimum strengths found from the present investigation are given by the following empirical equation:

$$\text{Load} = C \times 75{,}000D^2$$

where D = diameter of wire rope in inches

$$C = \begin{cases} 0.9 \text{ to } 1.1 \text{ (mean, about 1.0) for } 6 \times 19 \text{ plow-steel cables} \\ 0.8 \text{ to } 0.95 \text{ (mean, about 0.9) for } 8 \times 10 \text{ plow-steel and } 6 \times 19 \text{ crucible cast-steel cables} \\ 0.3 \text{ to } 0.4 \text{ (mean, about 0.35) for iron tiller and steel guy rope.} \end{cases}$$

The modulus of the rope calculated from stress-strain measurement was found to vary from 3,000,000 to 9,000,000 lb. per sq. in., depending upon the diameter and class of cable.

Plow-steel ropes were selected for comparative analyses of the constituent materials. In the chemical analyses the carbon content ranged from 64 to 96 per cent, with a mean of about 75 per cent. The manganese ranged from 25 to 68 per cent, the silicon from 11 to 24 per cent. The percentage of phosphorus and sulphur was relatively low. In certain cases the steel of the filler wires was softer than the main wires.

The fibers used in making the core of the rope were estimated as manila, jute, istle, mauritius, manila fiber alone being employed by certain manufacturers. The preservative and lubricants on the cores were composed of wood and vegetable tars, petroleum products, and fish oil, the practice varying somewhat.

There was a reasonable uniformity in the strengths and elongations of the wires from a particular cable, but a larger variation in the strengths of the wires from cables of different manufacturers. This was probably due to the fact that different grades of plow steel were used by the several manufacturers in meeting the provisions of the specifications.

The cables developed from 72 to 90 per cent of the aggregate strengths of the wires. The upper limit of the ratio of the strength of a rope to the strengths of its wires was found from theoretical considerations to be 89.2 per cent for 6 x 19 plow-steel cables. The differences between the results of the theoretical analysis and the practical tests were largely attributed to different strengths and degrees of ductility of the wires, this causing an unequal distribution of the load among the strands with overstressing of certain strands near the point of failure. (Technologic Paper No. 121)

The Effect of Rate of Temperature Change on the Transformations in an Alloy Steel, H. Scott. Cooling curves taken on an air-hardening steel of the high-speed tool-steel type show two critical points on cooling from 920 deg. cent., one occurring at about 750 deg. cent., accompanied by the precipitation of the hardening constituent, the carbide, and the other on fast cooling at about 400 deg. cent., under which condition the carbide remains in solution as martensite. On cooling at intermediate rates both transformations are observed, and the constituents, troostite and martensite, are detected by the microscope. A transformation is observed on the heating curves taken following a fast cooling, which is manifested by an evolution of heat ending at about 645 deg cent., and which represents the precipitation of the carbide held in solution as a result of the previous rapid cooling. The re-solution of the carbide under those conditions occurs at a temperature some 10 to 15 deg. cent. higher than after a slow cooling.

The conclusions drawn support the twenty-year-old theory of Le Chatelier that martensite is a solid solution of carbide in alpha iron. (Abstract from Scientific Paper No. 335)

ENGINEERING MATERIALS

Examination of Materials by X-Rays. Report of the general discussion at a joint meeting of the Faraday Society and the Roentgen Society, held April 29, 1919, Sir Robt. Hadfield, Mem. Am. Soc. M. E., presiding.

Prof. W. H. Bragg, of the University College, London, showed the extraordinary sensitiveness of the X-ray method of investigation. The transparency of a material to X-rays decreases as the atomic weight of the material increases. Heat has no influence, and a red-hot casting gives the same radiograph as a cold casting. Photographs of good and faulty castings and welds were exhibited, the tool marks showing quite distinctly. Considering how minute the difference in thickness due to tool marks is, this indicates the remarkable sensitiveness of the method. An attempt was made to explain this high sensitiveness. The question as to whether hard or soft X-rays should be used was next taken up by Professor Bragg. For penetrating through the material the rays should be hard, but in that case they also penetrated through the plate, which is not an advantage. That action was due to the liberation of electrons which darted to and fro among the surrounding atoms until their energy was spent. In the emulsion, electrons were set in motion mainly through absorption of X-rays by the silver and bromine, and that action might be reinforced by putting heavy atoms into the emulsion. Some experimenters placed a thin lead sheet on the film, so that the electrons generated in the lead struck back into the photographic plate. The variation in the absorption of rays of different wave lengths, studied by the Duc de Broglie and others, suggested a further consideration. As wave length increased the absorption by a given substance also increased: but at a certain value, critical for each substance, the absorption suddenly dropped, to rise again steadily afterwards. There was, therefore, a "step down" in the photograph—it should not be called a band—marking the critical wave length for silver. A similar "step up" on the side of short wave length would be obtained by interposing an absorbing screen, say of antimony or some other metal, in the path of the rays. That "antimony line" was so sharp that it might serve for a new method of spectroscopic examination of the constituents of a material. We might also put some special material in the emulsion and choose X-rays intermediate between the actual value of this material and of the casting under test; but this did not appear practicable.

A paper by E. Schneider on "The Industrial X-Ray Examination of Methods at the Laboratories of Messrs. Schneider & Co., Le Creusot, was read.

Two German papers have been translated and presented in abstract; one of these papers by Doctor Respondek of Hallensee, near Berlin, outlined the principles covering the penetration of metals by X-rays, and the other by F. Janus of Munich and M. Rettchen of Cologne explained the investigation of metals by means of X-rays. (*Engineering*, vol. 107, no. 2783, May 2, 1919, pp. 576-578, 1 fig., *e*)

HYDRAULIC ENGINEERING

Experimental Data on Conditions Covering Surge Pressures in Pipe Lines

Surge Pressures in Pipe Lines, Ralph Bennett. Description and data of tests made to determine the actual effect of varying the conditions on two pipes equipped with air chambers and of changing choke-gate areas. In these tests a simple apparatus was

used giving a time-pressure record of the variations which took place at shutdown in these pumping lines, the lines on the test being 18 in. and 24 in. in diameter. Further, the 18-in. line was equipped with the plain air chamber, while the 24-in. pipe was without any protection against shock.

In these tests the pencil mechanism of a steam indicator was so arranged that it made a record on a strip moved by the clockwork train taken from a high-speed recording voltmeter. The apparatus gave records sufficiently accurate for the purpose, though subject to the usual disadvantages of the steam indicator when used on water.

The indicator was connected at the base of the air chamber (Fig. 6), the reading being the pressure of the line. In one case the instrument was transferred to a point above the diaphragm to obtain a record of tank-pressure changes, and the curve was superimposed on the pipe-line curve secured from an otherwise similar test (Fig. 8*F*). Thus curve shows graphically the time and intensity relations of the internal and external pressures when an almost perfect damping is attained in a single swing.

The vertical scales shown on the curves are those corresponding

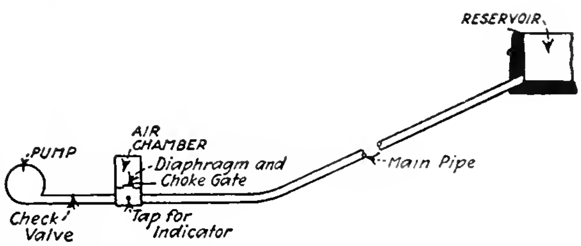

FIG. 6 TEST APPARATUS FOR RECORDING SURGE PRESSURES IN PIPE LINES

to the spring used. Owing to indicator friction and secondary pressure disturbances the curve peak values may vary considerable from actual values.

The horizontal scale of time must be averaged, as minor irregularities of drum movement affect the record. The time given for the waves is that of the half-wave after completion of shutdown when the column is vibrating as a free or loaded pendulum.

The 18-in. line was of riveted steel, average thickness 0.087 in., total length 3187 ft. The maximum head was 240 ft. (104 lb. per sq. in.) and the grade uniform without sharp bends or obstructions. The air chamber at the pump is 36 in. in diameter and 10.5 ft. long above the line, which passes directly through it. The pump delivering by test 954 gal. per min. gave a line velocity of 0.2 ft. per sec.

Shutdown tests were made on this line using varying quantities of air in the chamber. The results of some of these tests are given in Fig. 7 and in the original article in a table.

Further tests were made on the 24-in. pipe of a total length of 6791 ft. and with a maximum head of 160 ft. (70 lb. per sq. in. including friction) and uniform grade without sharp bends or obstructions.

The air chamber is 48 in. in diameter with 15 ft. effective height and a line velocity of 1.33 ft. per sec. is used.

The choke valve on the pump (two-stage centrifugal) was an

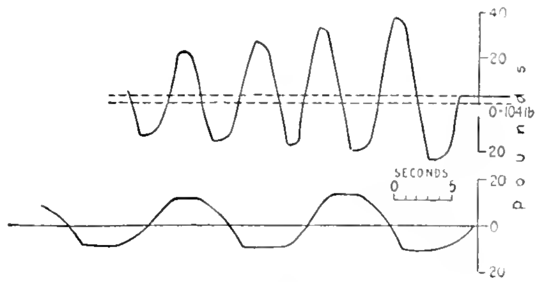

FIG. 7 GRAPHS FROM TESTS ON 18-IN. PIPE LINE

egg-shaped plunger controlled as to speed of closing by a bypassed plunger. The free actual was as rapid as that of a swing check.

On this line tests were made for numerous volumes of air and for different choke openings.

Fig. 8*A* shows the card obtained with 67 cu. ft. of air and a 25.87-sq. in. choke. Under this condition, the fall of pressure at shutdown is very severe, and the oscillations die down very quickly. The condition desired is one in which the greatest possible absorption of energy occurs across the choke from the instant of shutdown. The best condition occurs when the first half-wave (in this case negative) is the one in which the greatest loss occurs. The ability of the line to stand reduction in pressure will frequently limit the possible control.

Note on this curve the great distortion of the fundamental wave of the shock from the check valve. This superimposed pressure may at times become very serious, but, as stated above, any attempt to control it by slow valve action is a move in the wrong direction. Better results would be obtained by a loaded valve.

Fig. 8*B* was obtained with the same air content, 67 cu. ft., and a 32-sq. in. choke. The check-valve disturbance is much as before. The indicator was put on the line before the pump was started, and the entire cycle from standstill to standstill is shown. Note that the shock due to the rapid start of the pump is more severe than is that due to the shutdown surge.

The quantity of air and the closeness of the choke can be varied within limits with about the above results, but any considerable decrease in the amount of air reduces the ability of the tank to absorb energy and increases both the pressure peaks and the

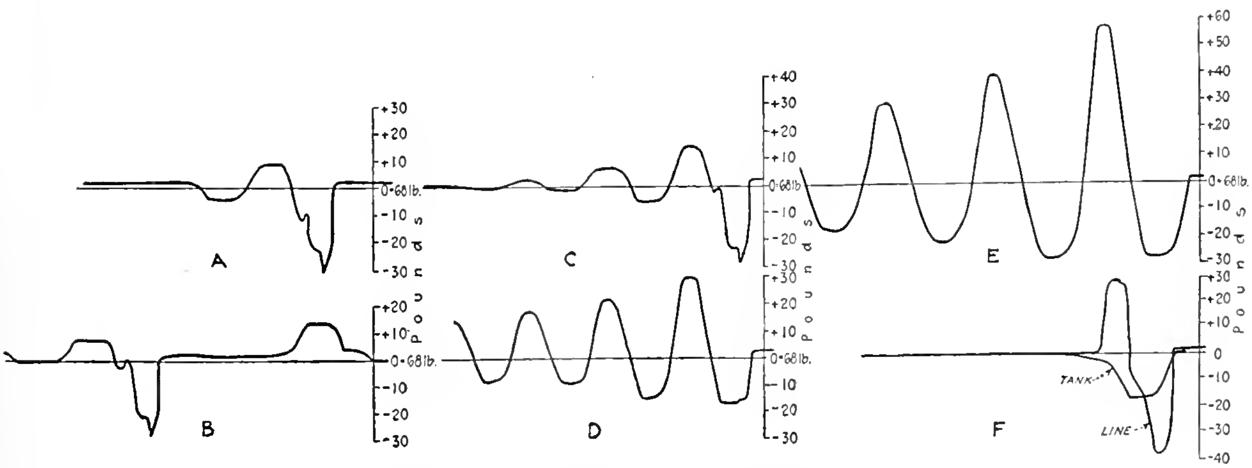

FIG. 8 GRAPHS FROM TESTS OF 24-IN. PIPE LINE

(Above—air, 14 cu. ft.; below—air, 118 cu. ft.)

(*A*—air, 67 cu. ft.; choke, 25.9 sq. in.; *B*—air, 67 cu. ft.; choke, 32.0 sq. in.; *C*—air, 35 cu. ft.; choke, 25.8 sq. in.; *D*—air, 35 cu. ft.; choke, 45.0 sq. in.; *E*—air, 90 cu. ft.; choke, 68.0 sq. in.; *F*—superimposed tank and line pressures.)

number of undulations required for full absorption of the energy in the water. Curves in Figs. 8C and 8D show these effects very clearly. Fig. 8C shows good control with 35 cu. ft. of air and a 25.8-sq. in. choke, while Fig. 8D, with the same volume, produces an excessive shock.

If the tank contains ample air but is too freely connected to the line, a condition results similar to that shown in Fig. 8E, which was taken when the air supply, 90 cu. ft., was more than ample for full pressure control but with no excessive opening, 68 sq. in. (*Engineering News Record,* vol. 82, no. 2, May 29, 1919, pp. 1048-1050, 9 figs., eA)

INTERNAL-COMBUSTION ENGINEERING (See also Aeronautics)

Oscillograph Tests of Various Types of Spark Plugs

SPARK-PLUG EFFICIENCY, Maj. A. M. Low. Data of tests on the intensity and duration of ignition sparks and conditions affecting them.

The writer states that pointed electrodes are ape to produce brushing, which may sometimes be so great as to prevent the engine being started.

There is a simple experiment of passing a spark through water by insulating the electrodes so thoroughly by means of glass that the spark has no other option.

In the case of the plain 2-point type of plug the current jumps

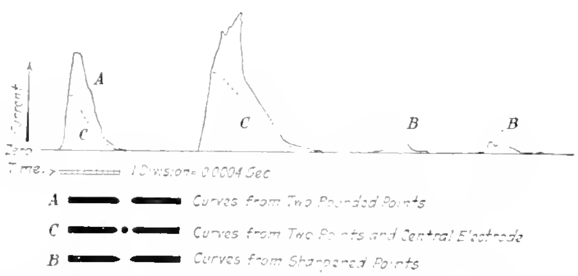

FIG. 9 OSCILLOGRAPH CURVES FROM SPARK PLUGS OF VARIOUS TYPES

the gap, but a very large proportion crosses as brush discharge and a great deal of efficiency is wasted. With the object of showing this, the author has taken a large number of photographs of the current passing, showing also the duration of the spark or spark and arc. These photographs have been reproduced in the form of diagrams, which are all drawn to scale in Fig. 9. At *A* the spark current is shown between two plain points, while in *B,* in which the plug points are sharpened, the duration and relative value of the current is much less. *C* shows the action of the plugs having a central plain electrode and two wings. The duration of the spark is the same as in *A,* but the current is slightly reduced, proving that two plain gaps in parallel are liable to waste current, as brushing occurs if the energy cannot get across the gaps with sufficient rapidity.

Fig. 10 is intended to show the fallacy of the plan if it is possible to obtain a ring of sparks. The author believes that under compression the current merely takes the path of least resistance, giving one spark at a time but at different places around the gap.

At *B* the current between the electrodes of the plate and point type of plug is shown to be high and of good duration. Fig. 11 shows the effect of two plates or two cups and points, while another figure represents the effect of three wings and one central electrode.

The plate type of plug will often give very good results if the body be not used to form one of the plates, as its large area leads to condensation and difficulty in starting, though for high-speed work it is good. In Fig. 10, *A,* the dotted line represents the current between a point and cup. If the cups are duplicated as in Fig. 11, *A,* the duration is slightly diminished and the current increased, proving that even a single cup and point waste current.

These curves have been obtained by means of a plug or gap connected in series with a Duddell oscillograph.

With almost any plug, the smaller the gap the higher is the amplitude of the current. The duration is also longer so that there is not much to be gained in having the points wide apart, though for high speed it is sometimes of advantage. While this suggests that a variable gap might be used, the author has made a good many tests with a variable-gap plug but the results obtained did not justify the increased complication.

Tests with the manograph on the engine and an oscillograph in circuit with the plug, indicated that more than two sparks per cylinder does not improve efficiency and that the temperature of the sparks which makes the first period of ignition rapid and avoids cooling of the heated particles is of much more importance than the distance between two sparks within the cylinder.

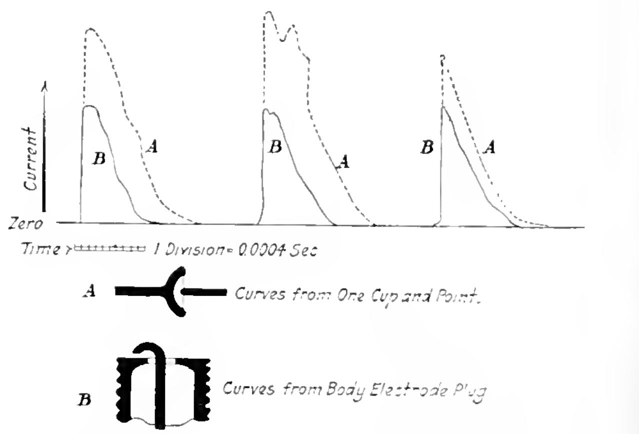

FIG. 10 OSCILLOGRAPH CURVES FROM SPARK PLUGS OF VARIOUS TYPES

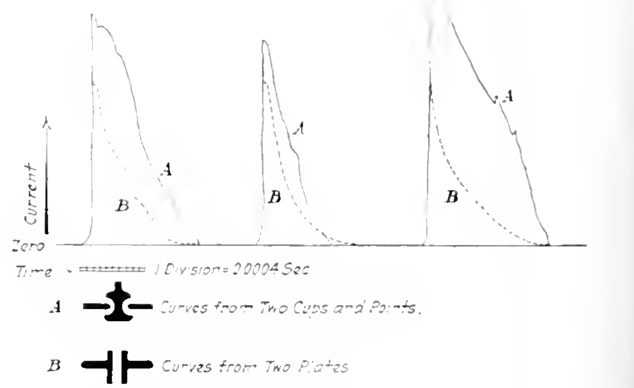

FIG. 11 OSCILLOGRAPH CURVES FROM SPARK PLUGS OF VARIOUS TYPES

It is only the very first production of the spark that is affected by the shape of electrodes, so that it is the first half of the spark that is of such importance. Different kinds of plugs may meet different requirements. The direction in which the current passes is extremely important and it was this that first led to the introduction of the cup system. (*The Autocar,* vol. 42, no. 1228, May 3, 1919, pp. 655-658, 6 figs., *e*)

STARTERS FOR LARGE MOTORS. Description of various starters, chiefly with reference to electric motors such as powder-cartridge type, auxiliary gas starters (like acetylene), compressed air, and electric starters.

An interesting type described is the Herzmark starter. Two cylinders of the engine are filled with carbureted air compressed to 5 kg. per sq. cm. (= 71 lb. per sq. in.). One of the cylinders is at the ignition point and the other in compression stroke, both being in equilibrium. Then by means of a very simple apparatus, ignition of the mixture in one of the cylinders is produced directly

by a magneto spark. The apparatus consists of a triple-action pump, taking from the carburetor a very rich mixture. A small distributor located behind this pump and carrying as many electric coils as there are cylinders indicates which of the cylinders is at the ignition point. An electric connection from a dry-cell circuit with the camshaft acts on the coil which corresponds to it. After a certain number of pump strokes which vary in accordance with the cylinder volume of the engine, all that is necessary is to bring the little movable handle of the distributor over the active coil and apply the catch in order to deliver automatically the mixture into the proper cylinders.

The pump is located right at the pilot's hand and is connected to the engine by two small tubes so that the engine may without any inconvenience be placed at a distance of 25 to 30 ft. from the pump.

It is stated that the starter is of simple construction, quite light (4 kg. or 8.8 lb.) and that it occupies little space (40 cm. by 12 cm. = 15.7 in. by 4.7 in.).

The original article has an illustration of this starter, too indistinct, however, to permit reproduction. (D. J., in *L'Aerophile*, vol. 27, no. 34, Feb. 1-15, 1919, pp. 45-46, 1 fig., *d*)

LUBRICATION (See also Air Machinery)

Practical Data on the Lubrication and Cleaning of Air Compressors

Proper Lubrication of Air Compressors, H. V. Conrad. To be satisfactory, lubrication of air-compressor cylinders should first reduce friction to a minimum, and, second, eliminate as far as possible carbonization of the oil.

The formation of excessive carbon deposits is apt to be due to use of improper oil such as oil of to great a viscosity; use of too great quantities of oil and failure to provide a proper screen over the air intake of the compressor, thus allowing free entrance of dust (coal dust being especially undesirable). Besides the usual objections to carbonization such as sticking of air valves and choking of air passages in the case of air-compressor cylinders, there is a further menace of fire. Carbon particles may become incandescent and cause a fire by coming in contact with oil vapor given off by lubricating oil.

The paper discusses the qualities of various lubricating oils and a basis for making a selection of the proper oil. In particular, data are given on the properties of paraffine-base and asphaltic-base lubricating oils.

As regards the question of quantity of lubricating oil, it is said that while it depends to a certain extent on the viscosity of the oil, heat of compression and size of cylinder in general, it may be stated that after the cylinders have acquired smooth and polished surfaces the quantity should be reduced to the lowest limit. Table 1 is given as a basis for determining the quantity of oil used. The resnlts in the last column are based upon the assumption that under average conditions of temperature and usual range of oil viscosities a pint of oil will contain an average of about 16,000 drops.

For cleaning the air-compressor system and removing carbon it is recommended to use only soap suds. A good cleansing solution is made of 1 part soft soap to 15 parts water. These suds should take the place of oil for a few hours and be fed into the air cylinders about once a week, either by means of a hand pump or through the regular lubricator at a rate about ten times as rapidly as that of the oil.

For cleaning the air receiver and piping a method is suggested, shown in Fig. 12, where a receptacle made of 6-in. pipe is set on top of the discharge pipe.

A cleansing liquid recommended consists of 1 lb. of Red Seal lye to 18 lb. of water. This mixture is passed into the discharge line at the rate of 60 or 70 drops per min. while the compressor is running.

To use the arrangement shown close cocks *A* and *G*, open valve *C* and fill compound through funnel *D;* when chamber *E* is filled, closed valve *C*, open cocks *G* and *A* and regulate feed by valve *B*.

TABLE 1 QUANTITY OF AIR-CYLINDER LUBRICANT REQUIRED PER 10-HOUR DAY

Diameter of Cylinder, in.	Size of cylinder, in.	Displacement per minute, cu. ft.	Piston speed, ft. per min.	Sq. ft. of cylinder wall swept by piston	Drops oil per min.	Drops oil per 10 hr.	Sq. ft. oiled per drop	Pints of oil required per 10 hr.
8	8 × 8	120	344	718	1	600	718	0.0375
12	12 × 12	320	408	1230	2	1200	613	0.0750
18	18 × 18	880	496	2340	4	2400	585	0.1500
24	24 × 24	1730	550	3450	6	3600	575	0.2250
30	30 × 30	2940	600	4700	8	4800	590	0.3000
36	36 × 36	4550	644	6070	10	6000	607	0.3750
42	42 × 42	6700	696	7600	12	7200	633	0.4500

Figures of last column are based upon estimated 16,000 drops per pint of oil at 75 deg. fahr.

The oil should be fed at the rate of about 70 drops per min. (*The Blast Furnace and Steel Plant*, vol. 7, no. 5, May 1919, pp. 224-226 and 242, 1 fig., *gp*)

MACHINE SHOP

Theory of Tolerances and Comparison of Symmetrical and Asymmetrical Systems

Tolerances in Mechanical Construction, A. C. An article based on a publication by Doctor D'Ailly of the C. E. Johansson Gage Company.

There are two kinds of tolerances, the theoretical and the practical. The theoretical tolerance comes from the imperfection of our instrnments and our senses and the more the appliances and processes for checking are improved the more the theoretical tolerance may be reduced, but it will probably never be entirely eliminated.

In manufacturing it is usually entirely unnecessary to strive to attain the limits of theoretical tolerance and a lesser precision known as practical tolerance is as a rule sufficient.

Graphically, the regions of tolerance may be shown in the following manner: Assume that a is the nominal value of the required dimension—for example, the theoretical diameter of a lot of shafts; $x_1, x_2, \ldots x_n$ are the real values of the diameters of these shafts; and that $y_1, y_2, \ldots y_n$ are the numbers of shafts which actually have the diameters $x_1, x_2 \ldots x_n$.

From the calculus of probabilities it is found that the relation between x and y is expressed by the function

$$y = ke^{-h^2(x - a)^2}$$

where e is the base of the Napierian system of logarithms and k

and h are coefficients depending on the perfection of the methods of machining employed in each instance. No matter, however, what the values may be, the representative curve for this equation tends to assume the form shown in Fig. 13; that is, the curve is always symmetrical with respect to the ordinate OY, for which $x = a$.

It is easy to show on this curve the region of theoretical tolerance. Let $\pm \varepsilon$ be the magnitude of theoretical tolerance expressed in the same units as a; the ordinates corresponding to the abscissæ $a + \varepsilon$ and $a - \varepsilon$ indicate the sectioned area in Fig. 13 symmetrical with respect to the ordinate of $x = a$, which represents the region of tolerance, so that all the shafts of which the diameter lies between $a + \varepsilon$ and $a - \varepsilon$ correspond to points of the curve comprised between A and B. The same graphical representation applies to practical tolerances. As a matter of fact, shafts accepted by the inspection are, by the very definition of practical tolerance, those of which the diameter does not differ from a by more than a certain predetermined tolerance.

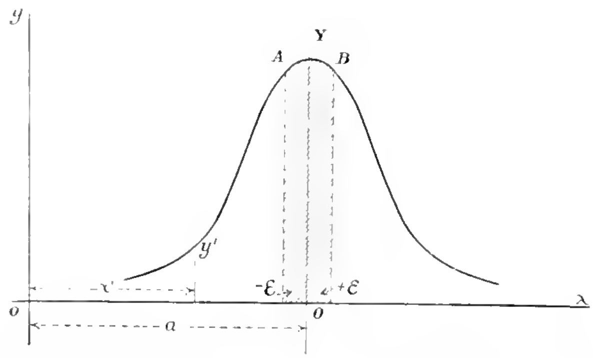

FIG. 13 GRAPHICAL REPRESENTATION OF REGIONS OF TOLERANCE, SYMMETRICAL SYSTEM

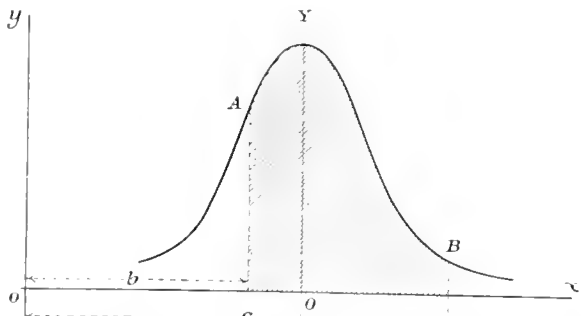

FIG. 14 GRAPHICAL REPRESENTATION OF REGIONS OF TOLERANCE, ASYMMETRICAL SYSTEM

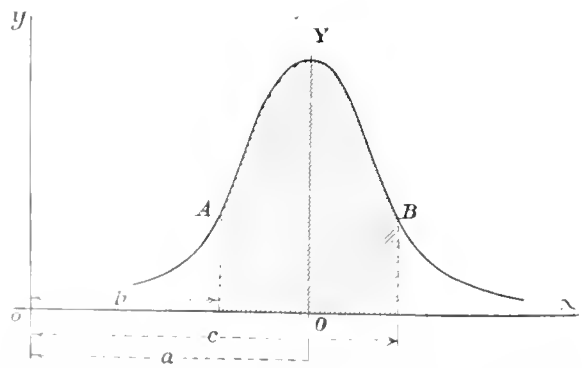

FIG. 15 RELATION BETWEEN THEORETICAL AND PRACTICAL TOLERANCES

Thus, let b be the minimum acceptable diameter and c the maximum (Fig. 14). The region of practical tolerance AB is here also represented by a cross-sectioned area comprised between $x = b$ and $x = c$. If a is the average between b and c the region of practical tolerance will be like that of theoretical tolerance, symmetrical with respect to the ordinate $x = a$. However, the designer may or may not adopt such a symmetry, and in what follows will be presented some of the advantages of symmetrical tolerances.

The whole purpose of tolerances is to permit a correct adjustment and good operation of assemblies constituting a machine. These assemblies may be such as to permit no play between the parts, or such as to require a certain greater or lesser amount of play. For example, in Fig. 16 is shown a rotating shaft and its journal, an assembly in which a certain predetermined amount of play is necessary.

Let us say that t_1 and t_2 are respectively the tolerances for the diameter D_1 of the shaft and the bore D_2 of the bearing. The shaft may then have a diameter which varies between D_1 and d_1 and the bearing may have bores varying from D_2 to d_2. In the first case the minimum play will be j; in the second case the maximum play will be j' and it is obvious that $j' - j = t_1 + t_2$. In other words,

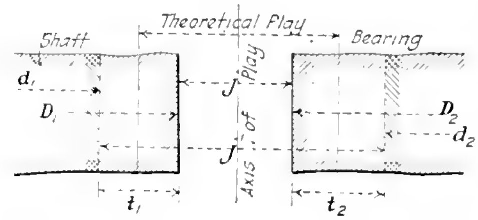

FIG. 16 REGION OF TOLERANCE AND PLAY BETWEEN THE SHAFT AND ITS BEARING

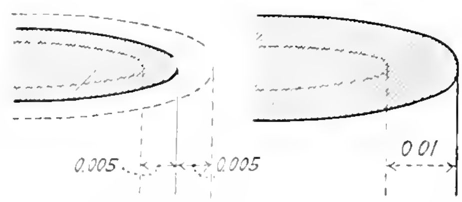

FIG. 17 SYMMETRICAL AND ASYMMETRICAL TOLERANCES

the total tolerance T or the play permitted is the same as the tolerances of the pieces which have to be assembled.

Symmetrical and Asymmetrical Tolerances. After the tolerance for a given piece has been selected it may be used either on the symmetrical or on the asymmetrical system. For example, let the nominal diameter of a shaft be 100 mm. with a tolerance of 0.01 mm. On the symmetrical system this tolerance will apply to the range from 99.995 mm. to 100.005 mm. In the second case there may be a difference in the permitted dimensions above and below 100 mm.; for example, 99.997 mm. to 100.007 mm. There may even be given a range from 99.990 mm. to 100.000 mm., in which case the entire tolerance will lie on one side of the given dimension.

The diagrams of Fig. 17 show at once that the symmetrical system, under equal conditions of manufacture, is more exact than the asymmetrical, because the permissible deviation of diameter is at most one-half of the tolerance, while in the asymmetrical system this deviation may be equal to the entire tolerance.

On the other hand, if, in an assembly such as, for example, a shaft and a bearing, it is desired to reduce the relative tolerance between the shaft and the bearing without varying the theoretical play, then (as apparent from Figs. 18 and 19) in the case of the symmetrical system (Fig. 18), the nominal diameter of the pieces is not altered by the change, and hence the nominal magnitudes on the drawings do not have to be changed when production with a

large tolerance (Case I) is changed to production with a smaller tolerance (Case II).

On the contrary, in the asymmetrical system the passage from Case I to Case II involves a change in the nominal diameter D equal to half the difference between tolerance t_1 and t_2, which can be seen by examining the left side of Fig. 19. In a shop this would involve remaking the drawings and indicating the nominal dimensions in complicated decimal fractions instead of in round figures.

Another case may be cited where the advantage of the symmetrical system is very appreciable. This is the case where it is desired in a lot of pieces, such as shafts, passed with the tolerance t, to carry out a new inspection and pass only the pieces satisfying a much smaller tolerance, for example, $t/2$. This may actually occur in course of production when the shop has a certain amount of completed stock on hand, and suddenly the market

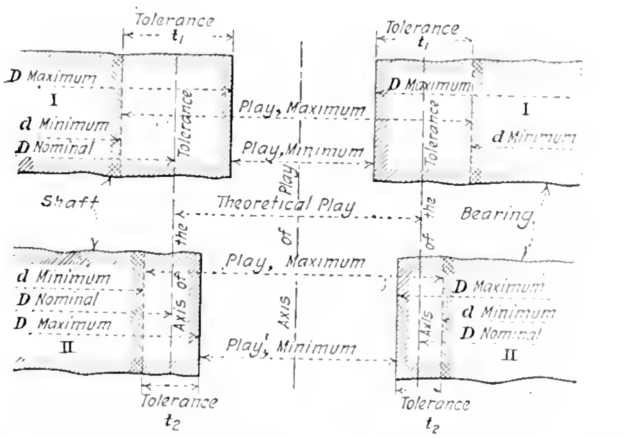

FIG. 18 VARIATION OF TOLERANCE WITH THE SYMMETRICAL SYSTEM

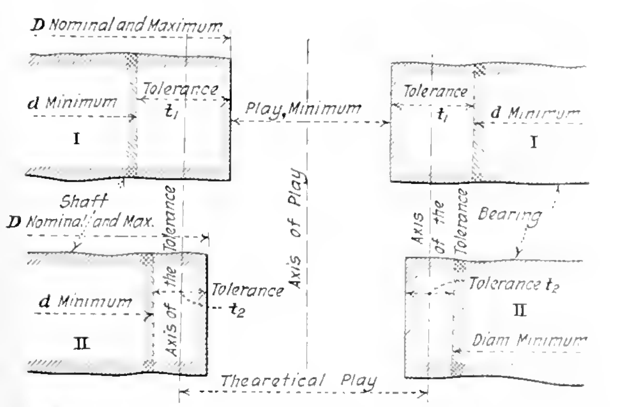

FIG. 19 VARIATION OF TOLERANCES WITH THE ASYMMETRICAL SYSTEM

begins to demand a smaller tolerance than the one which was current previously.

With this in mind the symmetrical and asymmetrical systems are compared, the tolerance being first t and then $t/2$ (Figs. 20 and 21).

The first to be considered (Fig. 21) is the scheme with the shaft adjusted on the basis of symmetrical tolerance. The different diameters which have been considered in this case are:

D, or nominal diameter corresponding to the axis of symmetry OY and the region of tolerances;

D_1, or maximum diameter, and d_1, or minimum diameter corresponding to a tolerance t;

D'_1 and d'_1, maximum and minimum diameters corresponding to a tolerance of $t/2$. The whole figure is symmetrical with respect to the axis OY.

The writer next plots the curve

$$y = ke^{-h^2(x-D)^2}$$

(the constant a of the general equation given above represents in this instance the nominal diameter D) of which the axis of symmetry is likewise OY since it corresponds to the nominal diameter D; the regions of tolerance corresponding respectively to t and $t/2$ and defined by the ordinates Aa and Bb for tolerance t and by Cc and Dd for the tolerance $t/2$. These two regions have in common the zone shaded by intersecting lines with the area $2S$.

The same operation (Fig. 21) may be carried out for the case of a shaft machined on the basis of asymmetrical tolerance. Here the tolerances t and $t/2$ are considerably below the nominal

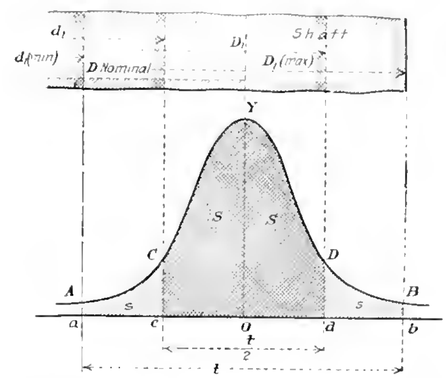

FIG. 20 GRAPHICAL REPRESENTATION OF THE REGIONS OF TOLERANCE WITH THE SYMMETRICAL SYSTEM

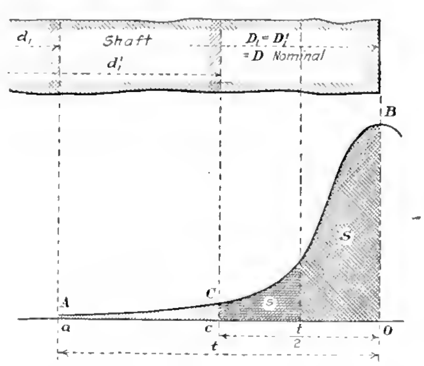

FIG. 21 GRAPHICAL REPRESENTATION OF THE REGIONS OF TOLERANCE WITH THE ASYMMETRICAL SYSTEM

diameter D, which may be easy to confuse with the maximum diameters D_1 and D'_1. The axis of symmetry of the curve

$$y = ke^{-h^2(x-D)^2}$$

is OY and the regions of tolerance are respectively defined by the ordinates Aa and BO for t and Cc and BO for $t/2$.

Here again the common part of the two regions of tolerance is represented by the shaded zone, but the area of this zone is equal to $s + S$ instead of $2S$.

If a regaging of the stock of shafts having the tolerance t be carried out and only those which have the tolerance $t/2$ be passed, the number of pieces to be kept will be represented by the cross-sectioned zone of area $2S$, where the symmetrical system of tolerances is in use, and by a zone of area $S + s$ in the case of the asymmetrical system, the difference in favor of the symmetrical system being represented by the difference between these two areas or by $S - s$. (Remarques sur le Système des Tolérances dans les Constructions Mécanique, A. C. *Le Génie Civil*, vol. 74, no. 11, May 3, 1919, pp. 353-355, 10 figs., *tp*)

MACHINE TOOLS, METAL-WORKING

CONTINUOUS MILLER. Description of a continuous milling tool designed by the Oesterlein Machine Co., Cincinnati, Ohio, which presents some novel features.

The body of the machine in general design resembles that of a punch press and is cast in one piece. It is claimed that the possibility of springing, due to working the machine to its maximum capacity, is avoided by the fact that the working surface of the platen and the cutter spindle are contained within the limits of the base casting.

The cutter can be held in a fixed position and the platen rotated continuously by means of an automatic feed, or the cutter may be reciprocated radially in combination with an intermittent motion of the table which is controlled by an indexing mechanism.

The spindle drive, Fig. 22, is taken from the driving pulley by means of miter gears to an intermediate shaft which connects with the first change-gear shaft in the speed box by means of a second pair of miter gears. The first and second change-gear shafts are connected by a single pair of change gears. The spindle speed is varied by means of pick-off gears on the two shafts.

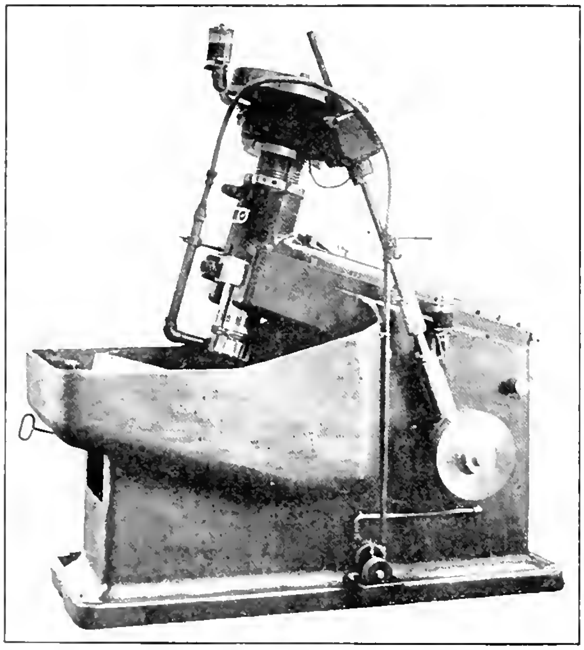

Fig. 22 Spindle-Drive Mechanism in the Oesterlein Continuous Miller

The spindle sleeve is provided with a vertical adjustment by means of a graduated collar which engages a coarse thread on the spindle sleeve. The spindle sleeve is clamped firmly in the split barrel of the ram after it is adjusted. The ram is fed radially over the surface of the platen by means of a cam which feeds the ram forward slowly during the cutting operation and permits it to drop back rapidly at the end of the stroke.

The relative travel of the ram is adjustable through the medium of a slide mounted under it. The slide is operated from the side of the ram by means of a bell-crank lever and is clamped with a knurled knob. The cam is driven by a worm and worm wheel in the feed box. A 4-gear feed-change mechanism regulates the platen feed when the continuous motion is in use. It also regulates the rate of speed of the cam when the indexing mechanism is employed. Thus the cutting feeds are established by the ratio of these change gears. The ratios are obtained by pick-off gears.

The rotary platen is set at a 15-deg. angle and is driven by a hardened worm and worm wheel. The worm is provided with ball thrust bearings and the box that carries the worm is gibbed to provide a means for compensating for the wear between the worm and worm wheel. (*Iron Trade Review*, vol. 64, no. 21, May 22, 1919, pp. 1359-1360, 3 figs. *d*)

MECHANICS

Application of Slope Deflection Method to Analysis of Statically Indeterminate Structures

Analysis of Statically Indeterminate Structures by the Slope Deflection Method, W. M. Wilson, F. E. Richart and Camillo Weiss. Frames composed of rectangular elements must in general be designed with stiff connections between the members at the joints, in order that loads may be carried. These connections must be capable of transferring not only direct axial tensile and compressive forces, but also bending moments. It follows that frames made up of rectangular elements are usually statically indeterminate; that is, the stresses in them can be found only by taking into account the relative stiffness and deformations of the various members. The common use of rectangular frames in engineering structures makes it highly desirable that the most convenient methods of analyzing their stresses should be developed. The stresses in a number of such rectangular frames have been analyzed by the writers and in their investigation they have made use of the so-called moment-area method given practically simultaneously in 1868 by O. Mohr in Germany and by C. E. Greene in lectures at the University of Michigan in this country.

The fundamental equations used in these investigations are expressed as follows:

1 When a member is subjected to flexure, the difference in the slope of the elastic curve between any two points is equal in magnitude to the area of the M/EI diagram for the portion of the member between the two points.

2 When a member is subjected to flexure, the distance of any point Q on the elastic curve, measured normal to initial position of member, from a tangent drawn to the elastic curve at any other point P is equal in magnitude to the first or statical moment of the area of the M/EI diagram between the two points, about the point Q.

The M/EI diagram is a graph in which the ordinate at any point is obtained by dividing the resisting moment, M, by the product of modulus of elasticity of material, E, and the moment of inertia of the section, I, at that point. If E and I are constant, the diagram will be similar in shape to the moment diagram for the member.

The fundamental equations are derived for moments at ends of members in flexure under various conditions of load and support, after which the writers proceed to the determination of stresses in statically indeterminate structures, to which by far the greater part of their discussion is devoted.

In this, two general methods of using the equations have been illustrated. In one case, after the equations have been written for each member of a frame by equating the sum of the moments at each joint to zero and employing one equation of statics, a number of equations are obtained which contain values of θ (angle between radii) and R $(= d/l)$ as the only unknowns. From these equations can be found the values of θ and R, which, when substituted in the original slope deflection equations, give values of the various moments. This method applies especially well to a frame in which a large number of members meet at each joint. Such a problem is generally best solved in numerical terms.

The procedure in the other case is more direct. The slope deflection equations for each member may be combined to eliminate values of θ and R, leaving equations involving the unknown moments, the properties of members and the given loading of the frame. These equations may be solved directly for the moments.

The following are some of the advantages of the slope deflection equations pointed out by the authors:

The general form of the fundamental equation is easily memorized, and the equations may be written for all members of a structure with little effort. The value of C or H for loaded members may be calculated by reference to two tables given by the writers. It is frequently possible to simplify the equations through noting where values of θ and R must be equal to zero from the conditions of the problem.

No integrations need be performed except possibly to find values of C and H, and there is little danger of the omission of

the effect of a single indeterminate quantity, as there is in methods involving the work of internal forces or moments.

The physical conception of a problem is easier than in the case where differentiation or integration is performed. When the slopes and deflections are determined, it is easy to visualize the approximate shape of the elastic curve of a member, whereas an expression involving the work of an indeterminate force or moment may have little physical meaning. Neither does the method of cutting a member and equating expressions for the linear and angular movement of the adjoining ends give so clear an idea of the actual deformation. To one unfamiliar with such a method the determination of the sign of the movement of the ends of the member cut is also more or less difficult.

Although the fact has not been brought out by the writers, these equations may be applied to many structures not composed of rectangular units. The determination of secondary stresses in bridge trusses is an example of such use which has been discussed in print for some time. With trapezoidal and triangular frames care must be taken in the use of the term R for adjoining members.

While the method is readily applicable to all the problems solved in this bulletin, its advantage over other methods is seen when applied to structures which are statically indeterminate to a high degree in which a number of members meet at each joint. (*University of Illinois Bulletin*, vol. 16, no. 10, Nov. 4, 1918, [Bulletin No. 108, Engineering Experiment Station], 214 pp., 112 figs., *tA*)

STEAM ENGINEERING

Is the Bucket Efficiency in Reaction Steam Turbines Materially Lower Than in Impulse Turbines?

Bucket Efficiency of Impulse and Reaction Steam Turbines, Prof. Tore G. E. Lindmark. First part of an extensive abstract of a paper in a Swedish periodical. In this paper the author claims that it is frequently stated that the bucket efficiency in a reaction steam turbine must necessarily be lower than the corresponding efficiency in an impulse steam turbine as long as the ratio between the peripheral velocity and heat drop for the reaction steam turbine does not exceed the most favorable values for the impulse steam turbine.

This means, in other words, that Σu^2, which is the sum of squares of peripheral velocities, must be greater in a reaction turbine than in an impulse turbine in order that, even apart from the influence of leakage losses, the former may attain the same degree of thermodynamic efficiency as the impulse turbine.

Professor Stodola, however, has shown that the reaction turbine with one-half degree of reaction has approximately the same ability for utilizing the relatively low peripheral velocities as an impulse turbine. The following considerations are presented by the author to combat the above expressed statement, which he considers to be incorrect.

The comparison between the efficiencies of impulse turbines and reaction turbines of various degrees of reaction is here limited by the author exclusively to the consideration of the bucket efficiencies, and by bucket efficiency is here understood the efficiency which relates only to losses in the guides and buckets, but not leakage losses, etc.

The author considers in this connection only one set of guides and buckets, and investigates the bucket efficiencies at various peripheral velocities in relation to a known heat drop. The so-called loss factor which originates in losses relating to thermodynamic efficiencies does not apply at all in this connection to the case of impulse turbines, since the investigation on this type of turbine has to do with but a single expansion. On the other hand, in the case of reaction turbine, even for a single guide and bucket set there is a certain loss factor, due to the fact that the steam expands not only in the guide, but also in the bucket. The losses in the first expansion raise the heat content of the steam, and therefore the expansion in the bucket starts from a somewhat higher heat content, and the heat drop in the bucket is somewhat increased thereby. At the same time this loss factor is so near unity that it can be neglected without creating thereby any very serious error.

If, for a start, all losses in the guides and buckets are neglected and the problem is simply considered as if the only loss were due to the absolute velocity of exit from the buckets, then the results obtained will be different from what has been indicated above. If it be assumed diagrammatically that all angles are equal to zero, then for the impulse turbine the following well-known formula will be obtained:

$$\eta_s = 1.0 \text{ if } u/c_0 = 0.5$$

where η_s = efficiency of bucket

u = peripheral velocity of bucket

c_0 = velocity of steam corresponding to the heat drop.

If the heat drop be denoted by W, then

$$A \times \frac{c_0^2}{2g} = W, \text{ where } A = \frac{1}{427}$$

In the case of a reaction turbine, 100 per cent bucket efficiency will not be obtained with the above indicated value of u/c_0. If the degree of reaction is, for example, 0.5, the heat drop will be divided into two equal parts between the guide and the bucket. Hence, the velocity of efflux of steam from the bucket will be

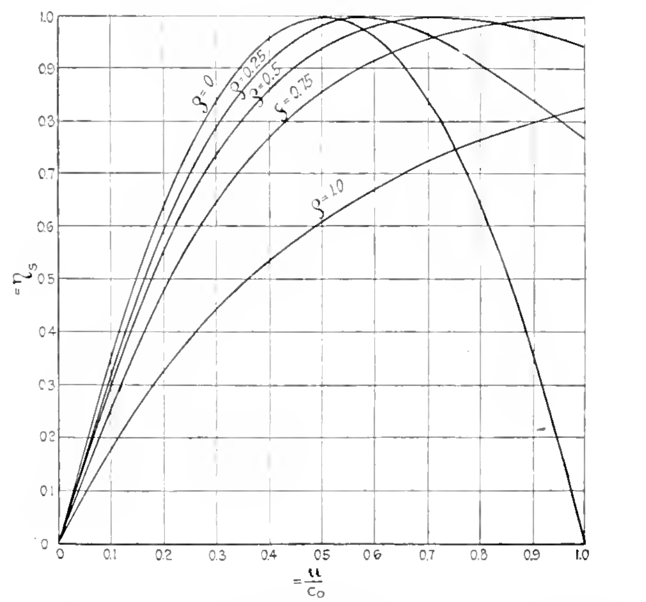

Fig. 23 Variation of Turbine Bucket Efficiency with the Peripheral Velocity for Various Degrees of Reaction

reduced to zero when the peripheral velocity is equal to the velocity of the steam, and therefore

$$\eta_s = 1.0, \text{ where } u/c_0 = \frac{1}{\sqrt{2}} = 0.708$$

If the degree of reaction lies between zero and 0.5, then $\eta_s = 1.0$ for u/c_0 having a magnitude between 0.5 and 0.708, and if the degree of reaction is greater than 0.5, then u/c_0 must have values greater than 0.708 in order that $\eta_s = 1.0$.

In the case of a complete reaction, the maximum bucket efficiency of unity is obtained only when $u/c_0 = \infty$.

It is of interest to see how the bucket efficiency under the above conditions varies with the peripheral velocity for various degrees of reaction.

Fig. 23 shows in the form of curves the variation of efficiencies with various u/c_0 values and five different degrees of reaction, viz., 0 (pure impulse turbine), 0.25, 0.50 (the usual so-called reaction turbine), 0.75 and 1.0 (pure reaction turbine). The curves illustrate the known fact that impulse turbines under the above conditions show greater ability for utilizing peripheral velocities than reaction turbines, and the situation with respect to the latter is the worse the greater the degree of reaction, and is at its worst for the pure reaction turbine. Nevertheless, it must be recognized that even under the above assumptions the difference of the bucket

efficiency between, for example, the pure impulse turbine and the reaction turbine with the degree of reaction = 0.5 is not excessively great. For example, with $u/c_0 = 0.4$ the reaction turbine operates with an efficiency only 10 per cent lower than an impulse turbine, and with $u/c_0 = 0.5$ with an efficiency only 6 per cent lower.

At the same time care must be taken not to draw from the foregoing considerations conclusions which are not justified by actual conditions. The curves mentioned have all been derived under the assumption that all the angles are equal to zero, and that there are no losses besides the absolute velocity of exit from the buckets, which is considered as being entirely lost. With the assumption of the presence of the usual angles the curves are somewhat displaced, although in the relative relations there are no material changes between the curves. Of more importance in this connection are the changes which are introduced by taking into consideration the losses in the guides and buckets due to friction, compression, etc., and also by considering the absolute velocity of exit from the buckets as not being entirely lost.

For a start the author continues to consider the absolute velocity of exit from the buckets as entirely lost, but introduces the usual angles in the guides and buckets, and takes into consideration the losses in flow through the guides and buckets. He uses the following notation in this connection:

A = amount of steam, kg. per hr.
c_0 = theoretical velocity of efflux of steam corresponding to the total adiabatic heat drop W for guide + bucket, meters per sec.
c_1 = actual velocity of efflux of steam from guides, meters per sec.
u = peripheral velocity of buckets, meters per sec.
ω_1 = relative inlet velocity of steam to bucket, meters per sec.
ω_2 = relative outflow velocity of steam from bucket, meters per sec.
c_2 = absolute outflow velocity of steam from bucket, meters per sec.
α = angle of guide
β_1 = entrance angle of bucket
β_2 = exit angle of bucket
φ = velocity coefficient for guides
ψ = velocity coefficient for buckets
N_s = actual bucket effect of velocity forces
N_t = theoretical bucket effect of velocity forces
$\eta_s = N_s/N_t$ = efficiency of bucket
ρ = degree of reaction

In all the calculations that follow it is assumed that β_1 is such that there is no shock at the velocity triangle in the inlet to the bucket.

For a pure impulse turbine, that is, one where $\rho = 0$, the following equations apply:

$$A \times \frac{c_0^2}{2g} = W$$

$$\text{hence } c_0 = \sqrt{\frac{1}{A} \times 2gW} = 91.5\sqrt{W}$$

$$c_1 = \varphi c_0$$
$$\omega_1^2 = c_1^2 + u^2 - 2\, c_1 u \cos \alpha$$
$$\omega_2 = \psi \times \omega_1$$
$$N_t = \frac{c_0^2}{2g} \times \frac{A}{3600 \times 75}$$
$$N_s = \frac{u \times A}{3600 \times 75 \times g} (\omega_1 \cos \beta_1 + \omega_2 \cos \beta_2)$$
$$\eta_s = \frac{2u}{c_0^2} (\omega_1 \cos \beta_1 + \omega_2 \cos \beta_2) \ldots\ldots\ldots\ldots [1]$$

When ϕ, ψ, α and β_2 are known, η_s can be calculated from Equation [1]. The author takes α = 18 deg. 10 min., and cos $\alpha = 0.95$; β_2 is taken to be equal to β_1.

For example, in turbines with guides, φ may with sufficient precision be taken to be equal to 0.95. It is more difficult to determine ψ. This coefficient appears naturally to be a function of the bending of the stream in the bucket and hence of the bucket angles β_1 and β_2. The greater $\beta_1 + \beta_2$ the less is the loss of velocity in the bucket and therefore the greater the magnitude of ψ. Professor Stodola tried to represent the function ψ/s of bucket angles in the form of a curve, but it is impossible to determine how far this curve approaches the actual conditions. It should, however, be borne in mind that the relative velocity when the stream bends in the bucket is not constant in all sections. Because of the difficulty of finding some satisfactory function determining the relations between ψ and $\beta_1 + \beta_2$ the author has assumed that ψ is not affected by the action of the angles and gives it a value 0.85, which is, roughly, a good value for multiple turbines of the

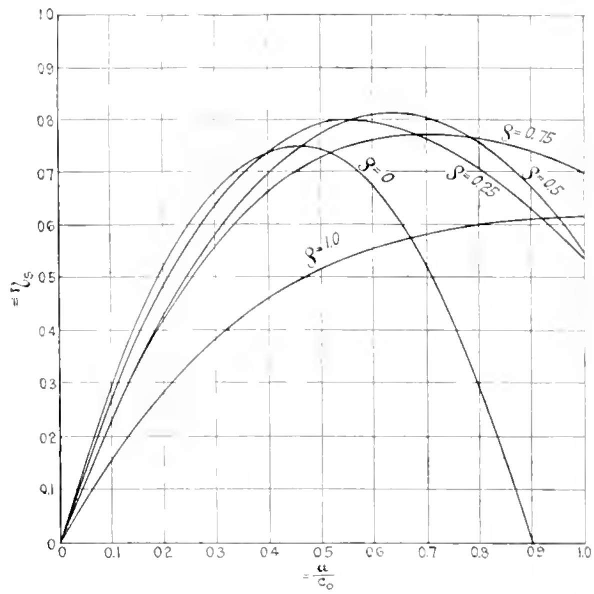

FIG. 24 VARIATION OF BUCKET EFFICIENCY OF PURE IMPULSE TURBINE WITH PERIPHERAL VELOCITY FOR VARIOUS DEGREES OF REACTION

impulse type with bucket angles of about 30 to 35 deg.

If the above numerical values be used the following equations are obtained:

$$c_1 = 0.95\, c_0 = 86.9\sqrt{W}$$
$$\omega_1^2 = c_1^2 + u^2 - 1.9 \times c_1 u$$
$$\omega_2 = 0.85\, \omega_1$$
$$\eta_s = \frac{2u}{c_0^2} \times 1.85\, \omega_1 \cos \beta_1$$

Since $\omega_1 \cos \beta_1 = c_1 \cos \alpha - u = 0.95\, c_1 - u = 0.9025\, c_0 - u$, we obtain

$$\eta_s = \frac{3.7u}{c_0^2}(0.9025\, c_0^2 - u) \ldots\ldots\ldots\ldots [2]$$

From Equation [2] are constructed the efficiency curves of Fig. 24 for the pure impulse turbine. From this the author proceeds to the consideration of combined impulse and reaction turbines with the degree of reaction ρ, which will be abstracted in the next issue. (Om Skevelverkningsgrader vid Aktions- och Reaktionsangturbiner, Professor Tore G. E. Lindmark, *Teknisk Tidskrift, Mekanik*, vol. 49, no. 24/3, March 12, 1919, pp. 37-41, 3 figs. *tA*, to be continued.)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

THE STILL ENGINE

Engineers who chanced to read the New York *Times* of May 28 had their curiosity aroused by a special cable dispatch from London under the heading, "New British Engine Surpasses the Diesel," giving a brief account of a paper read the previous day before the Royal Society of Arts on the Still engine, a combined internal-combustion and steam motor for which a thermal efficiency of 50 per cent was claimed. This paper, by Capt. F. E. D. Acland, was published in the *Journal of the Royal Society of Arts* of June 6, from which the following extracts and illustration, giving an idea of what it is claimed has been accomplished, have been taken.

The possibility of combining in one engine the superior thermal cycle at the high temperatures and pressures of the combustion engine with the low thermal cycle of steam to deal with its rejected heat, and in the same engine to add the superior working advantages of the steam engine, is the basis of work carried out by Mr. W. J. Still.

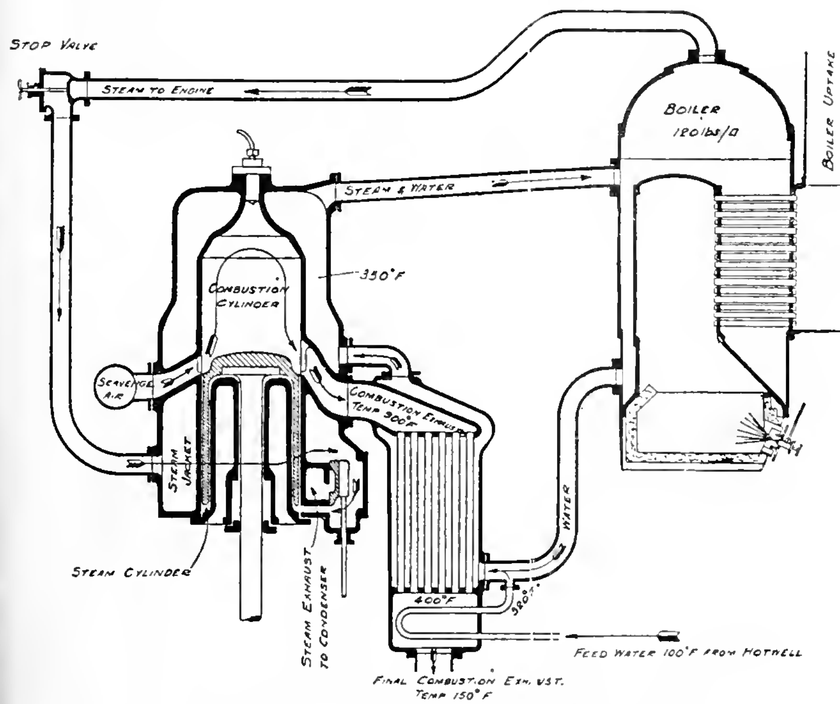

Diagram Showing Arrangement of Still Engine

The Still engine is an engine capable of using in its main working cylinder any form of liquid or gaseous fuel hitherto employed; it makes use of the recoverable heat which passes through the surfaces of the combustion cylinder, as well as into the exhaust gases, for the evaporation of steam, which steam is expanded in the combustion cylinder itself on one side of the main piston, the combustion stroke acting on the other side. It increases the power of the engine and reduces the consumption of the fuel per horsepower developed.

Its primary object is not to use the waste heat for raising steam, but first to use it in improving the thermal conditions of the working cylinder, and so insure the maximum efficiency from the fuel burnt within it, diminishing as a consequence the heat lost in that operation. Since the maximum efficiency is obtained by combustion of the fuel in the cylinder, and the minimum by the evaporation of the water in the steam generator, it is evident that the larger the quantity of steam which can be generated per horsepower developed by the combustion cycle, the lower must be the heat efficiency of the whole machine.

In the Still engine—see diagram—the jacket and cooling water form part of the circulating system of a steam generator, which may be an integral part of the engine, or external to it. The cooling water therefore enters and leaves the jacket at a constant temperature, regulated by the pressure of the steam, the cooling being effected by converting the water into steam without raising its temperature. Excluding the radiation losses, which are kept low by lagging, all the heat which passes through the walls is thus usefully recovered in the water as steam. The temperature of the cylinder wall is uniform over the whole of its exterior surface, and the heat lost to the cooling water at each stage of the cycle—compression, combustion and expansion—is diminished.

The exhaust gases after raising their quantum of steam are employed in preheating all the water required for the steam generated in the jacket water and the generator. Trials at full efficiency over long periods and steady loads show terminal stack temperatures as low as 150 deg. fahr.

The quantity of steam capable of being generated from "waste heat" depends on the efficiency of the combustion cycle and the load. Some years of experimental work prove that the weight of steam recovered may attain a maximum of about 7 lb. per b.hp-hr. developed by the combustion cycle of a four-stroke constant-volume engine at full load.

The first experimental engine constructed was a two-stroke engine capable of developing 500 b.hp. from three cylinders at 400 revolutions, bore 8 in. It was a high-speed engine, designed with special regard to obtaining data about the recovery of steam from waste heat (jacket and exhaust). It was first operated on town gas—540 B.t.u. per cu. ft., and subsequently converted for oil fuel. Its efficiency was not high, owing to its being a two-stroke engine with a short stroke, but its consumption per brake horsepower was 15 cu. ft. per hr. (31.3 per cent efficiency), a very promising result.

The outbreak of war prevented much progress being made in the design and construction of gas engines; but the results achieved give great promise of future development, for with a combustion indicated efficiency of 36 per cent, radiation 4 per cent, boiler loss 10 per cent, there remains 50 per cent for recovery; allowing 10 per cent efficiency for the steam cycle, a gain of 5 per cent is assured, and the total indicated efficiency of the engine will not be less than 41 per cent. If 20 per cent efficiency is obtained from the steam cycle, as appears possible, the total indicated efficiency will be 46 per cent.

A gas engine which can give a brake thermal efficiency 30 per cent better than its predecessors, and which, by governor control alone, can meet any demand up to and over 100 per cent overload, while maintaining a good efficiency at that increased output, cannot be neglected.

Four-stroke engines for petrol and similar fuels have been built and tested ashore and afloat. A special 13½ by 22-in. two-stroke-cycle heavy-oil engine with opposed pistons has been subjected to long and varied tests by representatives of various governments. The combustion takes place between the pistons, the steam acting on the return stroke at the back of both pistons. The best consumption of fuel—Admiralty shale oil—was as low as 0.302 lb. per b.hp. (scavenge pump not included) over a test of 1 hr. duration. This engine developed 330 b.hp. for 6 hr. at 360 r.p.m.—a single cylinder under waste-heat conditions. It will develop 400 b.hp. continuously with added steam—generated by fuel under the boiler—and has developed 540 b.hp. at 380 r.p.m. over short periods. (Combustion m.e.p., 128.2 lb.; steam m.e.p., 57.9 lb.; total m.e.p., 186.1 lb.) The thermal brake efficiency from below quarter load to full power is maintained at approximately 40 per cent over the whole range.

The application of the Still system to commercial marine work is being developed in this country and abroad, the two-stroke single-piston type, in powers of 100 hp. per cylinder and 400 hp. per cylinder, having been adopted. Engine of this type at 120 r.p.m., with a 22 by 36-in. cylinder, giving 4200 shaft hp. on two shafts, with all auxiliaries and water would approximate 600 tons. A geared turbine plant in a similar ship would weigh 20 per cent more and would consume approximately 2000 tons more fuel for a double journey lasting 1000 hours.

Bureau of Standards Publications

Circular 79, issued by the Bureau of Standards and prepared by G. W. Vinal and H. D. Holler, summarizes the available information on dry cells. A brief description is given of the materials and methods of construction, and an elementary theory of the operation of the cells. The various sizes and kinds of dry cells on the American market are described. The electrical characteristics of the cells and methods of testing them are discussed. In an appendix are given the proposed specifications for dry cells which have been prepared by the Bureau.

A second pamphlet, Technological Paper No. 109, gives practical suggestions for the conservation of tin in bearing metals, bronzes, and solders; much of the data having been obtained from questionnaires sent to representative manufacturers and users of these alloys. Tables are given showing the chemical composition and physical properties of many of the suggested alloys, and also for service tests of genuine babbitt and a high-lead bearing metal. Tentative recommendations for standard grades of bearing metal are also included.

The Detroit Meeting

The significant fact in connection with the Detroit meeting was the sustained interest in the professional and business sessions, from start to finish. The meeting opened on Monday, a day earlier than usual, and the business meeting was held on that day instead of the morning following, which virtually lengthened the period of the convention by one day. Nevertheless, a large number were on hand for business on Monday and stayed through the closing session on Thursday, which was one of the largest attended sessions of the meeting. The discussion at the various sessions was unprecedentedly large, that on Aims and Organization alone extending over a period of three days, and on Research for a full day. This number of Mechanical Engineering features reports of the Aims and Organization and the Industrial Relations sessions, while the August issue will report the Research and Pulverized Fuel sessions. In order to include the report, this number of Mechanical Engineering is issued one week later than usual, as announced on page 552 of the June number.

The Engineering Index

In this number of Mechanical Engineering an alphabetically-arranged index has been added to the items listed in the Engineering Index, in order to enhance its reference value.

When the Engineering Index was published by its former owners, the items were classified under the subject system. In taking over the Index, The American Society of Mechanical Engineers decided to retain the system of classification in order to test out the opinion of the membership as to its practicability. Experience has shown, however, that opinion is at least divided and that the alphabetical or dictionary arrangement of the items listed would be preferred by many members.

Because of the suggestions of the alphabetical arrangement which have come to us, it was decided to add the alphabetical index already mentioned until such time as a more decided preference can be expressed by our readers for the particular manner of arrangement for the Index items. The Editor of Mechanical Engineering will be glad to hear from members as to what they think is the relative desirability of the classified and alphabetical systems of listing items in the Index.

Report of the Nominating Committee

The following report has been received from the Nominating Committee appointed by President Cooley earlier in the year and which met at Detroit on June 16:

To the Secretary:

The Committee appointed by the President to nominate candidates to be balloted upon at the next annual election of the Society report a unanimous selection as follows:

For President:
Fred J. Miller, New York, N. Y.

For Vice-Presidents:
R. H. Fernald, Philadelphia, Pa.
E. C. Jones, San Francisco, Cal.
J. R. Allen, Pittsburgh, Pa.

For Managers:
D. S. Kimball, Ithaca, N. Y.
E. F. Scott, Atlanta, Ga. } Three-year term.
E. C. Fisher, Saginaw, Mich.
C. E. Lord, Chicago, Ill.: One-year term to complete term of Fred A. Geier—resigns December, 1919.

For Treasurer:
Wm. H. Wiley, New York, N. Y.

Respectfully submitted,
(signed) T. H. Hinchman,
John V. Martenis,
H. J. O. Hinchey,
Robert Sibley,
A. G. Christie,
Nominating Committee.

Detroit, June 17, 1919.

Anniversary Dinner for John A. Stevens

In celebration of the completion of a decade of successful business, an anniversary dinner was tendered to Mr. John A. Stevens, Engineer of Lowell, Mass., Vice-President of the A. S. M. E. and Chairman of its Boiler Code Committee, by his associate engineers and assistants at the Hotel Thorndike in Boston, Mass., on the evening of Saturday, May 17. About forty members of the organization were present and an informal reception was given to Mr. and Mrs. Stevens before the dinner.

The items on the menus, or "Fundamental Data" as they were called, were humorously couched in engineering terms, and the attractive front covers bore illustrations of one of the first plants built in 1909 and of a very large proposed super power house—recently designed in Mr. Stevens' office.

In the course of the evening the guest of honor was presented with a loving cup on behalf of the members of the organization, and received congratulatory letters and telegrams from many of his personal friends and clients. Mrs. Stevens was presented with a large bouquet of roses.

The associate engineers in Mr. Stevens' office are Messrs. Walter Slader, Clarence A. Bowen, Clarence Reeds, Francis Cunningham, Harry C. Lord, Carl J. Sittinger, George H. Thorpe and Marcus K. Bryan.

Services Acknowledged

At the request of the National Research Council, the Society, through its Standards and Technical Committee, has been privileged at various times during the past six months to furnish the French Government with information concerning American engineering and industrial standards. In all, nearly 200 publications have been transmitted (mostly in duplicate), embracing copies of engineering and safety standards and codes of the various engineering societies, publications of the American Pharmaceutical Association, chemical, mining and mechanical equip-

ment catalogs, and specifications and working drawings of United States standard locomotives and rolling stock. That the material thus collected and sent has been helpful, is evidenced by the letter reproduced below, which was recently received by the Society.

Office of the Scientific Attache to the American Embassy,
4, Place D'Iena

Paris, May 26, 1919

The American Society of Mechanical Engineers,
New York, N. Y.

Gentlemen:

The material collected by you for the French Government on the United States engineering and industrial standards has been received and transmitted to the services interested.

I wish to take this opportunity of thanking you in behalf of the French Ministry for the very comprehensive and valuable mass of material which you have assembled and put into convenient form for use. It will certainly be of great value here where standardization in the industries is in a very rudimentary state and where an organized attempt is now being made to introduce order into the engineering practice.

Very truly yours,
(Signed) H. M. Howe,
Scientific Attaché.

Honor for George Ellery Hale

George Ellery Hale, Director of the Mount Wilson Observatory and Foreign Secretary of the National Academy of Sciences, who has been for the last ten years a Correspondent of the Académie des Sciences, Institut de France, has received the unusual honor of election as Associé Étranger, taking the place of Adolph von Baeyer, declared vacant by the Academy. The Foreign Associates are limited to twelve, and the high distinction has been held by only two Americans—Simon Newcomb and Alexander Agassiz.

The National Research Council, upon the presentation and acceptance of Dr. Hale's resignation as its chairman and the election of James R. Angell as his successor, created and bestowed in perpetuity upon Dr. Hale the title of Honorary Chairman in recognition of his services to the National Research Council and to science and research by indefatigable efforts that have contributed so largely to the organization of science for the assistance of the Government during the war, and the augmentation of the resources of the United States through the newly intensive cultivation of research in the reconstruction and peace periods that are to follow.

Cleveland Engineering Society Honors A.S.M.E. Members

The Cleveland Engineering Society at its annual meeting on June 10 conferred Honorary Membership upon Dr. Charles F. Brush, Member A. S. M. E., and Worcester R. Warner, Past-President A. S. M. E. Dr. Brush was honored because of the important contributions he has made to the field of electrical engineering. He was the inventor of the arc lamp and many electrical devices.

Mr. Warner's connection with the machine-tool industry and his contributions to the science of astronomy are well known. In collaboration with Mr. Ambrose Swasey, his work represents the most notable development in the design and construction of telescopes and other instruments of precision for astronomical observation. The three great refracting telescopes, including the 36-in. Lick, the 40-in. Yerkes, and the 26-in. U. S. Naval, were all the products of his firm.

Summer School of Industrial Management

The fourth summer session in factory organization, cost accounting, employment and scientific management will be held at Pennsylvania State College, State College, Pa., August 11 to 23.

The mornings will be devoted to lectures and discussions on organization, cost accounting and employment management and will be conducted by Major Hugo Diemer, Mem. Am. Soc. M. E., formerly professor of industrial engineering at the college and now superintendent of personnel, Winchester Repeating Arms Co. During the war Major Diemer served in the Ordnance Department, where he was in charge of important munitions work at the U. S. Cartridge Co. and the Bethlehem Steel Co.

The afternoon practice work in making time and motion studies, routing, scheduling, etc., will be in charge of Lieut. J. C. Keller, Jun. Am. Soc. M. E., Major Diemer's first assistant in industrial engineering instruction at the college. A fee of $25 is charged for the course and equipment is available for a class of 30 students.

Labor and Scientific Research

Mention was made in the June number of Mechanical Engineering (page 558), of the organization of scientific and technical employees of the Government as a branch of the National Federation of Federal Employees, which is affiliated with the American Federation of Labor. Immediate cause for this movement was the action of the Joint Congressional Commission on Reclassification of Salaries of Federal Employees, this Commission preferring to deal with organizations rather than with independent groups. It is noteworthy that one of the first accomplishments of the new organization has been the securing of the adoption by the American Federation of Labor at its Atlantic City meeting of resolutions favoring scientific research as the basis for increased productivity in the industries and the promotion of the health and well-being of the employees—a recognition of fundamental principles, which, until recently, labor has seldom been willing to accept. The resolutions were introduced at the convention jointly by the National Federation of Federal Employees and by the American Federation of Teachers. The most important clauses embodied are given below:

The American Federation of Labor adopted the following resolution at its Atlantic City convention:

Whereas, Scientific research and the technical application of results of research form a fundamental basis upon which the development of our industries, manufacturing, agriculture, mining, and others, must rest; and

Whereas, The productivity of industry is greatly increased by the techincal application of the results of scientific research in physics, chemistry, biology, and geology, in engineering and agriculture, and in the related sciences; and the health and well-being not only of the workers but of the whole population as well, are dependent upon advances in medicine and sanitation; so that the value of scientific advancement to the welfare of the nation is many times greater than the cost of the necessary research; and

Whereas, The increased productivity of industry resulting from scientific research is a most potent factor in the ever-increasing struggle of the workers to raise their standards of living; and the importance of this factor must steadily increase since there is a limit beyond which the average standard of living of the whole population cannot progress by the usual methods of re-adjustment, which limit can only be raised by research and the utilization of the results of research in industry:

Resolved, By the American Federation of Labor in convention assembled, that a broad program of scientific and technical research is of major importance to the national welfare and should be fostered in every way by the Federal Government, and that the activities of the Government itself in such research should be adequately and generously supported in order that the work may be greatly strengthened and extended.

American Drop Forge Association

Progress in the establishment of standards for forgings was reported at the sixth annual convention of the American Drop Forge Association held at Pittsburgh, June 12-14, by the committee on standardization, which since the signing of the armistice has investigated the allowable limits for automobile crankshafts, gears, camshafts, connecting rods and axles. In his presidential address, E. J. Frost, Jackson, Mich., laid stress on this subject of standardization which, he observed, affords the greatest opportunity for eliminating waste and improving undesirable conditions.

W. O. Renkin, New York, read an interesting paper on Development in the Use of Powdered Coal in the Forging Industry, in which he claimed that the principal requirement of a furnace to burn powdered coal successfully is a relatively large combustion chamber of proper design. By proper design he

meant one which allowed the particles of coal to combine properly with the correct amount of air and burn at a minimum pressure above precipitation.

Earl E. Adams, Dayton, Ohio, spoke on Producer Gas as a Forge-Shop Fuel, and said that the gas must be cold to reduce the moisture and clean to prevent the clogging of the mains. He referred to a glass-wool tar extractor said to have an efficiency of from 99.95 to 99.98 per cent and made up of a mat of glass wool or spun-glass thread. A 20-in. mat, capable of handling 20,000 cu. ft. of gas an hour, contains 300 miles of this spun-glass thread. When made into a mat it is equivalent to 250 plies of 90-mesh screen.

Other technical topics were: Forge-Shop Profits, by F. A. Ingalls, Harvey, Ill.; Sand Blasting Versus Pickling, by R. R. Shuman, Chicago; Die Cost as a Factor in Selling Forgings, by R. T. Herdgen, Walkerville, Ont.; Heat-Treating Problems That Originate in the Forge Shop, by W. C. Peterson, Detroit, Mich., and Fusion Welding as Applied to Drop Forgings, by S. W. Miller, Rochester, N. Y.

A Word from Roberts College

The A.S.M.E. headquarters was recently favored by a call from Prof. Lynn A. Scipio, Mem.Am.Soc.M.E., Director of Engineering of Roberts College, Constantinople. Plans are under way for the expansion of the engineering school, and Professor Scipio is here to recruit a teaching staff.

Some one has said that the only good thing that has happened in Turkey is Roberts College; and certain it is that it has been the most potent civilizing and educational influence in that country and throughout the Balkan states.

In this work the engineering school is assuming an important place. The original plans for the school were made by Prof. John R. Allen, Mem.Am.Soc.M.E., in 1911 and 1912. He was followed by Professor Scipio, who went from the University of Nebraska to develop the school. Three courses have been offered in Civil, Mechanical and Electrical Engineering, and a course in Mining is contemplated. A shop building with limited equipment has been erected and a power plant at a cost of $100,000.

The college was able to remain open during the war, although its courses were curtailed. When diplomatic relations were broken off with Turkey, the United States Government ordered its citizens out of the country. A few remained at the college, however, and carried the work with the aid of native instructors. Frequent attempts were made both by the Germans and Turks to confiscate the buildings for other purposes, but these were thwarted through the diplomacy of the college president, Dr. C. F. Gates. The Germans dominated the situation and were in every office, and finally attempted to starve out the college by making flour contraband on the ground that it was needed by the army. The engineering department then proceeded to build a flour mill, which was successful in tiding over the situation.

Coal was bought for the power plant at $80 and $100 a ton, although much of it consisted only of earth scrapings from the bottoms of former coal piles, and was worthless. Money for the continuance of the college was secured mainly through personal contributions by Greeks and Armenians. Notes were sold at 2 per cent interest, which were readily disposed of, as it was felt that the college was sound and would be well supported financially, and many natives believed it provided a safer investment for their money than any other institution.

16 Hours, 12 Minutes

Since the NC-1 of the United States Navy has shown the way across the shorter part of the Atlantic there have been several highly significant developments.

The Sopwith biplane with Hawker and Grieve started from Newfoundland, but was not able to complete the crossing owing, as has been stated, to minor troubles in the water-circulation system of the engine. The plane had to land on the water after a flight of little in excess of 1000 miles, but the pilot and navigator were saved by a passing steamer.

Another attempt on Sunday, June 15, made by Capt. John Alcock and Lieut. Arthur W. Brown, British officers, in a Vimy biplane was successful and the two fliers crossed the Atlantic from Newfoundland to Clifden, Ireland, in 16 hours and 12 minutes.

The events of the last four weeks taken in their entirety point to several significant facts. In the first place, altogether five machines made this attempt—three in the shorter southern direction and two in the longer northern direction, and only two of the five have reached their goals, the other three landing on the water. Nevertheless, not a soul was lost in these flights, and even the dare-devil attempt of Hawker and Grieve has ended with all hands safe. This would indicate essentially that flying over an ocean upon which so many vessels are constantly plying as on the Atlantic along its trade routes is probably less dangerous than would appear at first sight.

The second lesson brought out by the flight of Alcock and Brown lies in the fact that they had to cross the ocean under unusually trying conditions, and succeeded in doing so, nevertheless. It would appear from this that even in the present state of long-distance aerial transportation a flight 1900 miles is practically achievable, and if the tremendous strides made in aerial navigation in the last years be considered, it will become fairly obvious that ere long the establishment of regular aerial transportation across the ocean may be expected.

It may well be pointed out here that these transoceanic flights represent really the first obviously important commercial application of aircraft. At present and for the first few years to come, there is no question but that air transportation will be considerably more expensive than all other existing means of transportation, not only because it necessitates the use of a heavier fuel but also because the depreciation of the machinery used per pound of weight carried is greater than in the case of motor trucks, railway trains, or steamboats.

The only point where air transportation is unquestionably superior to any other form of transportation is in its speed, but even in land transportation the superiority of aircraft speed is not great enough in a good many cases to compensate for its higher cost. Thus, taking such two points as New York and Chicago, air communication would only in comparatively few cases be fast enough to save even one business day between these cities.

The situation, however, is entirely different with transatlantic transportation. While there are one or two boats that can make the passage in five days and some hours, the average time from Liverpool to New York is between six and eight days, which means that all fast transportation of messages must depend upon the cables and wireless. With a 24-hour schedule between London and New York it would be perfectly possible to receive London papers in time for abstracting them in New York papers of the next day, while letters between London and New York would be delivered as promptly as they now can be between New York and Chicago.

In banking, important business transactions and especially in engineering enterprises the ability to send a draft or a blueprint from New York to London or back in 24 hours will not only be a great help to the growing American export trade but will also create an important source of business for the aerial navies of the near future.

Edwin J. Prindle, A. S. M. E. representative on the Patent Committee of the National Research Council and who presented a paper at the January 14 meeting of the New York Section dealing with the movement to increase the efficiency of the Patent Office and the patent system (see Mechanical Engineering, February 1919, p. 147), has just been appointed Chairman of the Patent and Related Legislation Committee of the American Chemical Society.

At the recent convention of the National Association of Manufacturers, addressed by Mr. Prindle on the subject, a resolution was passed approving the report of the Patent Committee of the National Research Council to that body and the enactment of its legislative program.

THE DIVISION OF ENGINEERING OF THE NATIONAL RESEARCH COUNCIL

At the Research Session of the Spring Meeting of the A. S. M. E., an address was given by Mr. Galen H. Clevenger, Acting Chairman of the Division of Engineering of the National Research Council, on the organization and work of the Council and of the Division of Engineering with which he is directly connected, at present in charge of the headquarters of the Division of Engineering in the Engineering Societies Building, New York.

Mr. Clevenger reviewed the organization of the National Academy of Sciences which came into being during the Civil War through the action of President Lincoln; and of the National Research Council which similarly was organized during the present war at the request of President Wilson. Lately, the National Research Council has been reorganized on a permanent basis for promoting research among the industries of the country.[1]

In his address Mr. Clevenger also reviewed the war organization and work of the Division of Engineering, followed by an account of the present activities and affiliations of the Division of Engineering, from which the following is taken:

War Organization of Division of Engineering

The Division of Engineering comprised four sections: A section on Metallurgy, a section on Mechanical Engineering, a section on Electrical Engineering and a section on Prime Movers. The work of each section was under a chairman, who was directly responsible to the chairman of the division.

The Section on Metallurgy had for its principal work the solving of metallurgical problems arising in connection with the conduct of the war, more particularly those brought to it by the military. This work was accomplished through the medium of committees, whose personnel included leading authorities upon metallurgy.

The Section on Mechanical Engineering established a drafting room in charge of a chief draftsman, at Research Council headquarters and through the generosity of the Carnegie Institute of Technology a machine shop at Pittsburgh under the direction of a foreman. These were used for the development of inventions referred to the Section by the Divisions of Engineering and Physics.

The Section on Electrical Engineering concentrated its efforts upon the problem of electric welding, more especially electric welding as applied to ship building. This section worked in very close coöperation with the Emergency Fleet Corporation, who financed its investigative work.

The Section on Prime Movers devoted its attention chiefly to the design and development of power plants for aircraft.

The efforts of each section were so directed as to be of the greatest service in the solving of the problems of greatest immediate need to winning the war; each has to its credit important achievements during the war period. (See Report of the Academy of Sciences for the Year 1918.)

Present Organization and Affiliations

The purpose of the National Research Council is to promote research in the mathematical, physical, and biological sciences, and in the application of these sciences to engineering, agriculture, medicine, and other useful arts, with the object of increasing knowledge, of strengthening the national defense, and of contributing in other ways to the public welfare. Affiliation with similar organizations abroad is rapidly bringing about an International Research Council.

The Division of Engineering consists of three representatives of each of the four founder engineering societies, the societies so represented being the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers. Further, there is one representative each from the four more important non-founder societies, the societies so represented being the American Society for Testing Materials, the American Society of Illuminating Engineers, the Western Society of Engineers, and the Society of Automotive Engineers. In addition to the representatives of the engineering societies there are 12 members at large, making a total membership in the division of 28. Eight members of the division are also members of Engineering Foundation.

The Engineering Foundation has from the beginning taken a very active and important part in furthering the work of the whole council; indeed in the earlier stages of the war organization, when the funds available for carrying on its work were very limited, Engineering Foundation gave the services of its secretary and substantially its whole income to the support of the Council, this arrangement continuing until support was secured from other sources.

Recently a plan of close affiliation of the Engineering Foundation and the Division of Engineering has been approved by the members of the Engineering Foundation and the Division of Engineering, and also by the Executive Board of the Council. In compliance with the terms of this agreement the Engineering Foundation has provided the Division of Engineering with an office in the Engineering Societies Building, New York, together with necessary clerical assistance. It further has agreed to make appropriations of its funds to aid specific undertakings of the division from time to time as may be later determined; and in fact at the present time an arrangement has been practically effected whereby the Engineering Foundation undertakes the financial support of the work of the Committee on Fatigue Phenomena in Metals.

The location of the Engineering Division in the same building with the headquarters of the national engineering societies and its close affiliation with the Engineering Foundation renders it a very potent factor in promoting engineering research.

The Engineering Division is not to be regarded as an instrument of research, but rather a stimulator and coördinator of research. It is not the master but the servant, eager to aid in the bringing together of research agencies and uniting them in larger projects of research than would be possible through individual effort. Its principal object is to get more and better research done in engineering, carefully avoiding the position of being a dictator, or of assuming credit for work which it has encouraged others to do.

The Engineering Division is at present carrying on its work largely through the medium of committees. Much thought has been devoted to developing a plan of organization of research committees which will render them most effective. It is clearly recognized that within every committee there should be an active group which is in a position to do the actual work of research. A chairman is provided who is thoroughly familiar with the subject in hand and who has sufficient time to devote to the work; furthermore, financial support necessary to carry on the work is provided so far as possible. When all of these conditions are provided for, effective work may be expected from the committee, even though the larger group of the committee may be busy men who can do little more than act in an advisory capacity.

The Engineering Division now has some 14 committees working upon a variety of subjects. These are in various stages of organization.

Every effort is being made to take up researches of broad general interest. At present 21 states, extending from the Atlantic to the Pacific, are represented on these committees and the number is rapidly increasing.

[1] For further references to the history and organization of the National Research Council see pamphlet copy of Mr. Clevenger's address; also the following references to Mechanical Engineering: May, 1919, p. 485; June, p. 559; and the present issue, p. 592.

ENGINEERING COUNCIL

Engineering Council[1] is an Organization of National Technical Societies of America, Created to Consider Matters of Common Concern to Engineers, as Well as Those of Public Welfare in Which the Profession is Interested

Classification and Compensation of Engineers

THE Committee on Classification and Compensation of Engineers, whose personnel was given in the May issue of MECHANICAL ENGINEERING (p. 488), is now actively engaged in securing data upon which to base its final report. This committee is divided into three sections, Federal, Railroad, and Municipal and State. Preliminary reports were recently rendered by each and in submitting them to Engineering Council the Committee outlined its method of procedure in attempting to formulate standard rates of compensation for professional engineers. The first task is to find what rates are actually in force, especially in those fields where attempts at standardization have been made, and the second is to inquire what adjustment should be made to correspond to the great change which has taken place in the cost of living. How great this change has been during the past 20 years is realized by few. Fortunately an accurate determination is available in the statistical records of average prices which for many years have been gathered and published by leading commercial organizations. A record of average prices of the necessaries of life kept by R. G. Dun & Co., shows that prices have increased continuously for 22 years. A certain quantity of staple necessaries which could have been purchased July 1, 1897, for $72.45, by January 1, 1905, cost $100.32. On January 1, 1914, before the outbreak of the war, the cost had risen to $124.53; May 1, 1917, to $208.43, and October 1, 1918, to the maximum of $233.23. This enormous increase in prices of the necessaries of life has been accompanied by an increase in wages, among workers organized in unions which had the power to compel attention to their demands, but no such increase has taken place in the compensation of salaried workers in the professions. It has been assumed that these workers, living in a different social environment, had a margin of compensation sufficient to enable them to meet the increased cost of living. This assumption, however, is not justified by the facts. Where salaries have been increased during the past three years, there are few cases in which the increase has been at all commensurate with the increase in prices of the necessaries of life, which the salaried worker, like the wage worker, has had to purchase.

There has been a general belief that with the coming of peace and the resumption of productive industries, a heavy fall in prices would occur. It has been assumed that the salaried worker would have to wait for this so that he could again live within his income. It now appears, however, to be the opinion of many financiers and economists that the present high prices of necessaries are likely to continue for a long time, probably for several years. If this is so, then surely the salaried worker, in a professional or any other occupation, has an equitable claim to have his compensation brought back in purchasing power to where it was fifteen years ago.

There is another aspect of the compensation of the professional worker which has been frequently misunderstood, but which with present knowledge ought no longer to deceive. The pay of professional engineers has for many years been influenced by the idea that a young man in the earlier years of his work should expect moderate compensation because of the future to which he might look forward. There was justification for this idea during the period when the development of engineering was so rapid that a large proportion of the men who were turned out from the few engineering schools or the engineering workshops were able eventually to rise to positions of large responsibility and importance, commanding high salaries. That condition has now been altered. Of the men who begin technical engineering work today, only a very few selected ones can rise to positions of responsibility commanding high salaries. The man of exceptional ability, indeed, may find it worth his while to work for low compensation because of the future awaiting him. But to hold up to the rank and file of technical workers the idea that they can afford to work for insufficient salaries for the sake of some future high position, is a gross deception.

The Committee believes, therefore, that in adopting standards for the compensation of workers in all technical fields due consideration should be given to the great increase in the cost of living. The dollar of salary must be considered with regard to what it will purchase today and is likely to purchase next year, and not with regard to the value of the dollar ten or fifteen years ago. This increase in compensation is necessary not merely as a matter of justice to the engineer, but in order that engineering work may be maintained on the plane that it must be to secure economical and efficient work. There is no economy in paying such men at rates inadequate for their support, for this leaves their minds burdened with anxieties, when they should be free to give their best efforts to the work in hand. Moreover, such a rate automatically tends to drive the abler men into other occupations and to leave in charge of the work only those of less ability. The Committee has therefore recommended that it be directed to formulate a definite classification for each of the services under consideration and a schedule of compensation which might reasonably be fixed for positions in each class.

Federal Government Section. A survey of Government activities shows that there are twenty-eight offices that employ Government engineers. A letter was sent to each departmental secretary outlining the work of the Committee and requesting assistance in furnishing a list of engineering bureaus in his department and in issuing instructions to the chiefs to furnish the needed data. Favorable responses from all departments were received, except the War Department, which stated it would be impracticable to furnish the information desired. But little work has been done, however, as an analysis of the data collected cannot be made until the majority of the reports have been received.

Railroad Section. The chairman of this section prepared a questionnaire to be sent to the chief engineers of the railroads under Federal control on the supposition that the salaries of all the men in the various departments of the Railroad Administration were a matter of public knowledge, and also requested recommendations on an unofficial basis from them. Before sending out this questionnaire, however, the chairman made a personal call on Director-General Hines and discussed with him the propriety of making such a request. Mr. Hines did not think that the matter should be approached in the manner suggested, nor that the employer should be called upon to furnish a list of salaries and to express in advance an opinion as to how these salaries should be changed; but did state that he did not see any objection to our getting the information from members of the Founder Societies. The chairman acquiesced in Mr. Hines' views, and has accordingly confined his questions to members of the Founder Societies.

Municipal and State Section. By reason of the wide variety of titles used for the municipal and state service, the Committee found it necessary to undertake the formulation of a standard classification of positions and duties, before attempting to investigate the question of compensation. The assistance of the Municipal Engineers of The City of New York was invoked in this particular, and after a painstaking investigation by a representative committee a schedule of suitable titles with corresponding qualifications and duties has been prepared. The fitness of this schedule for general use is now under consideration by the Committee. As soon as an agreement shall have been reached, it is proposed to incorporate it in a questionnaire for circulation among the engineers of all states and the more important cities with a view to determining present compensation and changes which should be made. It is hoped that the classification finally agreed upon will prove broad enough to cover all municipal and state engineering service, and that it will be accepted as a substitute for the variety of standards now in use.

[1] Officers of Engineering Council: J. Parke Channing, *Chairman;* Alfred D. Flinn, *Secretary,* Engineering Societies Building, 29 West 39th Street, New York.

NATIONAL SERVICE COMMITTEE

Contributed by the Washington Office [1]

National Department of Public Works

The proceedings of the conference held at Chicago, April 23 to 25, to consider the formation of a Department of Public Works were published in the June issue of Mechanical Engineering, p. 557. Since then the work in general has been divided into four parts:

Organization of Executive and Finance Committees
Drafting of a bill
Organization of a Campaign Committee
Review of public-works laws of other countries.

The Committee on Text of Bill has completed its labors. After approval by the Executive Committee it is the intention to consult leaders in Congress and secure advice as to its introduction. After it is introduced and has thereby gained official status, copies will be freely distributed among the various federated organizations. Suggestions concerning amendments will then be solicited.

The review and compilation of public-works laws of other countries is also practically completed, covering all the larger powers, three British dominions, four South American republics, and several small European kingdoms.

The organization of the Campaign Committee has been a huge task and is by no means completed. It was apparent at the outset that a committee would be required consisting of one or more members from each state in the Union. It is impossible to make such a committee function as a unit and therefore it was determined, subject to approval of the Executive Committee, to create separate state committees, all synchronizing with the Washington office. Campaign conditions vary widely in the several states and residents in each state are better qualified to determine details of campaign than any general committee. The Chairman has written several hundred original letters to men in the several states urging them to undertake the campaign work. Many replies, both favorable and unfavorable have been received, but from the majority of the states no responses have been returned. Formation of committees is now under way in New England, New York, Ohio, Michigan, Wisconsin, Minnesota, Illinois, Kentucky, Missouri, Kansas, West Virginia, Georgia, Florida, Louisiana, Texas, Nebraska, North Dakota, Arizona, California, Washington, Oregon, and Idaho.

It seems wise in the conduct of this campaign to avoid the outworn and objectionable methods that have been followed by practically everyone during the past generation. The very character of the project and the standing of those participating in it demand that the campaign shall be conducted on a high and dignified plane. It should be the duty of the several state camapign committees to select in each congressional district men qualified to give advice along such lines. The Washington office should supply the particular facts, instances and arguments that are apparent to everyone on detailed study, but which may or may not be familiar to those who approve the project on general principles.

It is not expected that a campaign of any kind can be immediately successful, but it is believed that the open and aboveboard procedure here outlined, steadily and progressively maintained, will result in the making of fast friends in official circles and in bringing a successful conclusion sooner and with less acrimony than any other method now apparent.

Relations with Congress

In order to introduce Engineering Council to members of Congress and to make known its purposes, the following letter has been addressed to the chairman of twenty-eight committees of the House and Senate. Appreciative acknowledgments have been received from a large number of them.

This is addressed to you on behalf of Engineering Council for the purpose of informing you concerning its aims and purposes, and of ways in which it may be useful to you in your official capacity.

Engineering Council is the central organization, made up of representatives appointed by the various national societies and institutions of engineers, including the American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers, American Institute of Electrical Engineers and American Society for Testing Materials. These national societies have focused their common aims and affiliations in Engineering Council, and said Council represents the highest type of engineering thought and experience in the United States.

One of the chief aims of the Council is that of national service. It proposes to lend its services to the Government when so invited, and to give counsel and advice on engineering matters. By this announcement it is desired to inform you that, if in your official capacity, you wish to secure the unprejudiced assistance of a body which comprises within its membership and affiliations the best qualified engineering authorities of the country, you have merely to make your desires known and Engineering Council will place at your disposal a group of men which will merit your entire confidence. Such service will naturally have to be confined to counsel and advice as to policies and plans.

It is hardly necessary to add that no compensation will be asked or expected for such service, the aim of Engineering Council being to give its services to the country and thereby contribute its appropriate part to the general well-being.

Government Contracts

The National Service Committee has placed before Engineering Council the matter of a uniform type of construction contract for use by Government agencies. At present there is a heterogeneous mixture of many kinds of contracts, from the old-fashioned lump-sum bid to the more complicated, so-called "cost-plus" contract. There is much discussion going on concerning these types of contract and many members of Congress are persuaded that either the one or the other kind is fundamentally wrong. It will be recalled that during the war a modified form of cost-plus contract was used by the Construction Division of the Army, which form was absolutely essential to the emergency work that was required. This form of contract has engendered much opposition and yet there are persons who advocate that it be adopted throughout all Government construction procedure whether in war or in peace. It is a subject quite unfamiliar to the legislator who has not given much study to it and there is always the danger that by riders to appropriation bills which go through in a hurry and without mature consideration, the construction work of the Government may be seriously hampered as it already has been in some instances in the Construction Division. Long before the war, there was need for reform, especially in the river and harbor work and that of the Reclamation Service. Under the lump sum process in vogue too many contractors failed, with the result that great losses were involved, not only on the part of the contractors, but also on the part of the Government. This subject, with especial reference to the cost-plus contract, has already been studied officially by one member of Council, who as chairman of a committee, during the early part of the war, rendered a report in favor of the cost-plus principle followed by the Construction Division. This is unquestionably a matter of great importance, and should receive thorough consideration by a qualified committee, and ultimately be made a subject of legislation.

Relations of Engineering Council to National, State and Local Societies

At the last session of the Chicago Conference, the chairman announced an opportunity for frank discussion of society relations which it was hoped would bring all engineers into harmony. The chairman of Engineering Council gave facts concerning Council and the methods and limitations under which engineering societies could become members. The discussion which followed gave clear indication that it was the desire of the delegates that some closer relation should be achieved. The remarks of W. H. Hoyt, delegate from the Minnesota Joint Engineering Board, conveyed the sentiments of those present as well as those of many others:

Engineering Council has done wonderful work in the few years it has been organized. They have shown to my mind simply the pos-

[1] Washington Office in charge of M. O. Leighton, *Chairman*, National Service Committee, McLachlen Building, 10th and G Streets.

sibilities. They have merely opened up the field. The appointment of their committees alone shows the enormous work that is to be done and can be done, but I believe, gentlemen, that it will not be a success until that Council is organized in some way so that it may feel the effect directly from the individual member at home, just exactly in the same way that your representative sits up and takes notice when he gets a letter from home—that represents personal and local interest. How that can be brought about, I don't know. It will be developed; there is no question about that. The men that are at the head of this question now are men capable of producing those results, and I can see it coming. As Mr. Channing has said, the question now is a live one. In my opinion, Council cannot be a success until it has a broader form of government, more personal backing and support from the individual societies throughout the country which give it its life and also the general support and backing which it will be able to obtain when they have such control over such an organization. In regard to financial backing, I believe there will be no question at all of obtaining all the finances necessary if it has the organization, shows the disposition and has the direct and immediate initiative to take hold of that work and the will to do it.

The National Budget

A national budget system, which engineers have long regarded as essential to the proper conduct of our fiscal affairs, is at last being seriously considered by Congress and seems likely to be adopted in some form. Several bills and joint resolutions have already been introduced but the measure which seems to attract the most attention is that introduced by Representative Good, Chairman of the House Committee on Appropriations. The origin of the bill is not without its significance because some of the strongest opposition to a budget system that has heretofore been developed in Congress has come from the members of this important committee.

The Good bill provides for the creation of a Bureau of the Budget in the office of the President, to which full information shall be furnished by all Departments and other Governmental agencies concerning powers, duties, financial transactions, business methods, etc. This Bureau is authorized to make investigation of all provisions of law dealing in any way with the preparation and transmission to Congress of estimates and other financial data, in order to determine what changes should be made, to the end that all the requirements shall be brought in harmony with an alternative budget which the President is authorized to submit to Congress. The President is further authorized to submit his recommendations as to how the needs of the Government should be met, and such further data regarding the financial affairs of the Government as he deems proper.

The bill abolishes the offices of Comptroller of the Treasury and all the Auditors for the several Departments, and substitutes therefor an Accounting Department, an establishment independent of the Executive Departments, under the direction of a newly created officer to be known as the "Comptroller General of the United States" whose powers shall comprise all those now conferred on the Comptroller of the Treasury and the several Auditors and, in addition, the investigation of all matters relating to the receipt or disbursement of public funds.

There is also created a joint committee of Congress to be known as "Joint Committee on Receipts and Expenditures of the Government," to consist of three members each of the Senate and House of Representatives, which committee shall investigate methods and procedure relating to the receipts and expenditures of the Government, recommend changes in laws and regulations, and accompany its recommendations by bill embodying same.

Engineering Research

The movement for Federal endowment of engineering and industrial research was revived early in the present Congress by the introduction of two bills into the Senate. The first, introduced by Senator Smith of Georgia, provides for the establishment of an engineering experiment station in each state, under the direction of and in connection with some university, engineering school, or land-grant college. The state legislature of each state is authorized to designate the institution best equipped to conduct the work but wherever the land-grant college has facilities approximately equal to those of the other institutions of the state, it shall be designated. All designations of institutions are made subject to the approval of the Secretary of Commerce.

The sums of $30,000, $40,000 and $50,000 for the first, second and third fiscal years respectively, and thereafter $50,000 annually, are appropriated to each state which by acts of its legislature assents to the provisions of this act The Secretary of Commerce is authorized to secure practical uniformity of methods by indicating such lines of work as shall be of importance from a military, naval, industrial or national standpoint, but responsibility for the conduct of the research shall rest with the individual experiment stations. Uniform standards of research are further provided for by making each experiment station a depository of the Department of Commerce and the Bureau of Standards, and the work of each station shall conform to the standards established by the U. S. Government.

The practical difficulty with the Smith bill is that it leaves open the question which has heretofore made it impossible to unite on any bill, namely, that the selection of the institution to receive the endowment is open to debate, and it will in too many cases depend on the influence each one may be able to muster in a state legislature. It opens up again the old contest between the state universities and the land-grant colleges by providing that the latter shall be selected if their facilities for conducting the work are equivalent to those of other institutions of the state. This again is a question leading to endless debate.

The second or Gronna bill sets up the Secretary of Commerce and the National Research Council as a "National Board on Engineering and Industrial Research" which shall appoint in each state and territory a state research board to consist of five engineers or scientists which shall have immediate supervision over the conduct of engineering and industrial research. Each state board shall utilize such laboratories, equipment and individuals as may be available in connection with any institution of learning within the state or territory, but before authorizing any investigations report shall be made to the Secretary of Commerce and authority to proceed shall be secured from the national board. The sum of $15,000 per annum is provided for expenditure in each state for the purposes aforesaid.

No statement can yet be made as to probabilities, but it is to be hoped that, in consideration of the matter that will soon take place, some opportunity will be afforded to present the real merits.

War Minerals Relief Commission

In Mechanical Engineering for May (p. 489) announcement was made of the appointment of a commission to review the claims of producers of manganese, chrome, pyrites and tungsten, who in their efforts to meet Government requirements during the war met with heavy losses. One thousand two hundred and eighty-seven claims with a total of over $18,000,000, were filed with the Commission prior to midnight, June 2, when the Act specified that the docket closed. An investigation, however, shows that a large number of the claims are subject to a material reduction, and the Commission believes that this reduction will permit the payment of all claims out of the $8,000,000, which was made available for this purpose.

The Commission is now making up a tour of mining centers at which hearings have been scheduled, and it is believed that the conduct of these hearings will require about three months. The Commission contemplates numerous difficult problems in administering the law. The most important, perhaps, is the interpretation of the "request or demand" of a Government agency which induced the claimant to undertake his venture. Important claims from various parts of the country and from the producers of different metals will be heard before the Commission makes its interpretation of this feature of the law. Since it is generally understood that this legislation was for the purpose of discharging moral obligations on the part of the Government, it is anticipated that the Commission will admit all claims in which it is shown that the claimant was responding to the general Government policy of stimulation.

NEWS OF THE ENGINEERING SOCIETIES

Reports of Meetings of Taylor Society, Heating and Ventilating Engineers, National Electric Light Association, Iron and Steel Institute, Engineering Society of Western Massachusetts, etc.

Taylor Society

IT was decided at a recent meeting of the Taylor Society to intensify and extend its activities, particularly along the following lines: The restoration of a recognized center of information and advice concerning scientific management; the classification and recording of data concerning the application of the principles of scientific management; the coördination of experiments and investigations; the publication of bulletins of standard practice and general pertinent information; the organization of machinery for lectures before industrial associations and educational institutions on the science and art of management; coöperation with educational institutions in determining the best methods of instruction in scientific management and in preparing material therefor; efforts to enlist the sympathy and coöperation of labor in the discovery and application of the best principles of management; and the development of a code of ethics to govern the practice of the consulting engineer in management and the administrator in both private and public service.

Provisions in the constitution were adopted to promote the increase of membership so as to include all who are seriously interested in scientific management. The affairs of the society have been placed in charge of Dr. H. S. Person who was elected Managing Director. The temporary New York headquarters of the society are in the Engineering Societies Building in space loaned by The American Society of Mechanical Engineers.

National Fire Protection Association

To promote the continued observance by the people of the United States and of Canada, both privately and in their occupations, of the measures for conservation of our natural resources adopted for the war emergency, was the import of the general resolutions adopted by the National Fire Protection Association at their twenty-third annual meeting in Ottawa, Ontario, May 6 to 8.

In its warfare against the needless sacrifice of human lives and property by fire, the association advocated the enactment of ordinances placing upon citizens who disregard fire-prevention orders the cost of extinguishing preventable fires, and a more general legal recognition of the common-law principle of personal liability for damage resulting from fires due to carelessness or neglect. Other measures recommended included the adoption by municipalities of the Standard Building Code of the National Board of Fire Underwriters; a wider general use of the automatic sprinkler as a fire-extinguishing agent, of the fire-division wall and of the life-saving exit facility; and the exclusive use of slow-burning motion-picture films, with national, provincial, state and local legislation to prevent the continued manufacture and distribution of material having the hazardous properties of the gun-cotton stock now commonly employed.

American Association of Engineers

Civic, social and legal problems affecting engineers were discussed at the fifth annual convention of the American Association of Engineers in Chicago, May 12 and 13. Of special importance was the report of the Compensation Committee of the Chicago Chapter, which contained detailed salary schedules submitted by the chapter to the national body with the suggestion that they utilize the data presented in a nation-wide and comprehensive study and seek to formulate a comprehensive schedule. This recommendation was approved by the convention, and the association is preparing to proceed with the work.

Changes made in the constitution were as follows: Junior members are given the right to vote; a new grade of membership called "candidate junior" is provided which requires but one year's education in a recognized technical college or one year of practical experience; a national practice committee is authorized, to report on questions of ethical policy and conduct; the latest past-president is to be a director; the board is authorized to make mutual agreements with other societies.

Dr. F. H. Newell, head of the department of civil engineering, College of Engineering, University of Illinois, was elected president of the association for the term 1919-1920. Dr. Newell is a member of the American Society of Civil Engineers, The American Society of Mechanical Engineers and the Western Society of Engineers, and is one of the original members of the Engineering Council.

Society of Heating and Ventilating Engineers

Among the various interesting committee reports presented at the semi-annual meeting of the American Society of Heating and Ventilating Engineers, held in Pittsburg, June 10 to 12, that of the Committee to Cooperate with the U. S. Navy Department is worthy of special mention on account of the researches undertaken by the committee in connection with the heating, ventilating and humidifying of battleships and submarines. The present system of heating submarines is by electricity. There are usually six electric heating units of two sizes, one taking 15 amperes and the other 25 amperes with a voltage varying from 110 to 115. These units draw energy from a storage battery. The committee, after investigating the characteristics of other systems of heating, such as combustion of smokeless powder, combustion of hydrogen and oxygen, combustion of acetylene and oxygen, and storage of heat in water and steam, have reached the conclusion that the system of heating by storage of heat in water can be advantageously substituted for the storage battery. They argue that a boiler of suitable capacity, capable of withstanding a pressure of about 300 lb. abs. per sq. in. could be installed in such a manner as to utilize the heat of the gases discharged by the engines when these are in operation. Such a boiler, containing about 3153 lb. of water, would store, they claim, about 1,135,000 B.t.u. which is equivalent to the number of heat units given out in 24 hours by the six electric heaters usually installed in a submarine boat. With an assumed total weight of 6000 lb. for the boiler and the water there would be a saving of 92.5 per cent of the weight required by a storage-battery equipment of equal heat-carrying capacity.

Some of the professional papers presented were: Classroom Ventilation, by Konrad Meier; Heating and Ventilating the Standard School House, by J. D. Cassell; Utilization of Sprinkler-System Piping for Heating, by A. W. Moulder; Heating and Ventilating Systems at the United States Government's Smokeless Powder Plant, at Nitro, W. Va., by G. W. Hubbard; Capacities of Reducing Valves for Steam-Heating Systems, by James A. Donnelly; and Cracking of Cast-Iron Sectional Hot-Water Boilers, by C. R. Honiball.

National Electric Light Association

The National Electric Light Association held its annual convention at Atlantic City, N. J., during the week beginning May 19. Municipal ownership, conservation of power resources and lamp production were the subjects discussed at the general sessions, the questions of prime movers, oil switches, underground construction and overhead lines being taken up at the technical sessions.

George Otis Smith, Director of the United States Geological

Survey, called attention to the difference in man power required by a steam plant and a hydroelectric plant, and cited the case of the Alabama Power Company, where the ratio was 84 to 1. The report of the lamp committee showed the total sales of incandescent lamps for domestic purposes, excluding miniatures, during 1918, to be 186,000,000, of which nearly 90 per cent were tungsten-filament lamps and the remainder carbon and "gem." The production of gem lamps, it was stated, has now been discontinued.

The committee on prime movers discussed in their report various phases of the problem of selecting turbines with proper regard to the size of the system as a whole, and included information as to the operating records of large-sized turbines, together with statements submitted by manufacturers reviewing progress during the past year. The development of power-station auxiliaries was treated at length and a wider use of boiler- and turbine-room instruments was recommended. Improvements in general design of hydroelectric installations were enumerated and the record of progress was noted.

The report of the committee on electrical apparatus covered particularly the control of fires in generators, some special phases of switchboard and transformer practice, substations with special reference to outdoor substations and automatic substations, power-factor correction, and apparatus for special fields, including electric furnaces, welding and the mining field.

In reference to underground distribution, the committee on this subject reported that a marked change had occurred in the load curve of central-station companies due to their taking on large blocks of load to serve industries working on a 24-hour basis. The result of thus obliging all classes of equipment to operate at a higher load factor than before, the committee asserted, has been an unusually large number of cable failures, with the resulting necessity for careful attention to the matter of rating cable capacities.

American Iron and Steel Institute

Optimism over the outlook in the iron and steel trades was expressed by Judge Elbert H. Gary in his opening address at the fifteenth general meeting of the American Iron and Steel Institute, held in New York on May 23.

Following Judge Gary's address several papers of technical interest were read. In a paper entitled Electrically-Heated Soaking Pits and Heating Furnaces, T. F. Baily, president of the Electric Furnace Co., Alliance, Ohio, considered the electric soaking pit for hot ingots as perhaps the most promising development of the electric furnace to the steel maker. Admitting that under ordinary circumstances when heating cold ingots electric pits could not compete in fuel economy with fuel-fired pits, he observed, however, that in the larger mills, when running at full capacity, features such as lack of uniformity in temperature of the heated ingot, excessive oxidation of the ingot and the like were often such as to quite outweigh the item of mere fuel. He said that the time was not far distant when substantially all modern mills rolling hot ingots would use electric pits for this part of steel-mill operation.

In a paper on the Present Status of Non-Metallic Impurities in Steel, Henry D. Hibbard, consulting engineer, Plainfield, N. J., discussed the occurrence and composition of solid non-metallic impurities or "sonims," and made reference to the experimental research so far completed by the committee on the elimination of sonims in steel instituted by the National Research Council, of which he is the chairman. In order to make steel as clean of sonims as practicable, the following rules were recommended:

1 Have the unfinished steel as free from oxides as possible at the end to diminish the work for the final additions to do and the quantity of sonims to be made by holding it without ore additions and with ample carbon and manganese in the bath. The manner and rate of boiling and the fracture of a slag sample will tell the furnaceman how his bath is in this respect. The "boil" must not be vigorous for the percentage of carbon in the metal.

2 Time must be allowed to elapse after the addition of the manganese for the sonims to be precipitated, or changed chemically as already noted, then to collect into globules or drops, and then to float to the top. Probably moderate agitation or stirring helps materially this gathering of sonims into drops of floatable size.

Other notable papers of technical interest were: Methods of Charging Raw Materials into the Blast Furnace, by J. A. Mohr, Superintendent, Currie Blast Furnaces, Carnegie Steel Co., Rankin, Pa.; Standardization of Shipbuilding Materials, by F. T. Llewellyn, Federal Shipbuilding Co., Kearney, N. J., and Chickasaw Shipbuilding Co., Mobile, Ala.; and Notes on Open-Hearth Practice, by H. M. Howe, professor emeritus, Columbia University, Bedford Hills, N. Y.

International Railway Fuel Association

Aspects of the fuel-conservation problem, both from the mechanical and operating standpoints, were extensively discussed at the eleventh annual meeting of the International Railway Fuel Association, which convened on May 19 in Chicago.

President L. R. Pyle drew a pertinent comparison between the service given by the railroads during the war and that which would be expected of them during the reconstruction period. To offset the increase in the cost of operation, he said, it is necessary to eliminate waste wherever it appears. All should bear in mind that practically everything done to save coal has a beneficial effect on all other angles of railroad operation.

The Committee on Pulverized Fuel reported that five American railroads—the Atchison, Topeka & Santa Fe, Chicago & Northwestern, Delaware & Hudson, Missouri, Kansas & Texas, and New York Central—have successfully operated during test periods individual locomotives equipped for and burning pulverized coal. The report quotes from some of the answers received by the committee to their request for information on results obtained from the tests made on locomotives. The following are notable instances:

a A carefully conducted test between two engines of the same class, one burning pulverized coal and the other hand-fired, showed that a saving of 23 per cent in fuel burned could be made by burning pulverized coal. The main difficulties encountered were the slagging over of the flue sheet and burning out of the brick arch. The former was largely overcome by an air jet to blow off the slag accumulations. A number of burner arrangements were tried, but it was found impossible to overcome the rapid burning out of the brick arch and the cost of replacing the arch brick practically equaled the saving in fuel. The delay to locomotives in replacing arch brick was also a decided drawback.

A comparison of total costs of hand firing versus pulverized-coal firing on the locomotives tested, which included cost of pulverizing, cost of handling, cost of arch manufacture, interest and depreciation, showed the hand firing to be most economical. In fairness to the pulverized coal, however, it was thought possible to design a firebox that would eliminate such troubles as burning out of the brick arch and show an advantage in favor of the pulverized coal.

b Burning pulverized fuel was very satisfactory; had all the steam that was wanted with splendid control all the time, burning 60 per cent anthracite and 40 per cent bituminous, the bituminous being necessary to increase the volatile. The question of economy is quite another thing and unless a poor or by-product coal can be purchased at a price that will absorb carrying charges, operation, etc., of a pulverizing plant and not exceed the price of a satisfactory lump coal, it should be given careful thought. There is no saving in the quantity of fuel used when pulverized, in fact, the difference is in favor of the lump coal. Pulverizing costs between 45 cents and 50 cents per ton.

From these and other answers received from pulverized-fuel installations operating on stationary engines, the Committee concluded that "the experimental work done and tests made, although still incomplete, have demonstrated the apparent soundness of the principle of burning coal in a finely divided form of suspension," but that "there are some things about pulverized coal" the Committee "are not satisfied with." They observe, for instance, that "it has not been clearly established that coal ground to the extreme fineness and dried to the extent recommended by most of the supporters of pulverized coal best meets the conditions of the practical user operating under widely diversified conditions," and that "the tendency of explosion and spontaneous combustion" has not been eliminated entirely.

Engineering Society of Western Massachusetts Organizes

The organization meeting of the newly formed Engineering Society of Western Massachusetts was held at Hotel Kimball, Springfield, on the evening of April 16. It was preceded by a dinner at which over 300 engineers representative of the various branches of the profession were present.

After dinner the meeting was called to order by George E. Williamson of the organization committee who briefly recited the history of the movement. The constitution and by-laws proposed and drawn up by the organization committee were then unanimously adopted as written and the following officers and directors unanimously elected:

President: Charles L. Newcomb, Manager, Am.Soc.M.E., Manager Deane Works, Worthington Pump and Machinery Corporation, Holyoke.

Vice-Presidents: C. C. Chesney, Fellow A. I. E. E., Manager General Electric Pittsfield Works; and George E. Williamson, Mem.Am.Soc.M.E., Chief Engineer, Strathmore Paper Co., Woronoco.

Secretary-Treasurer: Winfield E. Holmes, Mem.Am.Soc.M.E., Treasurer, Samuel M. Green Co., Springfield.

Directors: Dr. Herbert C. Emerson, Mem. Am. Chem. Soc., Springfield; Frank O. Wells, Manager Am.Soc.M.E., Greenfield; John C. Robinson, Springfield; E. E. Lochridge, Mem. Am. Soc. C. E., Springfield; Samuel M. Green, Mem.Am.Soc. M.E., Springfield; Geo. P. B. Alderman, Holyoke.

The meeting was then turned over to President Newcomb, who, in acknowledging the honor that had been conferred upon him, assured the society of his best efforts in the office to which he had been elected, and made a short address on the object and scope of the new organization, predicting for it an important and growing sphere in the community and the engineering world. It would have a purely engineering character, he said, but would embrace engineers of all branches. The American Society of Mechanical Engineers had thought well enough of the movement to have its Sections Committee present, and President Cooley would have attended but was unavoidably detained. Secretary Rice had also telegraphed from Denver expressing his regret at being unable to carry out his intentions of being present, and conveying his compliments to the new society. It was hoped to soon receive like recognition from all the national engineering societies.

Prof. L. P. Breckinridge of Yale University, who was then introduced, complimented the society upon its efforts to bring the various branches of engineering into one local organization, predicting that in the future the national organizations would get together in a great engineering body, and that it would then be pointed out that western Massachusetts had done the same thing in 1919.

William Spencer Murray, consulting engineer of New York, and who electrified the New Haven Railroad and the Hoosac Tunnel, spoke upon conservation and described a project he had been developing for the Secretary of the Interior which involved large-scale development of hydroelectric power and electric power at the pit mouth and the installation of a super-power distributing line from Washington to Boston. Mr. Murray submitted data upon the enormous consequent saving in coal and reduction of power cost in the region served by the proposed super-power line, and showed the gathering of engineers the entire feasibility of Secretary Lane's plan.

Dr. George Otis Smith, director of United States Geological Survey, followed Mr. Murray and furnished valuable data relating to the proposed super-power line, amplifying, substantiating, and further explaining his statements.

The meeting then adjourned with many additional applications for membership.

The objects of the society as stated in the constitution are—"The professional improvement of its members; the advancement of the arts and sciences connected with the various branches of engineering; the promotion of civic righteousness and truth and the participation in affairs of an engineering nature which affect the interest of the public." Headquarters will be in Springfield and regular meetings will be held in the various cities and communities of western Massachusetts.

The early history of the Engineering Society of Western Massachusetts really dates back to some two or three years ago, when it was proposed to organize a local section of The American Society of Mechanical Engineers in Springfield and vicinity. The matter was taken up again this year when Calvin W. Rice, Secretary of the A. S. M. E., and William G. Starkweather, Chairman of its Boston Section, conferred at the Hotel Kimball with Messrs. George E. Williamson, William J. A. London, C. W. Burges, and Winfield E. Holmes. After thoroughly canvassing the local situation Mr. Rice suggested that a regional engineering society be formed that would appeal to and embrace not only mechanical engineers but engineers of all branches.

This preliminary committee of four met again the following week and each was in agreement that the new engineering society

C. L. Newcomb
President

C. C. Chesney
Vice-President

G. E. Williamson
Vice-President

W. E. Holmes
Secretary-Treasurer

Officers of the Engineering Society of Western Massachusetts

should be inaugurated. Thereupon twenty other local engineers, architects, and chemists, were asked to participate in a conference on the subject, which was done January 21, 1919. At a later meeting, on February 17, the organization committee completed much of its preliminary work and made arrangements for the initial meeting on April 16.

Colorado Engineering Council

At a specially arranged meeting of the Colorado sections of the founder engineering societies and other local scientific organizations, held at Denver on May 16, the final form of the constitution of an association to be known as the Colorado Engineering Council was discussed and adopted. The purpose of this council is to coördinate the work of various technical, scientific and engineering organizations, to promote the welfare and professional standing of their members, and to foster a more general recognition of the engineer in civic matters. All local scientific associations are eligible for membership in the Council.

PROPOSED REORGANIZATION OF THE AMERICAN ENGINEERING STANDARDS COMMITTEE

At the present time many bodies are engaged in the formulation of standards. There is no uniformity in the rules for such procedure in the different organizations; in some cases the committees engaged in the work are not fully representative, and in a considerable proportion of cases they do not consult all the allied interests. The present custom results in a considerable duplication of work, and there are in some fields several "standards" proposed for the same thing that differ from each other only slightly and that often in unimportant details. It is very much more difficult to obtain agreement between proposers of overlapping standards after they have been published than it would be to get the proposers to agree before they had committed themselves publicly.

The American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials, appointed a committee to consider the advisability of coöperating in engineering standardization, upon whose recommendation the American Engineering Standards Committee was formed, with a membership consisting of representatives of the five societies mentioned.

The American Engineering Standards Committee has held a series of meetings for the purpose of revising the constitution, and the following communication containing the proposed constitution is being sent to members of the Council of The American Society of Mechanical Engineers and to the governing boards of the other Founder Societies which were instrumental in organizing the American Engineering Standards Committee.

To the Council of

The American Society of Mechanical Engineers

Gentlemen:

At a regularly called meeting of the American Engineering Standards Committee held on May 17, 1919, a proposed revision of its constitution was approved by the committee. In submitting this revised constitution to your board for its approval, we desire to give the reasons and to offer some explanations for the proposed changes in the present constitution of this committee.

Soon after its formal organization on October 19, 1918, the committee began its work under the present constitution. But it became evident immediately that some organizations and societies were not willing to coöperate under the existing form of organization. This feeling was also expressed very freely and positively at a conference held in Washington on January 15, 1919. On this date representatives of more than one hundred organizations, including federal, state and municipal boards, who are interested, in the formulation of safety codes, met to consider how they might coöperate to develop these codes in an efficient and generally satisfactory manner. The objects of the five societies in organizing the American Engineering Standards Committee and the committee's method of procedure were very fully and carefully presented to this conference. The discussion which followed, however, indicated a feeling, especially among some large national organizations which have for some years been developing safety codes, that the present method of selecting representatives to this committee is not broad enough to permit them to coöperate completely.

Following this Washington conference a number of meetings and conferences between the American Engineering Standards Committee and other organizations interested in the development of standards were held. These meetings have convinced this committee that, if its work is to receive nation-wide, general, and immediate acceptance, some changes in its constitution are necessary.

The most important of these is contained in Sections 8 and 9. They state that the proposed Association starting with a membership consisting of representatives of the five Founder Societies and Government Departments may add representatives from other organizations or groups of organizations. To permit this enlarged committee or association to function easily, Article V provides for a Board of Directors of twelve members of the Association.

It should be stated here, however, that the objects for which the committee was originally organized, though restated in the proposed new constitution, are exactly the same. We desire especially to call your attention to Section 4. This is a definite declaration of the Association's policy of non-interference with the absolute autonomy of any group engaged in the development of a standard. The failure to recognize this is responsible for much of the misunderstanding and fear of interference that has found expression in the technical press, and even by well-meaning, but misinformed members of already affiliated organizations.

Article VII on the "Development and Approval of Standards" now states in no uncertain terms what has always been the intent of those instrumental in the organization of the Committee, viz., it will be entirely optional on the part of the organizations having representation on the new Association, to submit their existing standards and those developed in the future for the approval of the American Engineering Standards Association. But it is hoped that as the Association develops and its policies become well understood, the advantages of this approval will become so apparent that all societies and organizations producing standards will desire to submit their standards for approval. This article of the revised constitution further provides that full credit and recognition for its work in producing a standard will be given to the sponsor society or organization producing it, and the standard will be known by the name assigned to it by the sponsor society.

Trusting that you will consider carefully, and finally approve these proposed changes in our Constitution, we remain

Very respectfully,

American Engineering Standards Committee,

George C. Stone,

Vice-Chairman.

Proposed Changes in the Constitution of the American Engineering Standards Committee

The Constitution of the American Engineering Standards Committee shall be changed to read as follows:

Article I. Name

Sec. 1. The name of this association shall be the American Engineering Standards Association, hereinafter referred to as the Association.

Article II. Objects

The objects of the Association shall be:

Sec. 2. To unify and simplify the methods of arriving at engineering standards, to secure coöperation between various organizations, and to prevent duplication of standardization work;

Sec. 3. To promulgate rules for the development and approval of standards;

Sec. 4. To receive and pass upon recommendations for standards submitted as provided in the Rules of Procedure, but not to initiate, define, nor develop the details of any particular standard;

Sec. 5. To act as a means of intercommunication between organizations and individuals interested in the problems of standardization;

Sec. 6. To give an international status to American engineering standards.

Sec. 7. To coöperate with similar organizations in other countries and to promote international standardization.

Article III. Membership

Sec. 8. The Association shall be composed of not more than three representatives from the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Society for Testing Materials, the Government Departments of War, Navy, and Commerce, and from each of such other organizations or groups of organizations as may be approved as hereinafter provided. The vote of the Association shall lie with these representatives, who shall be termed members. Each member shall have one vote.

Sec. 9. The Association may, upon a majority vote, invite any organization or group of organizations to join in its work. This vote of the Association shall be by letter ballot.

Sec. 10. Any organization or group of organizations desiring representation in the Association shall make formal application therefor in writing, setting forth the scope of its standardization interests and activities and the number of its members. This application shall be considered at the next regular meeting of the Board of Directors and, upon a majority vote, shall be submitted to the Association. The Association shall vote on the application by letter ballot which shall be drawn upon the recommendations of the Board of Directors and shall state whether one, two, or three representatives are recommended. Upon a majority vote of the Association the organization or group of organizations making application shall be requested to appoint representatives not exceeding the specified number, who shall become members of the Association after properly qualifying.

Sec. 11. The number of representatives any organization or group of organizations is requested to appoint shall be determined by such considerations as: the volume, character, and importance of its standardization work, if any, together with its standing and total membership.

Sec. 12. Any organization or group of organizations appointing representatives to the Association shall agree to assume the financial obligations herein set forth and to abide by the Constitution, By-Laws, and Rules of the Association. In the case of members appointed by the Government, State or Municipal departments or bureaus, it is

understood that financial support is not expected until such time as proper authorization therefor can be obtained.

Sec. 13. Initially, each organization or group of organizations shall appoint its first representative to serve three years, the second to serve two years, and the third to serve one year. After the first year all appointments shall be for three years.

Sec. 14. A member whose term of office has expired may be reappointed. A vacancy shall be filled by the organization or group of organizations from which the retiring member was originally appointed, such appointment to be for the unexpired term.

Sec. 15. Any member may resign from the Association upon written notification to the Secretary. Any organization or group of organizations may withdraw its representatives from the Association upon notice in writing to the Secretary, provided the dues for the current calendar half-year have been paid.

Sec. 16. Any organization or group of organizations in arrears for dues for more than one year will thereby lose its right to representation in the Association.

ARTICLE IV. OFFICERS

Sec. 17. At its Annual Meeting the Association shall elect a Chairman and Vice-Chairman from its membership. Officers so elected shall serve for one year, or until their successors are elected. These officers shall not serve for more than three consecutive terms. Vacancies may be filled by election at any regular or special meeting, provided notice has been given in the call for the meeting.

Sec. 18. A Secretary shall be engaged by the Board of Directors.

Sec. 19. The Chairman shall be the executive officer of the Association, shall approve all expenditures and countersign all vouchers. He shall preside at all meetings of the Association. He shall be ex-officio member of all committees and Chairman of the Board of Directors. In the absence of the Chairman his duties shall be taken over by the Vice-Chairman, and in the absence of both, by a member of the Board of Directors.

Sec. 20. The Secretary shall perform all duties usual to the office of a secretary, shall maintain a file of information on and in connection with standards, a list of organizations interested in standardization work, and such other information as may be necessary for the work of the Association. He shall have sufficient authority to conduct the routine business of the Association under such instructions as may be from time to time given him by the Board of Directors.

ARTICLE V. BOARD OF DIRECTORS

Sec. 21. The affairs of the Association shall be managed by a Board of Directors elected from the membership of the Association at its Annual Meeting.

Sec. 22. The Board shall consist of not more than twelve members, and shall not include more than one representative from any one organization or group of organizations.

Sec. 23. The Board shall be the legal trustee of the property of the Association and shall have power to deal with all affairs of the Association except that of approving "Recommended Practices," "Tentative Standards" or "Standards of the American Engineering Standards Association."

Sec. 24. The Board may, by resolution, delegate any of its powers to committees or to any one or more of its members, but no act of such committee or delegates shall be binding upon the Association until it has been approved by the Board.

Sec. 25. All suggestions, inquiries, or complaints as to the purposes, objects, or methods of this Association shall be referred to and answered as directed by the Board of Directors.

Sec. 26. The Board shall submit a report at the Annual Meeting describing the work done in the past fiscal year and showing the financial condition of the Association. An abstract of this report shall be entered in the minutes of the meeting.

Sec. 27. A quorum of the Board of Directors shall be a majority of its membership.

ARTICLE VI. MEETINGS

Sec. 28. The Association shall hold the Annual Meeting in the month of November. It may hold additional meetings at any time either at the call of the Chairman or upon written request of not less than ten members. The call for a meeting shall be mailed to each member of the Association at least ten days before the date set for the meeting.

Sec. 29. A quorum of the Association shall consist of a majority of its members.

ARTICLE VII. DEVELOPMENT AND APPROVAL OF STANDARDS

Sec. 30. The Association shall formulate rules under which committees to create standards shall be constituted and organized.

Sec. 31. The Association shall receive and pass upon recommendations for standards which may be submitted by any competent body.

Sec. 32. Any proposed standard approved by the Association shall be known as a "Recommended Practice of the American Engineering Standards Association," or as a "Tentative Standard of the American Engineering Standards Association," and when in the opinion of this Association it has proved its suitability, it shall be known as a "Standard of the American Engineering Standards Association." In every case publication shall bear the title assigned to the standard by the Sponsor organization and the name of the Sponsor followed by the statement: "Approved as Recommended Practice, Tentative Standard, or Standard of the American Engineering Standards Association."

Sec. 33. The approval as "Recommended Practice" or as "Tentative Standard" of any standard submitted to the Association shall require the affirmative vote of three-fourths of the Association; the advance of status to "Standard" shall require an affirmative vote of 90 per cent. of the Association. Such votes shall be by letter ballot. Letter ballots may be ordered at any regular or special meeting of the Association, or at any meeting of the Board of Directors.

ARTICLE VIII. FINANCES

Sec. 34. Each organization appointing representatives to the Association shall pay annual dues of $500.00 for each representative. These dues shall be paid semi-annually.

Sec. 35. Other funds may be obtained in any manner approved by the Association.

Sec. 36. Funds of the Association shall be in the custody of the Secretary, who shall be placed under suitable bond, and they shall be disbursed by him upon vouchers countersigned by the Chairman or Vice-Chairman.

Sec. 37. The fiscal year of the Association shall terminate with the 31st day of December.

ARTICLE IX. AMENDMENTS

Sec. 38. Amendments to this Constitution must be proposed in writing at least thirty days before the meeting of the Association at which they are to be voted upon, this vote to be upon the amendment as originally proposed or as further amended at the meeting. If passed by a two-thirds majority of those present they shall be referred to the Governing Boards of all the organizations or groups of organizations represented in the Association, and shall become operative only when they have been approved by the organizations or groups of organizations appointing at least two-thirds of the membership of the Association.

HONORARY MEMBER OF A. S. M. E. RECEIVES JOHN FRITZ MEDAL

MAJOR-GENERAL GEORGE W. GOETHALS, upon whom was conferred Honorary Membership by The American Society of Mechanical Engineers at its 1917 Annual Meeting, was accorded on the evening of May 22 the further distinction of receiving the John Fritz Medal for his achievements in building the Panama Canal. The exercises were held in the auditorium of the Engineering Societies Building, New York City, Charles F. Rand, past-president of the American Institute of Mining and Metallurgical Engineers and Secretary of the Board of Award, presiding in the absence of Clemens Herschel, past-president of the American Society of Civil Engineers, Chairman of the Board. As is well known, this medal was established in 1902 in honor of the great American engineer, John Fritz, who was also the first recipient of the medal. A board representing the four national engineering societies—the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers—awards the medal not oftener than once a year for notable achievement along engineering lines. Other distinguished recipients of the John Fritz Medal have been: Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas A. Edison, Charles T. Porter, Alfred Noble, Sir William H. White, Robert W. Hunt, John E. Sweet, James Douglas, Elihu Thomson, Henry M. Howe and J. Waldo Smith.

A fitting tribute was paid by William L. Saunders, past-president of the American Institute of Mining and Metallurgical Engineers, to the perseverance, skill, tenacious application and devotion to duty by which General Goethals brought to a successful termination the building of one of the greatest engineering works ever undertaken in history. After briefly reviewing the military career of General Goethals from the time he was appointed second lieutenant at West Point on June 12, 1880, and his later experience as instructor in civil and military engineering in the United States Military Academy, Mr. Saunders concluded with the following impressive remarks:

It has been said that fame comes to a man who is thinking about something else. The chief difference, it seems to me, between common men and big men is in the sense of self-effacement. When a man thinks of himself in his actions in life, he forgets the things that make men great. A thing done for the sake of self-glory or self-profit is only half done; it is only half-baked. It bears the savor of unripe fruit or the taint of decay. A thing to be well done must be well done;

and nothing is done well that does not carry with it the spirit of self-sacrifice in the material or human interests of others.

And so, in giving this token of our esteem tonight to General Goethals, do we honor the man as well as the engineer. We pay this tribute of our admiration and our tears to a great public servant, who, through a long period of inextinguishable devotion to public duty, a period of hard labor, has risen, rung by rung, up the ladder of St. Augustine.

"For the heights by great men reached and kept
Were not attained by sudden flight:
But they, while their companions slept,
Were toiling upward on the night."

Hon. Henry L. Stimson, Secretary of War for a considerable period of time during which the canal was under construction, spoke in part as follows:

The time when I began to have duties in regard to the canal, the period of my service, covered the years 1911 and 1912. At that time the work was in full swing, at its maximum capacity. The long delays and troubles which had marked the beginning had been overcome. The long discussion over the different types of canal, whether it should be a sea-level or a lock canal, had been settled before by the characteristic decision of Mr. Roosevelt. The dreaded scourge of the yellow fever, which had caused many delays in the early years, had been banished forever by the work of Colonel Gorgas and the Medical Corps. The organization of the working forces had been perfected, and the giant machinery was there and in full swing.

Of course, there were many problems meeting the Chief Engineer every day, but, nevertheless, the machine was then working at its fullest capacity; and for that very reason, perhaps, it was possible at that time to see, as at no other time, how the whole work depended and swung upon the character and the force of one man. . . .

By the inexorable necessity of events, there had been an evolution into one man control, and the result of that evolution was Goethals, and the Canal then represented throughout, in every part of its working force, the impress of his personality. The authority which he exercised there was comparable only to the authority of the commander of an expeditionary force in a foreign country; but even that was only a comparison, because he came into contact with his men in a direct, personal way which I have never seen exemplified in the commander of a combatant division.

Ambrose Swasey, past-president of The American Society of Mechanical Engineers, in making the formal presentation of the medal addressed General Goethals and said:

Sir, Major-General George Washington Goethals, Builder of the Panama Canal, we are gathered here to do honor to you, and in so doing we honor ourselves and all those whom we represent.

In a time of peace you went to war with the elements; and with the forces at your command you won for civilization one of the greatest victories of the age.

Whenever your country has called, that high standard of service has been your response—a service you have loyally and faithfully wrought into all your achievements as a soldier; as an engineer; as a man.

On behalf of the Board of Award I have the honor to present to you the John Fritz Medal.

In responding General Goethals paid a tribute to "others who should receive recognition and mention" in connection with the building of the Panama Canal, chief among them being the late Colonel Roosevelt, through whose "persistent efforts . . . the necessary legislation, authorizing the construction of the canal, was due," and who "had the far-sightedness and the courage, after convening an international board of engineers, to repudiate the recommendation of the majority, accept that of the minority and advocate to Congress the construction of a lock canal." General Goethals recalled the work of the doctors "who exhibited the highest type of moral courage when they demonstrated the fact that the mosquito was the transmitter of yellow fever" and who "laid down the principles which ultimately resulted in the eradication of yellow fever from the Canal Zone." He also referred to "the vast number of engineers, employed in this country, who gave the best that was in them in designing the various forms of machinery which were used in the construction work, and, subsequently, machinery employed for the operating of the locks, the lighting of the canal, the handling of our coal, and the operation of our dry-dock"; and to the 50,000 American workmen, every one of whom "was imbued with the idea that the particular part of the work on which he was engaged was absolutely necessary" to the success of the undertaking, and without which the canal would have been a failure.

NECROLOGY

CHARLES MILTON BALDWIN

Charles M. Baldwin, Lieutenant in the United States Navy, died at sea on March 12, 1919. Lieutenant Baldwin was born on March 26, 1876, in Mt. Vernon, Tex., and attended the Southwestern University at Georgetown. He was formerly connected as assistant marine engineer with the Mallory, Red D and Southern Pacific lines. For twelve years, 1903 to 1915, he served in the United States Navy, first as machinist and later as warrant machinist, with a chief engineer's unlimited ocean license. When the United States entered the war he again offered his services and was commissioned a lieutenant in the Navy. He had also served in the Spanish-American War and in the Philippine and Mexican campaigns.

Lieutenant Baldwin was a member of the National Marine Engineers' Beneficial Association, and belonged to a number of fraternal organizations. He became an associate-member of the Society in 1905.

LESTER WARREN COGSWELL

Lester W. Cogswell was born in January, 1880, at Charlestown, Mass. He was educated in the public schools of that city and was graduated from the Mechanics High School.

In 1898 Mr. Cogswell obtained employment in the engineering department of the B. F. Sturtevant Co., Jamaica Plain, Mass., where he served a two-year apprenticeship. Later he was associated with the following firms: the Mason Regulator Co., Dorchester; the Blake Pump Works, East Cambridge; the United Shoe Machinery Co.; the Sub-Target Gun Co.; the Walworth Manufacturing Co.; the Globe Ore Reduction Co., and the United Printing Machine Co., all in Boston.

In the latter part of 1916 Mr. Cogswell became connected with the Kinney Manufacturing Co., also in Boston, where he held the position of designer of engines and rotary pumps. He was with this concern at the time of his death, September 29, 1918.

Mr. Cogswell became an associate-member of the Society in 1917.

WILLIAM W. DINGEE

William W. Dingee was born on January 5, 1831, in Byberry, Pa. He was educated in the Maryland Institute and also attended the School of Mechanical Arts connected with the Institute.

For thirty years Mr. Dingee was the proprietor and superintendent of a foundry and machine business, where he designed, built and operated many machines for general and special purposes. For many years he was associated with the J. I. Case Threshing Co., Racine, Wis., as machine designer and constructor, and while with this concern was the inventor of many improvements for threshing machines.

Mr. Dingee retired from active business in 1906 and the last years of his life were spent in Chicago where he died on May 25, 1919. He was one of the early members of the Society, having joined in 1886.

WALTER ERLENKOTTER

Walter Erlenkotter, vice-president of the Secaw Chemical Co., Irvington, N. J., died on May 14, 1919. Mr. Erlenkotter was born on August 22, 1887, in Hoboken, N. J. He received his early education in the Hoboken Academy and was graduated from Stevens Institute of Technology in 1908. He was formerly connected with J. G. White & Co., New York City, in the design and construction of steam-engineering plants, etc., and later held the position of fuel-engineering chemist in charge of the Central Testing Laboratory, Bureau of Contract Supervision, New York City, where his work dealt with physical tests, sampling, coal analysis, the design of new apparatus, etc. In the latter part of 1916 he became chief engineer for the Secaw Chemical Co. and was subsequently advanced to the position of vice-president. Mr. Erlenkotter became a junior member of the Society in 1912 and in 1916 was promoted to the grade of associate-member.

JAMES J. FLYNN

James J. Flynn was born in April, 1893, in New York City. He was educated in the public schools of the city and was graduated from the Mechanics' Institute. In 1908 he started work for the Western Electric Co., taking their regular students' course and spending six months in their manufacturing department.

He was then transferred to the tool and gage-inspection department where he was located for about five years; he was then placed on construction work of telephone equipment on the road. After

seven years with this concern, Mr. Flynn became associated in 1915 with the Remington Arms Bridgeport Works as assistant low-tension engineer. The following year he was made foreman inspector of the barrel department and in 1918 he became chief inspector of ordnance for the U. S. Government in the same company.

Mr. Flynn became a junior member of the Society in 1918. He died on February 11, 1919.

RICHARD HUMPHREY HUGHES

Richard H. Hughes, vice-president and general manager of the Crescent Portland Cement Co., Wampum, Pa., and a member of the Board of Directors of the Portland Cement Association, died on April 12, 1919.

Mr. Hughes was born on September 16, 1862, in Lima, Ohio. He received his education in the schools of that city and also served there his appenticeship in railroad engineering. In 1901 he became connected with the Portland Cement Co. and took charge of the remodeling of their plant. During the year 1908 and 1909, in co-operation with Mr. W. B. Ruggles of the Ruggles-Coles Engineering Co., he had entire charge of the designing and building of the company's 3000-barrel plant and upon its completion, of its operation, alteration and additions.

Mr. Hughes belonged to a number of social and fraternal organizations. He became an associate-member of the Society in 1914.

THEODORE H. GUETHING

Theodore H. Guething, Lieutenant in the Ordnance Department of the Army, was born on October 15, 1891, in Winchester, Mass., where he received his early education. He attended Exeter Academy for three years and then entered the Massachusetts Institute of Technology, from which he was graduated in 1915 with the degree of B.S.

Theodore H. Guething

He was connected for short periods with the Haughton Elevator Co., Toledo, Ohio, and with the Anaconda Mining Co., Anaconda, Mont. In June 1916 he became associated with the John A. Stevens Engineering Co., Lowell, Mass., where he was assistant in the analysis of the power plant of the Stevens Manufacturing Co., Fall River, Mass., assistant superintendent of the construction of the power plant for the North & Judd Manufacturing Co., New Britain, Conn., and assistant engineer on motoring, Chelsea Fiber Mills, Brooklyn, N. Y.

When the United States entered the war he offered his services to the Government and was commissioned a first lieutenant in the Ordnance Department of the Army. He was assigned to the Picatinny Arsenal, Dover, N. J., as mechanical engineer in charge of the shops and as motor-transport officer, and was working in this capacity when he contracted influenza-pneumonia and died on October 16, 1918.

Lieutenant Guething became a junior member of the Society in 1917.

ERNEST G. MARBLE

Ernest G. Marble, who, until 1918, was general sales and works manager of the American Engineering Co., Philadelphia, died on May 6, 1919. Mr. Marble was born on September 19, 1876, in Methuen, Mass., and was graduated from Tufts College in 1899. Shortly after he became connected with the Otis Elevator Co. as superintendent of construction of their Philadelphia works, and from 1907 to 1912 was treasurer of the American Ship Windlass Co., with full charge of the manufacturing and financial interests of the concern.

Mr. Marble became associated with the American Engineering Co. in 1912, resigning in the spring of 1918 because of ill health. He became a member of the Society in 1909.

CHARLES W. PRARAY

Charles W. Praray was born on May 29, 1873, in Pawtucket, R. I., and was educated in the public schools of that city. He served an apprenticeship in one of the local cotton mills and for ten years was connected with the B. B. & R. Knight Cotton Manufacturing Co. as master mechanic and engineer. For several years he was master mechanic for the Manomet Mills in New Bedford, Mass., when he became associated with the Holmes Manufacturing Co., also in New Bedford, as superintendent and architect.

About twelve years ago he opened a mill engineer's and architect's office in New Bedford and proved highly successful in his work. He was the designer of some six or seven mills in New Bedford and of a great number of others throughout New England. He was actively connected with this work at the time of his death, March 22, 1919.

Mr. Praray held a first-class Massachusetts engineer's license. He was a member of the National Association of Cotton Manufacturers and of a number of social clubs. He became a member of the Society in 1918.

HENRY S. HAYWARD

Henry S. Hayward, Lieutenant, U. S. Naval Reserve Force, was born on December 25, 1876, in Elizabeth, N. J. He was a 1900 graduate of Stevens Institute of Technology.

Henry S. Hayward

His first position was in the drafting room of the Pennsylvania Railroad, Jersey City, N. J. He was next associated with the Franklin Air Compressor Co., Franklin, Pa., as chief engineer, his work consisting of designing and supervising the construction of their power plant. From 1902 to 1905 he was in business for himself as a mechanical engineer, handling mechanical mill supplies.

In 1906 he became assistant to the vice-president of the Franklin Railway Supply Co., manufacturing and promoting special mechanical devices for locomotives. Prior to his enlistment in 1918 he was president of the Roybel Packing Co., N. Y.

He was commissioned a lieutenant (j.g.) in the Naval Reserve Force and was stationed at the Charleston Navy Yard, Charleston, S. C. He was north on a twenty-day furlough when he contracted pneumonia and died on March 31, 1919.

Lieutenant Hayward became a member of the Society in 1900.

CHARLES JAMES REILLY

Charles James Reilly, Sergeant, Co. C, 21st Engineers, A. E. F., was killed in France, on September 1, 1918, by a bomb dropped from a German airplane, which, according to report, was flying low over the camp and bearing the Allies' colors.

Sergeant Reilly was born on September 10, 1887, in Louisville, Ky. He received his early education in the schools of that city and was graduated from the high school in 1905, when he entered Rose Polytechnic Institute, from which he received his B.S. degree in mechanical engineering in 1909. For three years he was connected with the Louisville & Nashville Railroad in Louisville, Ky., as a machinist in their locomotive-erecting shop. His next position was with the Vandalia Railroad, Terre Haute, Ind., as draftsman in the motive-power department, where he remained for a little over three years, resigning to become connected with the U. S. Division of Valuation of the Interstate Commerce Committee as junior mechanical engineer, where his work dealt with the valuation of the mechanical property of railroads. In April 1916 he became assistant to the superintendent of the Sandusky Cement Co., Bay Ridge, Ohio, where he was employed at the time of his enlistment, July 1917. He was sent to Camp Grant, Ill., for training and in January 1918 went to France as a member of Company C, 21st Engineers.

Sergeant Reilly became an associate-member of the Society in 1916.

AUGUST S. LINDEMANN

August S. Lindemann, secretary and treasurer of the Milwaukee-Waukesha Brewing Co., who died in the early part of 1919 was born in Milwaukee, Wis., in June 1866. He was graduated from the University of Wisconsin in 1885 with the degree of B.M.E. and in 1887 received his master's degree in mechanical engineering.

He served an apprenticeship as machinist with Filer & Stowell and with E. P. Allis & Co., both firms in Milwaukee. He was employed in the drafting room of Flanders & Bottum for one year when he became connected with the Pfister & Vogel Leather Co. as erecting engineer. From 1889 to 1898 he was associated with J. P. Lindemann, first as erecting engineer and later as designer and constructor of new stamping and metal-forming machinery. His next position was

with the Milwaukee-Waukesha Brewing Co., as manager and general superintendent, designing and developing machinery used in bottling works. His advancement was rapid and at the time of his death he held the position of secretary-treasurer of the company.

Mr. Lindemann became a member of the Society in 1913.

WILLIAM TRIMBLE WHEELER

William T. Wheeler, actively connected with the Trinity Engineering Co. and the Diamond Carbonating Co., both of New York City, died on April 27, 1919. Mr. Wheeler was born on August 22, 1862, in Calais, Me., and was educated in the public schools of that city and Pratt Institute, Brooklyn.

For the first twenty years of his business life he was associated with the Equitable Life Insurance Co., in charge of installing the steam, electrical and elevator plants in their buildings, both here and abroad. Later he was connected with the New York Life Insurance Co., as chief engineer of their building in New York City, and still later in charge of the installation of the elevator, electric-light and steam-heating plants for the H. O'Neil Co., New York.

Mr. Wheeler became a member of the Society in 1905.

ELIAS QUEREAU HORTON

Elias Q. Horton, Lieutenant (j.g.), U. S. Naval Reserve Force, died of influenza-pneumonia on March 4, 1919. Lieutenant Horton was born in Ossining, N. Y., on July 28, 1884. He was educated in the public schools of New York City, Stevens Preparatory School and Stevens Institute of Technology, from which he was graduated in 1905 with the degree of M.E.

Elias Q. Horton

Upon graduation he became associated with the Otis Elevator Co., New York, and gained his shop experience in their factory at Yonkers. He was then transferred to the estimating department and in 1908 he was made assistant chief estimator. In 1910 he was made assistant manager in Oklahoma City, in charge of all sales in the state. His advancement was continuous and rapid until, at the time of his enlistment in April 1917, he was in charge of the Washington office of the company.

He enlisted in the Naval Reserve Force and was assigned to active duty as coxswain in Newport, R. I. In June of that year he was sent to Annapolis for special training, and at the termination of the course was commissioned as ensign. He was ordered to duty on the U.S.S. *South Carolina*, where he served as junior watch officer, division officer and communicating officer, respectively. He was then promoted to the rank of lieutenant (j.g.). Shortly before his death he was ordered to the Receiving Ship *Philadelphia*, where he was to have been discharged and to have rejoined the staff of the Otis Elevator Co.

Lieutenant Horton was a member of the Sons of the Colonial Wars, the Sons of the Revolution and of a number of clubs. He became a junior member of the Society in 1912.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by July 15 in order to appear in the August issue.

CHANGES OF POSITION

E. A. Hitchcock has recently become connected with the Bailey Meter Company, of Cleveland, Ohio, as vice-president. He will supervise the training of technical graduates for the company's service and sales departments. During the past six years he has been associated with the E. W. Clark and Company Management Corporation, Columbus, Ohio, as advisory consulting and power sales engineer.

G. A. Trube, formerly associated with the Westinghouse Air Brake Company, Pittsburgh, Pa., as expert manager, has become connected with Gaston, Williams and Wigmore, of New York.

F. W. Teele has assumed the duties of general manager of the Mexican Light and Power Company, Mexican Tramways Company and allied interests at Mexico City, Mexico. He was, until recently, associated with the Southern Canada Power Company, Ltd., Montreal, Canada, in the capacity of vice-president and managing director.

Cleveland C. Soper has resigned his position of instructor of machine design, Wentworth Institute, Boston, Mass., and has accepted the position of engineer with the Kent Machine Company, Kent, Ohio.

Frederick C. Fladd's name was inadvertently omitted from the 1919 issue of the Year Book. Mr. Fladd is connected with the E. W. Bliss Company, of Brooklyn, N. Y., in the capacity of traveling and consulting engineer.

Arthur E. Anderson, formerly chief engineer, The Intermountain Railway, Light and Power Company, Denver, Colo., has assumed the position of general superintendent of The Grand Junction Electric, Gas and Manufacturing Company, and The Grand River Valley Railway Company, Grand Junction, Colo.

A. L. Roberts, formerly designing engineer with the Bethlehem Steel Company, has been elected president of The Roberts Company, Philadelphia, consulting and contracting mechanical engineers, and V. F. Signorelli, formerly secretary and treasurer of Southwark Foundry and Machine Company,, has been elected secretary and treasurer. The company has recently been incorporated under the laws of the State of Pennsylvania.

Charles E. Burgoon has completed his work with the Air Nitrates Corporation, New York and Muscle Shoals, Ala., and has accepted the position of senior examiner in the cancellation department of the Emergency Fleet Corporation, Philadelphia, Pa.

H. O. C. Isenberg has severed his connection with the Wright-Martin Aircraft Corporation, New Brunswick, N. J., as factory manager, and has accepted the position of general manager of factories at Ilion, Syracuse and Bridgeport, Conn., of the Remington Typewriter Company.

Frank D. Shumate who has been with the Worthington Pump and Machinery Corporation for a number of years, has assumed the duties of vice-president and sales manager of the Chalmers Pump and Manufacturing Company, which has recently been organized. Mr. Shumate and associates have purchased the entire pumping machinery business of the Canton-Hughes Pump Company, merging it with the Chalmers Manufacturing Company of Lima, Ohio, under the new name of the Chalmers Pump and Manufacturing Company, with general offices and works at Lima.

A. D. Stancliff has resigned as superintendent of the Western States Portland Cement Company, Independence, Kan., to accept a similar position with the Cuban Portland Cement Corporation of Havana, Cuba.

Frank G. Wheeler, until recently connected with the Miehle Printing Press and Manufacturing Company, Chicago, Ill., has become associated with the Chapman Engine Works, Marcellus, Mich.

ANNOUNCEMENTS

C. H. Stoddard has become consulting marine engineer for the Heiner Boiler Company.

Ray B. Whitman, formerly engaged in patent work in Chicago, has opened offices in New York, to engage in practice as a patent attorney and engineer, specializing on mechanical and marine inventions. Before entering the patent field, Mr. Whitman was a member of the firm of Whitman and Whitman, mechanical and electrical engineers of Chicago, and during the war was in shipbuilding work with the Emergency Fleet Corporation on the Great Lakes.

Hugh Pattison has accepted a position with the Westinghouse Electric and Manufacturing Company, New York.

Warren B. Hood, since receiving his discharge as Captain in the Ordnance Department, has become connected with the engineering department of the New York Shipbuilding Corporation, Camden, N. J.

P. C. Sanguinetti has assumed the direction of the research department of L. Bamberger and Company, Newark, N. J. He was affiliated, for several years, with Marwick, Mitchell, Peat and Company, public accountants and industrial engineers, and until recently was engaged in the cost accounting and production engineering field at various plants in the United States and Canada.

Lieut. Commander John L. Murrie, U. S. N. R. F., formerly of the New York Edison Company, who has been released from active duty in the government service, and Captain Edward F. McCrossin, U.S.A., announce the formation of a partnership under the firm name of

Murrie and Company, with offices in New York. The firm will conduct a general engineering practice, specializing in engineering, financial and operating reports, valuations and gas and electric rate cases.

William F. Walsh has accepted the position of representative of the Galena-Signal Oil Company, with headquarters in Chicago, Ill.

Earle W. Vinnedge, First Lieutenant, 7th U. S. Engineers Train, A. E. F., has been discharged from service and has become affiliated with the Worthington Pump and Machinery Corporation, Cincinnati, Ohio, in the capacity of sales engineer.

George C. Lewis has assumed the duties of manager of the Philadelphia office of Hersh and Brother. He was until recently assistant chief engineer of the company, at Allentown, Pa.

A. O. Hurxthal, Captain Ordnance Department, U. S. A., has received his discharge from service and has become associated with The Philadelphia Textile Machinery Company, Philadelphia, Pa.

F. W. Shumard, supervisor of the machine and small tools branch of the Motor Transport Corps, Maintenance Division, Washington, D. C., has left the Government service and is now superintendent of Arnold Hellmuth Manufacturing Company, Brooklyn, N. Y.

Major Paul Doty, Mem. Am. Soc. M. E., of the general staff, United States Army, came home to St. Paul on May 31 on a brief leave of absence after 21 months in the service. Major Doty was vice-president and general manager of the St. Paul Gas Light Company until September, 1917, when he was assigned to take charge of the utilities at Camp Grant, Ill., and became in effect "city manager" of that military city, directing the operation and maintenance of the large steam heating, electric lighting, water and sewage plants. He was later called to Washington and given general charge of the administration of the utilities of all camps and cantonments. In September, 1918, he was assigned to duty with the general staff.

Frank H. Clark has opened an office in New York, as consulting and inspecting engineer, and will handle reports on railway conditions and operations, plans and specifications for railway equipment and for shop and power-plant facilities and inspection of equipment and materials. Mr. Clark was formerly general superintendent of motive power of the B. and O. R. R., Baltimore, Md.

APPOINTMENTS

Ernest Gledhill has been appointed engineer representing the equipment division of the salvage sales section of the Remington Arms Union Metallic Cartridge Company, Bridgeport, Conn.

A. B. Russell, formerly works manager of the Ilion, N. Y. plant of Library Bureau, has been appointed general production manager in charge of the various manufacturing activities of Library Bureau.

William Knight, formerly assistant mechanical engineer of the Crocker-Wheeler Company, Ampere, N. J., and during the war a first lieutenant in the Air Service, U. S. A., has recently been appointed technical assistant to the National Advisory Committee for Aeronautics in Europe, with headquarters in Paris, France.

W. C. Tyler, formerly district manager at the New York office of the Poole Engineering and Machine Company, of Baltimore, Md., has been appointed general sales manager in charge of all the selling activities of the country. The general sales office of the company has been removed from Baltimore to New York.

H. R. Trotter, formerly chief engineer of the S K F Ball Bearing Company, has been appointed chief engineer of the S K F Industries, Inc., New York. The S K F Industries, Inc., has recently been organized to supervise the sales and engineering activities of the Hess-Bright Manufacturing Company, the Atlas Ball Company, the S K F Engineering Laboratories and the S K F Ball Bearing Company.

LIBRARY NOTES AND BOOK REVIEWS

The American Machinist Shop Note Book. A Collection of Articles Written for the *American Machinist* by Practical Men, Covering a Wide Variety of Machine Shop Activities and Giving the Solution of Problems that have Arisen in Machine Shops the World Over. Compiled by E. A. Suverkrop. First edition. Published by *American Machinist*, McGraw-Hill Book Co., Inc., sole selling agents, New York, 1919. Cloth, 6 x 9 in., 301 pp. 223 illus., $2.

Contents: Drafting and Design, Patterns and Foundry, Forge Shop, Hardening and Tempering, Drilling Machine, Engine Lathe, the Milling Machine, Planer and Shaper, Tool Making, Die and Press Work, Gages, Grinding, Boring, Gearing, Screw Machine, Shop Tools, Appliances and Expedients.

A collection of methods for dealing with difficult or unusual machine-shop jobs, compiled from the periodical mentioned, and classified under the above headings to facilitate ready reference. The articles show methods that have been successful and are suggestive to the machinist faced by similar difficulties.

Cutting Central Station Costs. Ways by which Central Station Managers, Operating Engineers and Sales Managers are Meeting High Costs. Compiled by S. B. Williams. First edition. Published by *Electrical World*, McGraw-Hill Book Co., Inc., sole selling agents, New York. 1919. Cloth, 6 x 9 in., 322 pp., illus. $2.

The commercial editor of the *Electrical World* has here collected the material contributed to that journal during the last nine months of the war, explaining methods adopted by various central stations. Economies in boiler and generating rooms, line construction, distribution methods, substation practice, commercial practice and administrative plans are discussed.

Efficient Railway Operation. By Henry S. Haines. The Macmillan Co., New York, 1919. Cloth, 6 x 9 in., 709 pp., tables, $4.50.

This volume is a description of the progressive development of efficiency in the operation of the railway system in the United States, as compared with similar progress in other countries; for the use of students, railway employees and general readers. Railway operation as distinguished from administration is the subject of the book; matters of finance, rates and labor questions are therefore not included. A bibliography and extensive statistical tables are given in the appendices.

Electricity and Magnetism for Engineers. Part II. Electrostatics and Alternating Currents. By Harold Pender. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 221 pp., 172 illus., $2.

Gives from an engineering point of view, a description of the more important effects commonly described as electrical and magnetic phenomena, and the application of these laws to some of the simpler problems which arise in connection with the generation, transmission and utilization of electric currents. Intended for college instruction.

Handbook for Highway Engineers. Containing Information Ordinarily Used in the Design and Construction of Rural Highways. By Wilson G. Harger and Edmund A. Bonney. Third edition, entirely revised. McGraw-Hill Book Co., New York, 1919. Flexible cloth, 4 x 7 in., 986 pp., illus., tables, 1 map, $4.

This handbook is a compact volume, presenting in convenient form the information ordinarily required in the field and office practice of road design and construction, and is planned to meet the requirements of both experienced and inexperienced road men. In the present edition, approximately 350 pages of new material have been incorporated, covering mountain-road location and design, camp equipment, medical notes, photography, selected soil and gravel treatment of moderate-traffic roads and the recent development of hard-surface roads.

The Nomon. By Horace G. Deming. Miles and Parris, Champaign, Ill. 1918. General edition, $1.60 postpaid; Chemists edition, $1.60 postpaid; Sugar Technologists' edition, $1.60 postpaid.

The Nomon is a calculating chart, based on a new mathematical principle, that will multiply, divide, square and cube numbers, and extract square and cube roots, to four figures, with an average error of one part in four or five thousand. It is cheap and portable, more accurate in many cases than the slide rule and

quicker than the calculating machine. A particular advantage is the ease with which it solves special formulas of complex types. Any function of a single variable, such as $ax + b$ or $ax^2 + bx + c$, may be multiplied or used as a divisor as if it were a simple variable. An instruction manual accompanies the chart.

TRAINING FOR THE ELECTRIC RAILWAY BUSINESS. Written under the supervision of T. E. Mitten by B. B. Fairchild, Jr. J. B. Lippincott Co., Philadelphia, 1919. Cloth 5 x 8 in., 155 pp., 9 pl., 3 charts, $1.50.

Explains in non-technical language the business side of electric railroading, and gives an insight into the requirements, the opportunities and the training involved in the several departments. The various engineering and transportation problems are taken up and the recruiting and management of the army of laborers needed thoroughly discussed.

THE TURNOVER OF FACTORY LABOR. By Sumner H. Slichter, with an introduction by John R. Commons. D. Appleton & Co., New York, 1919. Cloth, 5 x 8 in., 460 pp., tables, $3.

Contents: General Analysis of the Turnover, the Cost of the Turnover, the Causes of the Turnover and Methods of Reducing the Turnover. The author intends his volume as a comprehensive study of methods of handling men, to supplement existing books on works management. It is founded on personal experience in large industrial plants, visits to factories, talks with employers and working men, schedules and questionnaires. As the study was begun in 1913 and most of the data were collected before the acute situation in 1916, the discussion is from the standpoint in peace times. The book deals with manual laborers generally, except out-of-door seasonal workers.

TRAUTWINE. The Civil Engineer's Pocket-Book. By John C. Trautwine. Revised by John C. Trautwine, Jr., and John C. Trautwine, 3d. Twentieth edition. Trautwine Co., Philadelphia, 1919. Flexible cloth, 4 x 7 in., 1528 pp., illus., tables, $6.

The present volume represents the fourth extensive revision of this well-known work of reference since its original appearance in 1872, and the first since the nineteenth edition as published in 1909. The present edition contains 271 more pages than the preceding one. In its preparation about 400 pages of material have been inserted, relating principally to matters connected with railways, on which subject about 250 pages of new matter have been added. Besides this inclusion of new data, the work has been revised and brought up to date throughout.

MARINE INSURANCE. Its Principles and Practice. By William D. Winter. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 8 in., 433 pp., $3.50.

In this treatise, the writer presents a thorough, simple exposition on marine insurance; suited to the needs of shipping men, merchants and others who require a general knowledge of the subject. Based on a course of lectures given at New York University.

PRACTICAL SHELL FORGING. And the Plastic Deformation of Steel and Its Heat Treatment. By Clifford O. Bower. Longmans, Green & Co., New York, 1919. Cloth, 6 x 10 in., 279 pp., 152 illus., 4 pl., 17 tables, $10.50.

This volume, by an experienced British forge master, is a detailed account of the processes of shell manufacture in which particular attention is given to the laws governing the plastic deformation of steel at high temperatures and the variations in its physical character to be obtained by thermal treatment. It will be useful indirectly, the author hopes, to all persons engaged in the manufacture of hydraulic forgings.

Accessions to the Library

AERONAUTICS IN THE UNITED STATES. By George Owen Squier. *1918.* Gift of author.

AMERICAN ENGINEERING STANDARDS COMMITTEE. Constitution and rules of procedure. *New York.* Gift of Committee.

THE CHEMISTS' POCKET MANUAL. By Richard K. Meade. 3d edit. Purchase.

THE DECLARATION OF THE RIGHTS AND DUTIES OF NATIONS ADOPTED BY THE AMERICAN INSTITUTE OF INTERNATIONAL LAW. By Hon. Elihu Root. *Washington, D. C., 1916.* Gift of Carnegie Endowment for International Peace.

THE DELAMETER IRON WORKS—THE CRADLE OF THE MODERN NAVY. A bit of forgotten Greenwich Village history. By H. F. J. Porter. Gift of the author.

DICTIONNAIRE TECHNIQUE DE L'AVIATION. By John Lyeett, Engineer. *Paris, 1918.* Purchase.

DRAWINGS OF OLD PENNSYLVANIA RAILROAD CARS. 26 plates. Gift of Geo. L. Fowler.

EFFICIENCY OF NATURAL GAS AT LOW PRESSURES. Abst. of testimony of Samuel S. Wyer before the Corporation Commission of Oklahoma, Feb. 4, 1919. Printed by Empire Gas & Fuel Co., Kansas City, Mo.

ELECTRIC SMELTING OF DOMESTIC MANGANESE ORES. By H. W. Gillett and C. E. Williams. Gift of the Manchester Steam Users' Association.

ENGINEERING DIRECTORY. No. 65, October, 1918. *London.* Gift from *Engineering.*

ENGINEERING INDEX ANNUAL, THE. 1918. *New York, 1919.*

ENGINEERING SOCIETY OF CHINA. Proceedings and Report of the Council. 1917-18. *Shanghai.* Purchase.

ENGINEMAN'S MANUAL—RICHMOND COMPOUND LOCOMOTIVES. Gift of George F. Fowler.

FEDERAL TAX LAWS AFFECTING INDIVIDUALS, PARTNERSHIPS AND CORPORATIONS. Practical questions and answers. Irving Trust Co. *New York, 1919.* Gift.

FIELD SANITATION. By C. G. Moor and E. A. Cooper. *London, 1918.* Purchase.

FUELS OF WESTERN CANADA AND THEIR EFFICIENT UTILIZATION. Jas. White. Commission of Conservation of Canada. *Ottawa, 1918.* Gift of author.

GASES USED IN WARFARE. By D. D. Berolzheimer. Reprint from Jour. Ind. & Engng. Chem. Vol. 2, No. 3, p. 256. March, 1919. Gift of author.

GAUGES AT A GLANCE. Fourth edition. By Thomas Taylor. *New York and London, 1918.* Purchase.

GOVERNMENT OWNERSHIP OF PUBLIC UTILITIES IN THE UNITED STATES. By Leon Cammen. *New York, 1919.* Gift of author.

HANDBOOK ON EMPLOYMENT MANAGEMENT IN THE SHIPYARD. Special Bulletin, Labor Loss. U. S. Shipping Board Emergency Fleet Corporation. *Philadelphia, 1918.* Gift.

HIGH EXPLOSIVES. By Capt. E. de W. S. Colver. *London, 1918.* Purchase.

A HISTORY OF THE BESSEMER MANUFACTURE IN AMERICA. The Evolution of American Rolling Mills. By Robert W. Hunt. Reprint. Gift of author.

HOURS AND HEALTH OF WOMEN WORKERS. Report of Illinois Industrial Survey. Dec., 1918. Gift of Louis L. Emmerson.

HUMANIZING INDUSTRY. By Irving Fisher. *1919.* Reprint. Gift of author.

THE HYDROGENATION OF OILS. Catalyzers and catalysis and the generation of hydrogen and oxygen. By Carleton Ellis. Second edition. *New York, 1919.* Purchase.

I FENOMENI ELETTRO-ATOMICI SOTTO L'AZIONE DEL MAGNETISMO. By Augusto Righi. *Bologna, 1919.* Purchase.

INDUSTRIAL ARTS INDEX. 1918, 3 vols. Purchase.

INFLUENCE OF THE GREAT WAR UPON SHIPPING. By J. Russell Smith. Preliminary Economic Studies of the War, edited by David Kingley. No. 9. *New York, 1919.* Gift.

QUICKSILVER RESOURCES OF CALIFORNIA. Bulletin 78. California State Mining Bureau. *1918.* Purchase.

RAILWAY STATISTICS OF THE UNITED STATES OF AMERICA—FOR YEAR ENDED DEC. 31, 1917. 15th year. By Slason Thompson. Bureau of Railway News and Statistics. *Chicago, Ill.* Gift of Slason Thompson.

THE RECOVERY AND RE-MANUFACTURE OF WASTE PAPER. By James Strachan. *Aberdeen, 1918.* Purchase.

REFRACTORY MATERIALS AS A FIELD FOR RESEARCH. A survey of the scientific aspects of the subject. By Edw. W. Washburn. Reprint from the Jour. of the Amer. Ceremic Soc., vol. 2, no. 1, Jan., *1919.*

THE RELATIVE DESIRABILITY OF SHIPS OPERATING IN FOUR TRADE ROUTES. U. S. Shipping Board, Washington, D. C. Division of Planning and Statistics. *Feb. 28, 1919.* Gift of Henry V. R. Scheel.

RELATIVE MERITS OF CAST-IRON, WROUGHT-IRON AND STEEL PIPE FOR HOUSE DRAINAGE PURPOSES. By Wm. P. Gerhard. *New York, 1918.* Gift of the author.

THE REPRODUCTION OF SOUND. By Henry Seymour. *London.* Purchase.

SHIP CONSTRUCTION AND CALCULATIONS. By George Nicol. *Glasgow and London, 1918* Purchase.

TAXATION OF FOREST LANDS IN WISCONSIN, THE By Alfred K. Chittenden, Forest Examiner and Harry Irion, Forest Service. Sept. 1910 Gift of Geo. F. Fowler.

TRAIN BRAKES AND THE MECHANICAL PRINCIPLE WHICH CONTROL THEIR CONSTRUCTION, WIT SPECIAL REFERENCE TO LOCOMOTIVE BRAKES The Beals Railway Brake Company. Nov. 1 1888. Gift of Geo. F. Fowler.

THE TRANSACTIONS OF THE CANADIAN MININ INSTITUTE. Vol. 21. *Montreal, Quebec, 19* Purchase.

TUNNEL CONSTRUCTION — AFFIDAVIT OF DANI E. MORAN. Equity Suit in United States D trict Court—Duncan D. McBean, Complainar vs. The City of New York. vols. I, II, I Gift of Arthur McMullen.

THE ENGINEERING INDEX

Published Monthly by The American Society of Mechanical Engineers

The Engineering Index was Founded in 1884 *by the Association of Engineering Societies; Published from* 1895 *to* 1919 *by The Engineering Magazine Company; and Acquired January* 1919 *by The American Society of Mechanical Engineers*

THE following pages form a descriptive Index to articles on engineering and related subjects in current periodicals. In its preparation the Society's engineering staff regularly examines all of the technical journals and society publications received by the Engineering Societies Library, which form one of the greatest and most complete collections of scientific periodicals in the world, comprising upward of 1100 distinct publications in some ten languages. Cross-references are freely introduced in the Index, and in all cases where the titles of articles are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC COPIES OF ARTICLES LISTED

THE Society is prepared to supply photostatic copies (white printing on brown background) of any of the articles listed. Copies of the periodicals themselves, or clippings of articles, cannot be supplied.

Price of each print (up to 11 x 14 in. in size), 25 cents plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Those holding coupon books for clippings formerly issued by The Engineering Magazine Company may use the coupons in payment for photostatic prints. In ordering, state plainly

(1) Page number of Index on which item appears
(2) Title of article
(3) Name of periodical.

Orders should be sent to

Harrison W. Craver, *Director,*
Engineering Societies Library,
29 West 39th Street, New York City.

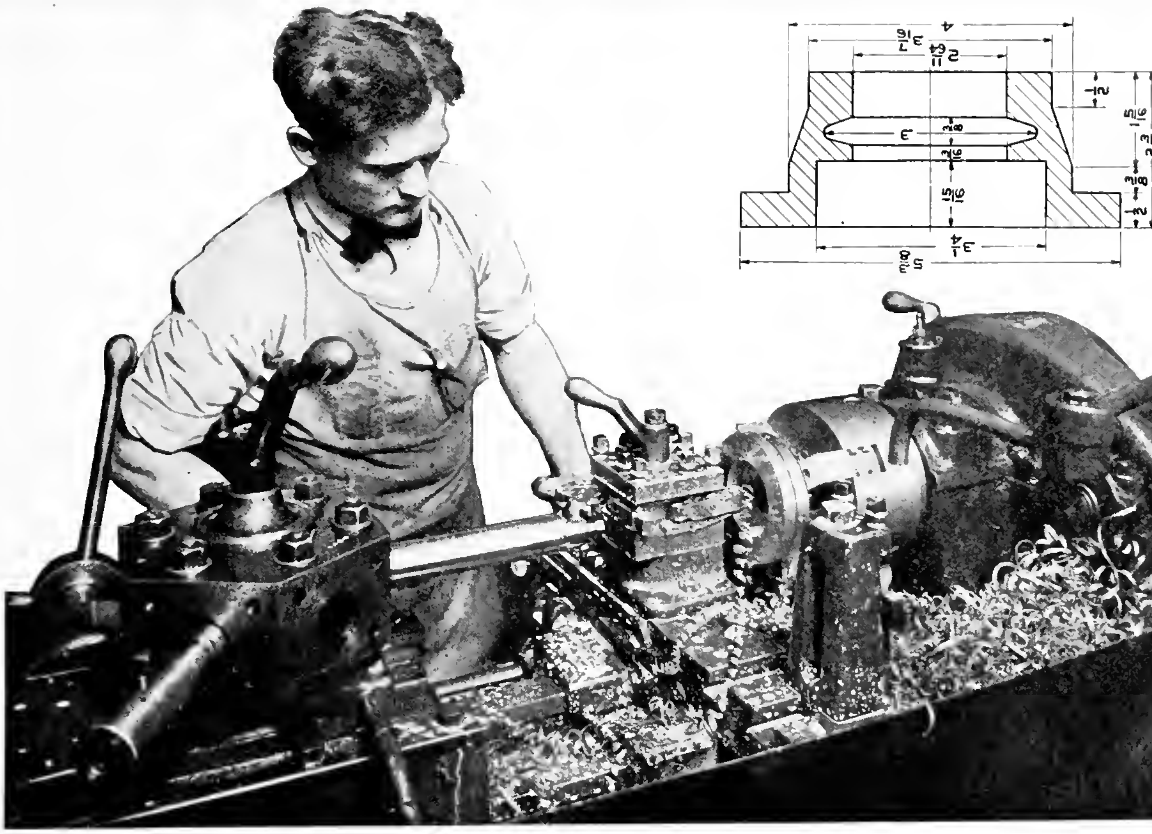
LIST OF TOPICS IN THE ENGINEERING INDEX

JULY, 1919



Value of the Square Turret

THIS shows the amount of material removed and how well the many operations on these tough power sprocket clutches were finished on the No. 4 Universal Screw Machine. The hexagon turret was used only for boring. The square turret, loaded to capacity with cutters, did the rest with the aid of its eight power cross and longitudinal feeds.

For Work Too Complicated for Ordinary Screw Machines

The special features of the No. 4 Universal (in this case the unusual use for the square turret) adapt them to a wide range of work too complicated for ordinary screw machines or turret lathes

SEND FOR DETAILS
Turret Lathes and Screw Machines
from 5/8 in. x 4 in. to 4½ in. x 44 in., Maximum Swing 21½ in.

Mechanical Engineering

CORROSION

Electrolytic Theory of Corrosion

The Effect of Air and Water on Materials Used in Engineering Work. H. E. Yerbury. Electrical Review, vol. 84, no. 2161, Apr. 25, 1919, pp. 484-486. Writer favors electrolytic theory of corrosion and quotes instances which, in his estimation, confirm it.

Rustproofing

Metallic Coating for Rust Proofing Iron and Steel—I. Henry S. Rawdon, M. A. Grossman and A. N. Finn. Chem. & Metallurgical Eng., vol. 20, no. 9, May 1, 1919, pp. 458-464, 1 fig. Recommendations in regard to rust-proofing metal coatings, with discussion of comparative values of different methods especially of zinc.

Wire Rope

The Internal Corrosion of Cables. Wm. Fleet Robertson. Min. & Sci. Press, vol. 118, no. 18, May 3, 1919, pp. 589-591, 1 fig. Lack of internal lubrication is believed to have been cause of rope failure at Nanaimo, B. C., Colliery, which resulted in 16 instant deaths.

See also MARINE ENGINEERING, Auxiliary Machinery (Propellers).

FOUNDRIES

Aluminum Casting

Progress in Aluminum Casting. Metal Indus., vol. 17, no. 5, May 1919, pp. 211-213, 4 figs. McAdamite Aluminum Co.'s plant at Detroit said to have been erected with a view to have all operations go in continuous process from unloading of raw material to shipment of finished castings.

Brass Foundry

Materials and Chemicals Used in Brass Foundry Practice—VI. Charles Vickers. Brass World, vol. 15, no. 5, May 1919, pp. 139-141, 1 fig. Patented processes for producing phosphorus and its compounds. Serial dealing with history, properties, appearance, physiological action and commercial use of substances commonly used in brass founding.

Chain, Steel Anchor

Molding and Casting Heavy Steel Anchor Chain. Foundry, vol. 47, no. 320, Apr. 1, 1919, pp. 141-147, 13 figs. Development of process; method of assembling individual links in molds preparatory to pouring connecting links.

Crucibles

Behavior Under Brass Foundry Practice of Crucibles Containing Ceylon, Canadian and Alabama Graphites. R. T. Stull. Jl. Am. Ceramic Soc., vol. 2, no. 3, Mar. 1919, pp. 208-226, 2 figs. Experimental research showed that substitution of Canadian graphite up to 25 per cent for Ceylon decreased life of crucible; the crucibles containing 100 per cent Canadian graphite are nearly as good as those containing 25 per cent Canadian and 75 per cent Ceylon, but that substitution of Alabama flake graphite for Ceylon improved crucible's life.

Die Castings

Die Castings and Their Application to the War Program. Charles Pack. Automotive Eng., vol. 4, no. 4, Apr. 1919, pp. 183-186, 9 figs. Development of industry, early machines and their work. Attempts to avoid blowholes and influence of this on machines. War castings produced.

Job Work

Diversified Output at Canton Plant. Foundry, vol. 47, no. 6, May 1, 1919, pp. 243-250, 11 figs. Organization of large foundry which produces castings weighing from 1 lb. up to 100 tons.

Pump Casing

How a Large Pump Casing was Molded and Cast. Foundry, vol. 47, no. 7, May 15, 1919, pp. 281-283, 6 figs. Green-sand, skin-dried mold used with dry-sand core made on floor with the mold and dried in an oven.

Research

Application of Physical and Chemical Research to Cast Iron Foundry Practice (Exemples d'utilisation dans la pratique industrielle de la fonderie de fonte des résultats d'essais physiques et chimiques). J. Seigle. Bulletin et comptes rendus mensuels de la Société de l'Industrie Minérale, series 5, vol. 15, first issue of 1919, pp. 127-143, 13 figs. Technical discussion. Reference is made to investigations outlined in Industrie Minérale, second issue, 1918.

Sand Blast

Application of the Sand-Blast. H. D. Gates. Iron Age, vol. 103, no. 18, May 1, 1919, pp. 1135-1138, 5 figs, also Metal Trades, vol. 10, no. 5, May 1919, pp. 203-206, 4 figs, second article. Relationship between air pressure and abrasion. Sand-blast air drier adopted by Emergency Fleet Corp. Barrel, cabinet and table types of sand-blast equipment. Paper read before Newark Foundrymen's Assn.

Sand Molding

Ferruginous and Other Bonds in Molding Sands. P. G. H. Boswell. Foundry, vol. 47, no. 320, Apr. 1, 1919, pp. 148-150. European practice; mechanical and chemical analyses of English sands.

Ship Work

Making Castings Used in Ship Construction—II. Ben Shaw and James Edgar. Foundry, vol. 47, no. 6-7, May 1-15, 1919, pp. 251-255 and 297-300, 41 figs. Details of making rudder pattern by two methods and description of core-box construction. Ramming, setting and pouring basins.

Steel Castings

Making Steel Castings by the Best Steel Casting Company. Metal Trades, vol. 10, no. 5, May 1919, pp. 199-201, 5 figs. Lebanon pig iron, to which is added a considerable amount of low-phosphorus and low-carbon plate scrap, is used.

Foundry With Diversified Output. Iron Trade Rev., vol. 64, no. 19, May 8, 1919, pp. 1211-1217, 11 figs. Facilities created for large scale production of steel castings.

Wheels, Truck

Making Quad Wheels in a Tractor Foundry. Foundry, vol. 47, no. 320, Apr. 1, 1919, pp. 157-161, 8 figs. Operation involved in manufacture of four-wheel drive army trucks.

See also MARINE ENGINEERING, Yards (Castings).

FUELS AND FIRING

Coal Storage

The Storage of Coal. Eugene McAuliffe. Ry. Rev., vol. 64, no. 20, May 17, 1919, pp. 712-714, 1 fig. Concerning methods of unloading. Fuel Conservation Circular no. 17 of U. S. Fuel Administration.

Gas and Oil Fuels

See Producer Gas, page 12a; items under INDUSTRIAL TECHNOLOGY; and Oil and Gas, under MINING ENGINEERING.

Peat

The Future of Peat as a Fuel—I. J. B. C. Kershaw. Coal Age, vol. 15, no. 20, May 15, 1919, pp. 898-901, 6 figs. Peat being considered as more widely distributed throughout the world than were the original beds of coal-forming materials, its utilization is considered advisable, and reference made to uses in various countries of drying and briquetting it. (To be continued.)

Pulverized Fuel

Instructions for Safe Use of Pulverized Fuel. Engineer, vol. 127, no. 3304, Apr. 25, 1919, pp. 398-399. Prepared by Pulverized Fuel Equipment Co., N. Y.

Use of Pulverized Coal, With Special Reference to Its Application in Metallurgy. L. C. Harvey. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 8, 73 pp., 29 figs., also, slightly abridged, Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 590-599, 17 figs., and Colliery Guardian, vol. 117, no. 3045, May 9, 1919, pp. 1081-1085, 5 figs. (To be continued.) Examples of installations, details of burners, curves showing results of operation and operating costs, and bibliography of recent articles on powdered coal.

Pulverized Coal and Its Bearing on the Fuel Situation. H. G. Barnhurst. Am. Fertilizer, vol. 50, no. 9, Apr. 26, 1919, pp. 48-49. Cost of pulverized coal equipment per boiler per rated boiler hp.

See also RAILROAD ENGINEERING, Operation and Management (Fuel Conservation, Oil Fuel Trials); MINING ENGINEERING, Coal and Coke; ELECTRICAL ENGINEERING, Generating Stations (Peat-Fired Central Stations); MECHANICAL ENGINEERING, Power Plants (Pulverized Coal Plants.)

FURNACES

See ELECTRICAL ENGINEERING, Furnaces; MECHANICAL ENGINEERING, Heat-Treating (Furnaces.)

GAGES

Errors

On Some Principles of Manufacturing Interchangeable Articles to Limit Gauges. G. Gerald Stoney and S. Lees. Engineering, vol. 107, no. 2777, Mar. 21, 1919, pp. 361-362, 1 fig. Analytical derivation of error, based on Gauss' theoretical law of distribution of errors.

Flush-Pin Sliding Bar

Flush-Pin Sliding Bar and Hole Gauges. Machy. (Lond.), vol. 14, no. 345, May 8, 1919, pp. 163-171, 34 figs. Principles involved and procedure followed by Pratt & Whitney Co. in developing gauging systems for interchangeable manufacture. (Fourth article.)

Johansson Gages

The Use of Gage Blocks in Inspection. Ernst Mentor. Inspector, vol. 1, no. 1, June 1919, pp. 5-11, 37 figs. Development and uses of Johansson gages.

Optical Testing of Flat Surfaces

U. S. Bureau of Standards' Method of Measuring in Millionths. H. S. Bean. Inspector, vol. 1, no. 1, June 1919, pp. 12-13 & 21, 3 figs. Optical testing of flat surfaces and comparison of size standards.

Tolerances

Notes on the System of Tolerance in Mechnical Construction (Remarques sur le système des tolérance dans les constructions mécaniques). Génie Civil, vol. 74, no. 18, May 3, 1919, pp. 353-355, 10 figs. Technical study of limitations, based on principles of symmetrical and unsymmetrical systems.

GAS ENGINEERING

Centralization of Gas Supply

Centralization in Public Gas Supply. J. H. Brearley. Gas World, vol. 70, no. 1812, Apr. 12, 1919, pp. 274-276, 1 fig. Discusses objections generally offered against centralization of gas supply. As example a scheme for Huddersfield (town adjacent to a number of small gas undertakings) is proposed.

Doors, Self-Sealing

Fifteen Ovens of Michigan Light Company at Kalamazoo Have Capacity of 1,250,000 Cu. Ft. of High-Grade Gas per Day. Louis Resnick. Am. Gas Eng. Jl., vol. 110, no. 18, May 3, 1919, pp. 373-380, 6 figs. Salient features of installation is self-sealing doors which are said to have given satisfaction throughout six months of operation.

Gas from Wood and Peat

Manufacture of Gas from Wood and Peat. Gas Jl., vol. 146, no. 2917, Aprl. 8, 1919, pp. 83-84. Swiss experience in commercial practice.

Gas Production, New Method of

New System of Gas Production (Et nyt system for gasfremfremstilling). Teknisk Ukeblad, vol. 66, no. 12, Mar. 21, 1919, pp. 174-175. Combination of present system of externally fixed retorts and water-gas producers, but combustion takes place inside retorts and is arrested when coal is changed to coke.

Water Gas

Water-Gas Operating Methods with Central District Bituminous Coals as Generator Fuel—Notes on Experiments on a Commercial Scale. W. A. Dunkley and W. W. Odell. State of Ill., Dept. Registration & Education, Div. State Geol. Survey, Coöperative Min. Ser., bul. 24, 1919, 27 pp. Summary of experiments on commercial scale.

HANDLING OF MATERIALS

Belt Conveyors

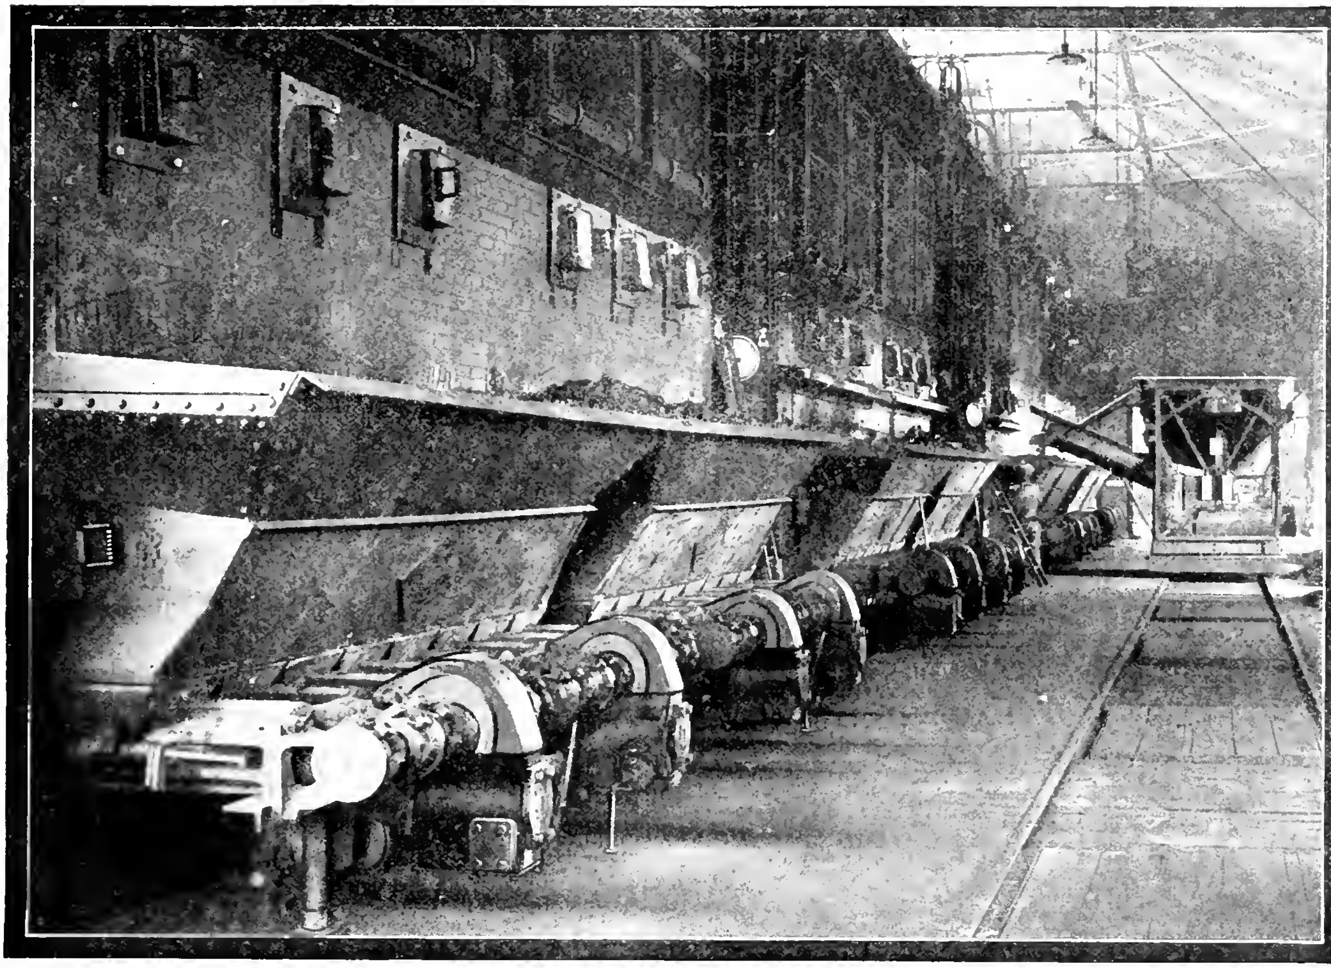
Coal and Ash Handling Equipment—III Robert June. Refrig. World, vol. 54, no. 5 May 1919, pp. 25-27, 4 figs. Requirements fo installing continuous belt conveyors.

Coal Tipples

New Coal Tipple at a Virginia Operation, C Sharon. Coal Age, vol. 15, no. 18, May 1 pp. 796-798, 7 figs. Described as compact an embodying means for obtaining various grade or mixtures of grades.

Iron and Steel Works

Some Notes on the Handling of Raw Ma terials for Iron and Steel Works. W. W. M Gosh. Jl. West of Scotland Iron & Ste Inst., vol. 26, parts 4 & 5, sessions 1918-191 January 1919, pp. 68-74 and (discussions) p 74-78, 18 figs. on supp. plates, also Iron Coal Trades Rev., vol. 98, no. 2670, May 1919, p. 532. Illustrating practice in vario Scottish plants.



300% Continuous Rating with Plenty of Reserve Capacity

High capacity is not only possible but highly economical. 300% continuous rating is EASY operation for the RILEY STOKERS at the Columbus Railway, Power & Light Company.

24-hour tests conducted on eight-retort stokers operating above 300% with 10,775 B. T. U. coal gave the following results:

Stoker & Boiler	Duration	% Rating Developed	% Efficiency with economizer
No. 3	24 Hours	305	72.2
No. 4	24 Hours	302	76.4

If your load calls for 300% of continuous rating or 400-500% of rating during peaks—write us.

Our engineers are ready to co-operate; possibly they can save you much time, money, men and material.

Our catalog explains the *live grate surface* and the *continuous, automatic, ash discharge*—two essentials for high efficiency and capacity.

SANFORD RILEY STOKER COMPANY ∴ WORCESTER, MASS.

British Licensees: Erith's Engineering Co., Ltd., London - - - French Licensees: Erith, Leroy & Cie., Paris

TRADE MARK Rx REGISTERED

RILEY UNDERFEED STOKERS

TRADE MARK Rx REGISTERED

Ore Handling

Automatic Ore Handling Plant. Iron & Coal Trades Rev., vol. 98, no. 2670, May 2, 1919, pp. 534-536, 15 figs., partly on supp. plate. Design for unloading railway wagons as they come into works with iron ore at a rate of 300 tons per hour.

Telpherage

Power Plant Management; Coal and Ash Handling—III, Robt. June. Power House, vol. 12, no. 6, May 5, 1919, pp. 154-156, 4 figs, also Brick & Clay Rec., vol. 54, no. 9, May 6, 1919, pp. 778-779, 3 figs. (Third article). Installation of Jeffrey telpherage system at plant of Scioto Traction Co. Contents are discharged directly into coal pit from which coal is removed by grab bucket and transferred either to overhead bunker or to storage.

HEAT-TREATING

Carburization at Low Temperatures

The Carburization of Iron at Low Temperatures, Andrew McCance. Iron & Steel Inst., Ann. Meet., May 8 & 9, 1919, no. 12, 5 pp., 1 fig. Consideration of variation of equilibrium conditions with temperature leads to assertion that above 550 deg. cent. ferrous oxide is more easily converted into carbide than pure iron.

Case-Hardening

Improvements in the Case-Hardening Process, D. Hanson and J. E. Hurst. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 7, 19 pp., 6 figs., also Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 573-575. Theoretical and experimental research leads to assertion that ordinary methods of case-hardening at or above 900 deg. cent. tend to formation of hypereutectoid layer in the case, which is a frequent source of flaking and grinding cracks.

Furnaces

Metallurgical Furnaces—II. Adolph Bregman. Metal Indus., vol. 17, no. 5, May 1919, pp. 218-220, 5 figs. Advises that in the design and operation of heat-treating plants, efficiency of furnace from standpoint of finished product be estimated from uniformity with which product is heated throughout its entire mass when heat chamber is filled to its full working capacity.

Low-Carbon Steel

Heat Treatment of Low-Carbon Steel, W. H. Wilkie. Jl. Am. Steel Treaters Soc., vol. 1, no. 6, Mar. 1919, pp. 194-206, 12 figs. Cautions against placing cold piece of steel into highly heated furnace, and recommends quenching piece with axis vertical in order to prevent excessive warping or cracks due to unequal contraction in cooling.

Men

Fundamental Principles to be Considered in the Heat Treatment of Steel, R. A. Hayard. Chem. & Metallurgical Eng., vol. 20, no. 10, May 15, 1919, pp. 519-523. Advises encouraging men to think about the work they are handling and exercising creative instinct whenever possible, and devolping sense of responsibility by allowing men to visualize their work by using charts and graphs.

Steel-Mill Practice

Relation of Steel Mill Practices to Subsequent Heat Treating, A. F. MacFarland. Jl. Am Steel Treaters Soc., vol. 1, no. 6, Mar. 1919, pp. 183-193, 10 figs. Quality of steel produced, and its ability to respond to heat treatment giving superior physical properties desired, said to depend entirely upon local conditions surrounding its manufacture.

HEATING AND VENTILATION

Central-Station Heating

Central Station Heating in Detroit, J. H. Walker. Mech. Eng., vol. 41, no. 6, June 1919, pp. 497-503, 8 figs. Complete utilization of heat ordinarily discharged to condensing water in central electric generating station for purpose of heating buildings is held responsible and difficulties in way of even its partial utilization are pointed out with particular reference to conditions existing in Detroit. Paper for Spring Meeting of A. S. M. E.

Equipment

Care of Heating and Ventilating Equipment—IX, Harold L. Alt. Power, vol. 49, no. 18, May 6, 1919, pp. 675-679, 9 figs. Several vapor systems are taken up and their characteristics explained, together with information regarding some of the special apparatus used with each.

Theater Ventilation

Theater Ventilation From a Health and Business Standpoint, E. Vernon Hill. Domestic Eng., vol. 87, no. 6, May 10, 1919, pp. 237-239 and 270. Mechanical equipment is judged necessary, and its installation profitable to contractor and owner.

HOISTING AND CONVEYING

Compressed-Air Hoisting Engine

Compressed Air Hoisting Engine for a Mine in India. Engineer, vol. 127, no. 3302, Apr. 11, 1919, pp. 356 & 363, 4 figs. Cylinders are 18 in. in diamater by 3-ft. stroke and work at pressure of 60 lb. per sq. in.

Conveyors, Portable

Cutting Conveying Costs in the Brick Plant. Brick and Clay Rec., vol. 54, no. 9, May 6, 1919, pp. 765-767, 6 figs. Installation of portable conveyor. Examples of its applications are illustrated.

Crane, Bridge, Transporters

Handling Devices in British Shell Shops—IV. Eng. & Indus. Management, vol. 1, no. 2, Apr. 24, 1919, pp. 349-355, 13 figs. Material is conveyed through shop by railways and two bridge crane transporters. (Concluded from p. 361.)

Cranes, Gantry

A New Way of Loading Ocean Freighters. Ry. Elec. Engr., vol. 10, no. 5, May 1919, pp. 153-156, 7 figs. Illustrating how electrically operated gantry cranes quickly transfer locomotives from cars to ship.

Elevator Control, Electromagnetic

Electro-Magnetic Electric Elevator Control, T. Schutter. Elec. Eng., vol. 52, no. 6, Dec. 1918, pp. 36-38, 4 figs. Otis elevator control.

Elevators, Mechanical

Mechanical Lifts—Past and Present, J. F. Robbins. Mech. Eng., vol. 41, no. 6, June 1919, pp. 507-512, 9 figs. A new type of lift described has the points of support of two counter-balancing loads so interconnected that movements of supporting elements of structure are synchronized and it is made impossible for supports to get out of level. Applicable to freight-car lifts, lift bridges, canal-lock lifts, etc.

Fordson Methods

Handling Parts in the Shop and on the Assembly Floor, J. Edward Schipper. Automotive Industries, vol. 40, no. 19, May 8, 1919, pp. 1009-1012, 5 figs. Conveying apparatus installed in tractor works of Henry Ford & Son plant.

Inclined Plane

Inclined Plane of the Union Mining Co., U. U. Carr. Coal Age, vol. 15, no. 19, May 8, 1919, pp. 856-857, 3 figs. Electrically driven hoist was installed in place of inclined-plane machine that proved inadequate to handle increased output.

Mechanical Handling Equipment

Seattle's Mechanical Handling Equipment, G. F. Nicholson. Pac. Mar. Rev., vol. 16, no. 5, May 1919, pp. 102-105, 4 figs. Consists partly of shear-leg derricks, gantry cranes, stiff-leg derricks, 12 miles of railway tracks and eight loading platforms; equipment is electrically operated.

Winding Equipment

An Electrically Driven Winding Equipment. Electrical Review, vol. 84, no. 2161, Apr. 25, 1919, pp. 460-461, 2 figs. Induction motor is geared to spur wheel on drum shaft, driving pinion being mounted on extension shaft supported by two bearings, connection to latter shaft being made through flexible coupling. Installed at Kilton Colliery in shaft 720 ft. deep.

HYDRAULIC MACHINERY

Big Chute Plant

Big Chute Generating Station, W. L. Amos. Can Engr., vol. 36, no. 19, May 8, 1919, pp. 436-438 4 figs. Evolution of present power plant at Big Chute on Severn river from 1909 to addition of four generating units in January 1919.

French Plant

Hydroelectric Plant of the Loire and Center Electric Co. at Ance (L'usine hydro-électrique de l'Ance de la Compagnie électrique de la Loire et du Centre), Jacques de Soucy. Revue Générale de l'Electricité, vol. 5, no. 18, May 3, 1919, pp. 659-670, 15 figs. Output is 30,000,000 kw-hr. per year. (To be continued.)

Governor, Hydraulic-Turbine

New Hydraulic Turbine Governor (Nouveau regulateur à action indirecte et à indication mixte), M. Barbillion and M. Cayere. Houille Blanche, vol. 18, no. 25-26, Jan.-Feb. 1919, pp. 23-25, 4 figs. Advantages claimed are: extra rapid regulation, disappearance of speed oscillations, easy setting, and sensitiveness.

Ice Troubles

Design of Hydro-Electric Plants for Combatting Ice Troubles, R. M. Wilson. Jl. Eng. Inst. Can., vol. 2, no. 5, May 1919, pp. 383-387 and (discussion) pp. 387-395, 2 figs. Classification and discussion of ice troubles. Remarks upon selection of site and design of head and tail-race channels with a view to eliminate trouble and damage both to the outside portion of development and to hydraulic equipment.

Water Hammer

Water Hammer in Conduits Made Up of Truncated Cones (Sur les coups de bélier dans les conduites de diamètre variable et formées de parties tronconiques), G. Guilliaumin. Comptes rendus des séances de l'Academie des Sciences, vol. 168, no. 14, Apr. 7, 1919, pp. 723-726. Analytical. Conclusion is reached that oscillation period is either smaller or greater than $2\ \theta = 4\ l/a$ according as conduit diverges or converges up the stream.

Pressures in Penstocks Caused by the Gradual Closing of Turbine Gates, Norman R. Gibson. Proc. Am. Soc. Civ. Engrs., Papers and discussions, vol. 45, no. 4, Apr. 1919, pp. 173-206, 9 figs. Determined from Professor Joukovsky's theory of maximum water hammer. Solution of problem by trial-and-error method is first given, and then formulæ are derived that cover governor time and relation between stroke and gate movement.

Western Canada Plant

The Plant of the Western Canada Power Company, F. C. Perkins. Power House, vol. 12, no. 6, May 5, 1919, pp. 145-146, 1 fig. Hydro-electric plant operating at 125-ft. head.

See also MECHANICAL ENGINEERING, *Pumps (Hydraulic Pumps.)*

INTERNAL-COMBUSTION ENGINES

Atmospheric Conditions

Atmospheric Conditions Affecting Power, A. Johnson. Automobile Engr., vol. 9, no. 123, Feb. 1919, pp. 37-38, 3 figs. Table for estimating probable power and consumption of engine at elevations above sea level. Mathematical reasoning on which it is based is included.

Diesel Engines

Diesel Engines Prove Economical at Lincoln, O. J. Shaw. Elec. Ry. Jl., vol. 53, no. 19, May 10, 1919, pp. 902-905, 9 figs., also Power, vol. 49, no. 19, May 13, 1919, pp. 734-736, 4 figs. Maintenance cost figures obtained at plant where three 350-kw. Diesel units have been in service for more than two years in combination with steam equipment.

War Developments in Marine Oil Engines. Mar. Eng. & Can. Merchant Service Guild Rev., vol. 9, no. 4, Apr. 1919, pp. 140-141, 3 figs. Schneider 2150-i.hp. submarine Diesel engine, as used in French navy.

Engine Experiments

Engine Experiments, L. H. Pomeroy. Automobile Engr., vol. 9, no. 123, Feb. 1919, pp. 44-50, 11 figs. Influence of valve area, revolution speed, and combustion chamber design upon horsepower and thermal efficiency. Experiments made by Vauxhall Motors, Ltd., upon two 4-cyl. engines identical in design, save in arrangement of valves, which were of side-by-side type in one engine and overhead in the other.

Gas Engines

Large Horizontal Gas Engines in Modern Industry, H. Pilling. Gas & Oil Power, vol. 14, no. 164, May 1, 1919, pp. 109-119. Their application and working. Paper read before Cleveland Instn. of Engrs.

Heavy-Duty Car Engine

New Golden, Belknap & Swartz Engine for Trucks. Commercial Vehicle, vol. 20, no. 8, May 15, 1919, pp. 32-33, 4 figs. Four-cylinder model, designed to handle low-grade fuel.

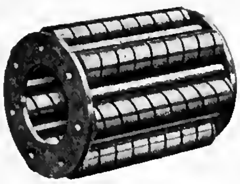
The 150 H. P. Ricardo Tank Engine, H. A. Hetherington. Automobile Engr., vol. 9, no. 126, May 1919, pp. 147-153, 27 figs. Cam details, governor arrangement, connecting-rod dismantling diagram, and table of general data. (Concluded.)

Oil Engine, Marine

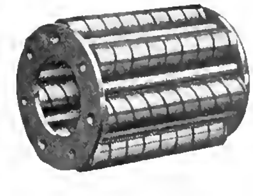
The Doxford Opposed-Piston Marine Oil Engine. Pac. Mar. Rev., vol. 16, no. 5, May 1919, pp. 106-108, 4 figs. Results obtained in tests on fuel economy and mechanical efficiency tried out under supervision of chief surveyor of Lloyds.

Rotary Engine

A Novel Rotary Engine. Autocar, vol. 42



ENGINEERING PRIDE



You, as an Engineer, feel a certain thrill in knowing that you are "utilizing the forces and materials of nature for the benefit of mankind."

You take pride in making things a little better than you found them—and in refining and improving existing designs—in producing better machines.

As an Engineer you owe it to yourself and to your profession to keep abreast of the times. Improvements in Engineering practice are constantly being made. Some of the principles learned at college must be revised in line with present day knowledge.

The modern trend in machine design is toward the universal use of anti-friction bearings. Are you still using the old style, power wasting, plain bearing? Are you penalizing a modern, carefully designed machine with old fashioned bearings?

Hyatt Roller Bearings are anti-friction bearings that merit the careful consideration of every thinking Engineer, because they are designed and constructed according to sound, modern engineering principles and form a logical part of modern machinery.

Send for our latest engineering data.

MOTOR BEARINGS DIVISION

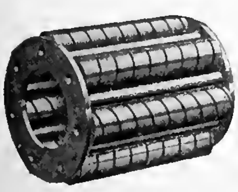
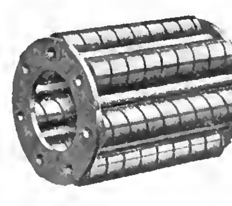
TRACTOR BEARINGS DIVISION
CHICAGO, ILL.



Manufacturers of Bearings for Mine Cars, Ore Cars, Steel Mill Cars, Roller Tables, Trolleys, Cranes, Hoists, Machine Tools, Line Shafts, Countershafts, Concrete Machinery, Textile Machinery, Conveyors, Lift Trucks, Industrial Trucks, Railway Service Cars, Storage Battery Locomotives, etc.



no. 1228, Apr. 1919, pp. 572-573, 2 figs. Power controlled by varying mass of charge and combustion space in invention of P. H. Gergasse, Sussex, England.

See also AERONAUTICS, Engines.

LUBRICATION

Submerged Governor Pins

Operation at Holtwood. Charles H. Bromley. Power, vol. 49, nos. 19 & 20, May 13 & 20, 1919, pp. 713-715, and pp. 770-776, 24 figs. Lubrication of submerged pins in governor operating mechanism. Record-keeping forms and follow-ups.

MACHINE ELEMENTS AND DESIGN

Ball Bearings

Ball Bearings and Haulage Economies. Arthur Hall. Iron & Coal Trade Rev., vol. 98, no. 2669, Apr. 25, 1919, p. 512, 2 figs. Test made at South African mines.

MACHINE SHOPS

Cylinder Grinding

Cylinder Grinding. Machy. (Lond.), vol. 14, no. 343, Apr. 24, 1919, pp. 93-99, 13 figs. Advantages of finishing cylinder bores by grinding; machines and auxiliary equipment used; practice in different plants manufacturing engines for automobiles and airplanes. (First article.)

Cylinder Machinery

Operations on the Liberty Motor Cylinders—II. H. A. Carhart. Am. Mach., vol. 50, no. 21, May 22, 1919, pp. 985-991, 14 figs. Information as to speeds, etc., in machining operations.

Jigs and Tools

Jigs, Tools, and Special Machines, with Their Relation to the Production of Standardised Parts. Herbert C. Armitage. Engineering, vol. 107, no. 2778, Mar. 28, 1919, pp. 402-406, 10 figs., also Eng. & Indus. Management, vol. 1, no. 10, Apr. 17, 1919, pp. 301-306, 11 figs. (2d article.) Advantages claimed are interchangeability of work, cheapening of production, ability to use less-skilled class of labor, elimination of fittings and introduction of assembling methods. (To be continued.)

Templets, Jigs and Fixtures. Joseph Horner. Engineering, vol. 107, nos. 2777 & 2781, Mar. 21 & Apr. 18, 1919, pp. 367-370 & 493-497, 39 figs. Fixtures for use on plain millers, made by Kempsmith Mfg. Co., Milwaukee, Wis. Multiple drilling machines constructed by Moline Tool Co., Moline, Ill. (Continuation of serial.)

Milling and Drilling Motor Parts

Machining a Six-Cylinder Motor—I & II. J. V. Hunter. Am. Mach., vol. 50, nos. 18 & 19, May 1 & 8, 1919, pp. 851-853 & 887-890, 17 figs. Milling and drilling operations followed by Falls Motor Corp. of Sheboygan Falls, Wis. Milling motor parts in multiple.

Threads, Metric

Metric Threads. Theodore Chaundy and T. H. Plummer. Engl. Mechanic & World of Sci., vol. 109, no. 2823, May 2, 1919, pp. 172-173. Rules for cutting them on English lathes. From Ministry of Munitions Jl.

Trays, Wrench Holders and Pans

Arranging Trays, Wrench Holders and Pans on Machine Tools. F. Scriber. Can. Machy., vol. 21, no. 20, May 15, 1919, pp. 487-489, 18 figs. Examples of various types and discussion of their advantages.

MACHINERY, METAL-WORKING

Cast Cutting Tools

Casting Cutting Tools from Crucible Steel. J. E. Johnson, Jr., Junior Foundry, vol. 47, no. 320, Apr. 1, 1919, pp. 162,164, 7 figs. Micro-photographs made by Davidson process.

Cylinder Boring and Reaming Tools

Cylinder Boring and Reaming Tools. Machy (Lond.), vol. 14, no. 342, Apr. 1919, pp. 61-68, 28 figs. Types and designs of cutter heads and reamers used for rough boring and reaming small engine cylinders.

Lathe Tools

Capstan Lathe Tools. I. E. W. Field and A. E. Simpson. Machy. (Lond.), vol. 14, no. 345, May 8, 1919, pp. 173-175, 10 figs. Deals with spring-collet or split-jaw type of chuck, particularly design of H. W. Ward & Co., Birmingham. Paper read before Coventry. Eng., Soc.

Some Fittings and Attachments to a 5-in. S. C. Lathe for Repetition Work. T. W. Averill. Model Engr & Elecn., vol. 40, no. 938, Apr. 17, 1919, pp. 275-282, 20 figs. Reduction gear and clutch for actuating lead screw to obtain self-acting sliding motion.

Lathes

The New Drummond Lathes. Machy. (Lond.), vol. 14, no. 345, May 8, 1919, pp. 153-158, 13 figs. Special reference is made to manner of testing, truth of fast headstock in relation to center axial line, relative height of center, cam action in chuck, cam action in lead screw and lead-screw pitch.

Machine Tools

Machine Tools. Alfred Herbert. Engineering, vol. 107, no. 2776, Mar. 14, 1919, pp. 355-358. Their development in recent years, with special reference to present tendencies to standardization. Paper before North East Coast Instn. of Engrs. & Shipbuilders.

Milling Machines

The Becker Model D-1 Vertical Milling Machine. Am. Mach., vol. 50, no. 18, May 1, 1919, pp. 825-827, 3 figs. Designed to permit pieces of work weighing up to 10 tons being carried and machined on work table.

The New Cincinnati No. 5, High Power Milling Machine. John H. Van Deventer. Am. Mach., vol. 50, no. 21, May 22, 1919, pp. 971-976, 14 figs. Tool specially designed for quantity production.

MACHINERY, SPECIAL

Coke-Quenching, Screening and Loading Machine

Coke Quenching, Screening and Loading Machine. Gas World, vol. 70, no. 1811, Apr. 5, 1919, pp. 12-13, 1 fig. Machine consists of water-jacketed steel receptable, slightly larger than the coke oven, and mounted on steel-framed traveling structure running on rails. Endless chain conveyor propels charge of incandescent coke into receptacle without exposure to air.

Rolls

Design of Rolls for Making Ship and Boiler Plates. Machy. (Lond.), vol. 14, no. 342, Apr. 17, 1919, pp. 68-71, 4 figs. Drafts of slabbing and plate-mill rolls; universal mill; surface speed of rolls; rolling tin plate.

Separators, Centrifugal

Continuous Centrifugal Separation Machines. Engineering, vol. 107, no. 2776, Mar. 14, 1919, pp. 354-355, 7 figs. South African type which consists essentially of two bottomless buckets or vertical cylinders, revolving rapidly in a frame, around an upright spindle, each having an independent revolution on its own axis.

The Mauss Centrifugal Separators. E. M. Weston. Eng. & Min. Jl., vol. 107, no. 20, May 17, 1919, pp. 862-863, 6 figs. Type used for separation of colloids from slimes, particularly tin-ore slimes, consists of two bottomless buckets or vertical cylinders revolving rapidly in a frame around an upright spindle at a rate, for treatment of tin slimes, of 700 to 800 r.p.m.

See also MARINE ENGINEERING, Ships (Turbine Machinery).

MATERIALS OF CONSTRUCTION AND TESTING OF MATERIAL

Brass

The Effect of Work on Metal and Alloys. Owen Wm. Ellis. Metal Industry, vol. 14, no. 14, Apr. 4, 1919, pp. 284-288, 13 figs. Effect of reduction by rolling on alpha-beta brass determined by subjecting to deformation in the rolls a casting of 61:39 brass containing traces of impurities and having had no prior treatment.

Cement

Why Materials of Construction Should Be Tested Prior to Their Use. Emmanuel Mavant. Mun. & County Eng., vol. 53, no. 5, May 1919, pp. 184-186. Argues that cement should not be considered as standard material because there is always a possibility, even though remote, of its coming out too fresh, too high in sulphuric anhydride, in magnesia or too low in specific gravity.

China and Semi-Porcelain

Impact Tests and Porosity Determinations on some American Hotel China and Semi-Porcelain Plates. Homer F. Staley and J. S. Hromatko. Jl. Am. Ceramic Soc. vol. 2, no. 3, Mar. 1919, pp. 227-240, 6 figs. Vitrified hotel china plates tested were not found superior as a class to semi-porcelain plates in resistance to heavy impact blows; however, they are said not to have chipped with light blows, while semi-porcelain did. No direct relation was believed to be discernible between porosity and resistance to impact.

Cloth

Notes on the Quantitative Testing of Rain-proof and Waterproof Cloth. Geoffrey Martin and James Wood. Jl. Soc. Chem. Indus., vol. 38, no. 7, Apr. 15, 1919, pp. 84T-87T, 2 figs. Six ways of waterproofing are mentioned, and methods of determining which of these has been applied to given cloth are indicated.

Copper

The Influence of Cold-Rolling upon the Mechanical Properties of Oxygen-Free Copper. F. Johnson. Metal Indus. (Lond.), vol. 14, no. 14, Apr. 11, 1919, pp. 297-302, 14 figs. Method adapted to obtain sound piece of pure copper was to melt copper in graphite crucible under layer of fine charcoal, adding further portions step by step until crucible was full of molten copper. When solidified, metal was heated to 900 deg. cent. and forged on anvil. Results of tensile tests are tabulated and figures of maximum breaking load. Paper read before Inst. Metals.

Deformation of Cast Iron in Bending

Observations of Elastic and Permanent Deformations in Testing Cast-Iron and Steel Bars (Observations de déformations élastiques et permanentes dans les essais de flexion sur barreaux en fonte et en acier). J. Seigle. Bulletin l'Industrie Minérale, series 5, vol. 15, first issue of 1919, pp. 87-126, 30 figs. Characteristics of elastic curves of various specimens. Curves were drawn from values obtained in tests.

Fatigue of Metals

The Fatigue of Metals. H. F. Moore. Jl. Engrs. Club, Philadelphia, vol. 36-4, no. 173, Apr. 1919, pp. 138-142, 19 figs. Photomicrographs of specimens before and after stressing; proposed formula for failure-stress calculations; test data of repeated-stress tests.

Fuel Oil

Physical Tests of Fuel Oil. John W. Newton and F. N. Williams. Petroleum Age, vol. 6, no 5, May 1919, pp. 189-191. Discussion of various tests and apparatus required in laboratory with reference to U. S. Navy specifications for fuel oil. Third article.

Galvanized Sheets

Selection of Galvanized Sheets. Raw Material, vol. 1, no. 2, Apr. 1919, pp. 144-146, 5 figs. Concludes that from results of experiments and work done in commercial mill operations, the factors that are active in producing small granular spangles in galvanizing have their origin in the open-hearth process; and these causes can be eliminated only when sufficient care is taken to produce a steel substantially free from oxide.

Impact Testing Machine

The Eden-Foster Repeated Impact Testing Machine. Machy. (Lond.), vol. 14, no. 343, Apr. 24, 1919, pp. 105-109, 11 figs. Machine attempts to combine effect of vibration test and impact test by subjecting specimen to both shock and reversal of stress.

Mica

Raw Materials Needed in the Electric Industry. Mica (De quelques matières premières nécessaires à l'industrie électrique. Le Mica). Desiré Pector. Revue Générale de l'Electricité, vol. 5, no. 18, May 3, 1919, pp. 673-678. Location of mica deposits in the world; crystallization of various kinds of mica. (Continuation of serial.) Preceding articles appeared in R. G. E., vol. 4, July 20 & 27, 1918, pp. 87 and 121.

Porcelain (see also China)

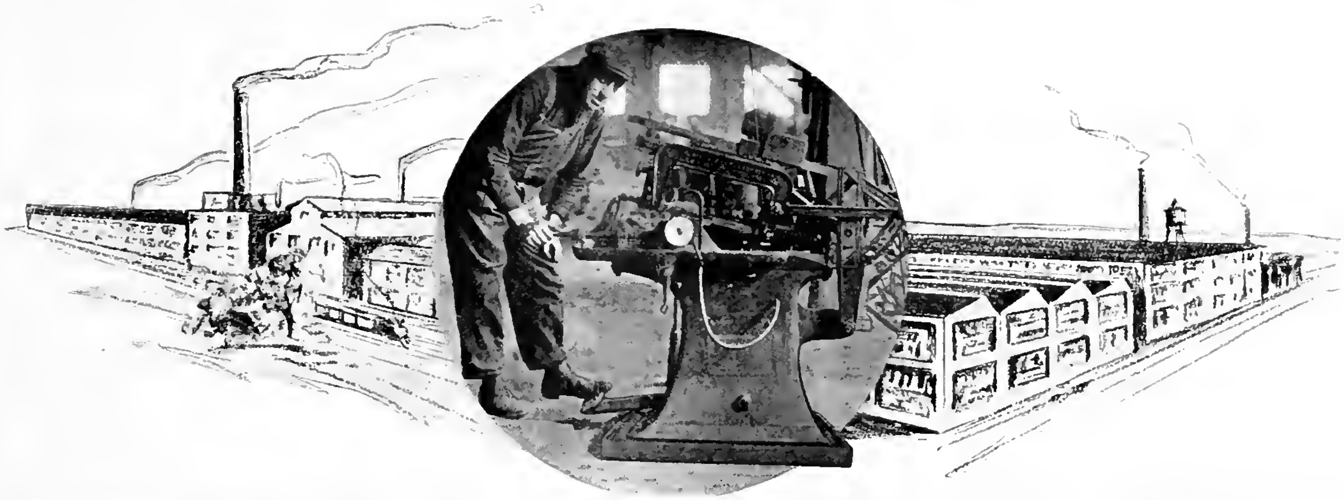
The Effect of Time and Temperature on the Microstructure of Porcelain. Albert B. Peck. Jl. Am. Ceramic Soc., vol. 2, no. 3, Mar. 1919, pp. 175-194, 15 figs. Petrographic microscopic examination reported as showing that quite dissimilar bodies can be produced by holding porcelain at a constant temperature for lengths of time which lie within variations of commercial practice, clay passing into amorphous silica and sillimanite which in turn passes into crystallized sillimanite.

Resistance of Materials

The Resistance of Materials—III. G. S. Chiles and R. G. Kelley. Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 241-243, 7 figs. Effect of sudden or abrupt changes in section on the distribution of the unit stress. Rubber specimens having cross rulings in white ink were subjected to stresses; diagrams of resulting distortions in rulings are shown.

Rubber (see also Resistance of Materials)

The Tensile Strength of Rubber-Sulphur Mixtures. O. de Vries and H. J. Hellendoorn. Jl. Soc. Chem. Indus., vol. 38, no. 7, Apr. 15, 1919, pp. 91T-93T, 4 figs. Stress and strain curves on Schopper testing machine.



Starrett Hack Saws

are more than just hack saws—each blade is a cutting tool especially designed to cut one or more kinds and shapes of metal most economically.

It's only a small shop with a wide range of miscellaneous work and very frequent changes that can afford to use one hack saw blade to cut every kind of metal.

The big concerns, cutting quantities of metal, work the Starrett way. They standardize by specializing because they've found it cheaper in cost per cut.

Follow the Starrett Hack Saw Chart LD and watch your cutting costs go down.

The L. S. Starrett Co.

THE WORLD'S GREATEST TOOLMAKERS
MANUFACTURERS OF HACK SAWS UNEXCELLED

Athol, Mass.

NEW YORK LONDON CHICAGO

STARRETT HACK SAWS CUT QUICKER LAST LONGER

42-934

X-Ray Examination of Materials

The Examination of Materials by X-Rays. Engineering, vol. 107, no. 2783, May 2, 1919, pp. 576-578, 1 fig. General discussion held at joint meeting of Faraday Soc. and Rontgen Soc.

MEASUREMENTS AND MEASURING APPARATUS

Dilatations, Measurements of

The Use of the Interferometer in the Measurement of Small Dilatations or Differential Dilatations, C. G. Peters. Jl. Wash. Acad. Sciences, vol. 9, no. 10, May 19, 1919, pp. 281-284. Equations for determining changes in length observable with dilatometer originated by Fizeau.

Flow Meters

Petrol Flowmeters and the Calibration of Jets, G. Smith-Clarke. Automobile Engr., vol. 9, no. 126, May 1919, pp. 140-146, 19 figs., also Automotive Industries, vol. 40, no. 21, May 22, 1919, pp. 1110-1113, 2 figs. Instruments devolved under specifications of standardization, requiring all jets to be calibrated under constant head of 100 cm. and stamping number upon jets indicating quantity of gasoline in cubic centimeters passed through in 1 min.

Fluid Pressure and Velocity

The Measurement of Fluid Velocity and Pressure, J. R. Pannell. Engineering, vol. 107, nos. 2776, 2777, 2778, Mar. 14, 21 & 28, 1919, pp. 333-334, 364-366, and 394-398, 23 figs. Hot-wire anemometers. Direction and velocity meter. Manometers and hydrometers. (Concluded.)

Kata-Thermometer

On the Cooling and Evaporative Powers of the Atmosphere, as Determined by the Kata-thermometer, Leonard Hill and D. Hargood-Ash. Proc. Roy. Soc., Series B., vol. 90, no. B. 632, Apr. 1, 1919, pp. 438-444, 3 figs. In observations taken the kata-thermometer was heated in hot water in a thermos flask, being kept in water till the air space at top was about half full of alcohol. For theory and use of kata-thermometer see Phil. Trans. (B, vol. 207, 1916, pp. 183-220.)

Moisture and Gases

Device for Measuring Small Quantities of Moisture in Gases, A. J. Crockatt and R. B. Forster. Jl. Soc. Chem. Indus., vol. 38, no. 8, Apr. 30, 1919, Trans. pp. 95T-96T, 1 fig. Fiber principle; chardonnet silk used.

Optical Methods of Measurement

Measuring to the Millionth Part of an Inch, Robert L. Clegg. Iron Age, vol. 103, no. 21, May 22, 1919, pp. 1345-1348, 8 figs. Optical method used by U. S. Bureau of Standards and other similar optical methods.

Snow Samplers

The Measurement of Snow, Robert E. Horton. Can. Engr., vol. 36, no. 18, May 1, 1919, pp. 426-427, 5 figs. Description of various samplers.

Scales

The Effect of Distance Between the Knife Edges on the Errors of Scales, C. A. Briggs. Scale Jl., vol. 5, no. 8, May 10, 1919, pp. 7-9, 4 figs. Assuming distance between load knife edge and fulcrum knife edge is changed by circumstances of rust or wear, or by error of construction, the resulting error in indication of scale is considered to depend on distance between knife edges and not on nominal multiplication of levers.

Spherometry

Refinements in Spherometry, G. W. Moffitt. Physical Rev., vol. 13, no. 4, Apr. 1919, pp. 261-271, 8 figs. Precision in mechanical methods is asserted to decrease rapidly as radius becomes larger; by auto-collimating method, up to limit of slide on turntable, precision is said to be high and independent of radius; methods are found to possess high degree of precision of measurement for concave surfaces of any radius and for measurement of convex surfaces to decrease in precision with increase of radius.

Tintometer

Estimation of Cyanogen Compounds in Concentrated Ammonia Liquor, Percy E. Spielmann and Henry Wood. Chem. News, vol. 118, no. 3077, Apr. 4, 1919, pp. 157-159. Calorimetric method employing the Lovibond tintometer.

Viscosity of Gasoline

Viscosity of Gasoline, Winslow H. Herschel. Technol. Papers of Bur. Standards, no. 125, May 5, 1919, 18 pp., 4 figs. Method of judging volatility and viscosity of gasoline by density is considered as only a rough approximation and measurement of fluidity by Ubbelohde viscosimeter is estimated as a preferable criterion.

MECHANICS

Cables, Suspended

Laying Aerial Lines (La pose des lignes aériennes), Emile Piérard. Société Belge des Electriciens, vol. 33, Jan.-Mar. 1919, pp. 10-40, 10 figs. Cloeren and Barbaret formulæ for determining tension in suspended cable. Writer proposes stretching to one-fourth ultimate strength at — 15 deg. cent.

Columns

Strength of Various Long Columns, William Jackson. Can. Engr., vol. 36, no. 21, May 22, 1919, pp. 467-468, 1 fig. Formulæ said to have been derived from results of a large number of tests on columns.

Plates

Maximum Tension in Square Plate Carrying Load Concentrated at Center (Valeurs maxima de la tension près de la face inférieure d'une plaque carrée supportant une charge unique concentrée en son centre), M. Mesnager. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 8, Feb. 24, 1919, pp. 392-395. Mechanical theory of plate supported at its periphery, taking into account thickness of plate.

Stresses in Beams and Trusses

Ladders, Robt. T. Reddy. Fire & Water Eng., vol. 65, no. 21, May 21, 1919, pp. 1133-1135, 10 figs. On the manner of using a truss ladder of form used by fire departments. Remarks based on theory of stresses in beams and trusses.

Stresses in Machines

Stresses in Machines When Starting and Stopping—V. F. Hymans. Automotive Eng., vol. 4, no. 4, Apr. 1919, pp. 189-190, 6 figs. Energy equations and mathematical calculations developed from consideration of forces on machine-tool parts without assuming that they are either at rest or in motion.

Trajectories

Formulæ of Trajectories (Sur les formules représentatives des trajectoires), M. Risser. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 8, Feb. 24, 1919, pp. 390-392. Parameters of compensating hyperbola.

MECHANICAL PROCESSES

Barrels, Steel

Manufacture of Steel Barrels. Machy. (Lond.), vol. 14, no. 342, Apr. 17, 1919, pp. 72-76, 12 figs. Blanking barrel heads, bending sheets for bodies; welding, flanging, brazing, bilging, pickling and testing.

Boilers

How to Design and Lay Out a Boiler—VII, Wm. C. Strott. Boiler Maker, vol. 19, no. 5, May 1919, pp. 137-139, 3 figs. Calculations for design of girth seams; layout of tubes; location of fusible plug and water-gage glass. (To be continued.)

Flues—II, George L. Price. Boiler Maker, vol. 19, no. 5, May 1919, pp. 128-130, 8 figs. Kinds of tools used on flue work and reasons for using them.

Chuck Manufacture

Universal Chuck Manufacture. Machy. (Lond.), vol. 14, no. 343, Apr. 24, 1919, pp. 101-104, 16 figs. Methods employed by F. Pratt & Co., Ltd., Halifax.

Crankshafts

Manufacture of Crank-Shafts for Aeroplane Engines, Richard Vosbrink. Metal Trades, vol. 10, no. 5, May 1919, pp. 219-221, 10 figs. Specifications require that pins and journals must be to size within plus or minus 0.0005 in.; other similar examples are quoted to indicate accuracy required.

Drawing Steel

Making Cold-Drawn Screw and Shaft Stock, Robert E. Clegg. Iron Age, vol. 103, no. 18, May 1, 1919, pp. 1129-1131, 5 figs. Factory of New England Drawn Steel Co. at Mansfield, Mass. Product is 3/16 in. to 1½ in. shafting and screw stock, rounds, hexagons and other shapes in cold-drawn free-cutting material.

Files

Some Points in the Manufacture of Files, Geo. Taylor. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 15, 34 pp., 29 figs., also abridged, Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 584-588, 12 figs. Pleads for definite and organized system of working in manufacture of files, such as will insure reliable quality of steel and production of blanks of uniform size and quality.

Gears

Gear Plant Makes War Record. Iron Trade Rev., vol. 64, no. 15, Apr. 10, 1919, pp. 947-952, 12 figs. How Falk Co. of Milwaukee organized for mass production of reduction gear sets for destroyers and cargo boats.

Hosiery Machinery

Manufacturing Banner Hosiery Machine—IV, Robert Mawson. Can. Machy., vol. 21, no. 20, May 15, 1919, pp. 481-483, 6 figs. Manufacturing operations on frames.

Liberty Motor Parts, Production of

Production of Liberty Motor Parts at Ford Plant, W. F. Verner. Mech. Eng., vol. 41, no. 6, June 1919, pp. 517-522 & 556, 11 figs. Describes process of forging cylinders from high-carbon steel tubing; also the 21 machining operations on bronze babbitt-lined crankshaft bearings. Paper for Spring Meeting of A.S.M.E.

Marine Engines

Building Marine Engines on a Quantity Basis, F. B. Jacobs. Mar. Rev., vol. 49, no. 6, June 1919, pp. 273-282, 13 figs. Hooven, Owens, Rentschler Co. of Hamilton, O., said to be completing four 2800-hp. 3-cyl., triple-expansion, inverted-type marine engines per week. First article of a series, dealing with heavy units such as cylinders, crankshafts, bed plates, connecting rods, etc.

Milling-Machine Manufacture

Special Operations in Milling Machine Manufacture, F. B. Jacobs. Iron Trade Review, vol. 64, no. 14, Apr. 3, 1919, pp. 893-896, 13 figs. Seasoning of castings accomplished by exposing them to weather for a number of weeks, during which time they expand and contract with change in temperature from midday to midnight.

Rolling Mills

19,000-Hp. Electric Reversing Rolling Mill Equipment. Engineer, vol. 127, no. 3301, Apr. 4, 1919, pp. 334-336, 6 figs. Motor comprises three units rigidly coupled together and mounted on common bedplate.

New Steel Works Built in England, Joseph Horton. Iron Trade Review vol. 64, no. 14, Apr. 3, 1919, pp. 879-883, 5 figs. Arrangement of 36-in. blooming mill and 21- and 18-in. bar mills at Phoenix Special Steel Works, Sheffield.

Pointers on the Designing of Wire Rod Mills, W. S. Standiford. Can. Machy., vol. 21, no. 18, May 1, 1919, pp. 426-429, 4 figs. Design of roll passes developed for manufacture of wire used in entanglements in front of trenches.

Vise Manufacture

How the Reed Vise is Made, J. V. Hunter. Am. Mach., vol. 50, no. 20, May 15, 1919, pp. 923-926, 14 figs. Machining operations used by Reed Mfg. Co., Erie, Pa., especially in regard to obtaining interchangeability of parts.

MOTOR-CAR ENGINEERING

Daimler

The Daimler 2-3 Tonner. Motor Traction, vol. 28, no. 739, Apr. 30, 1919, pp. 373-375, 7 figs. Specifications: 22.4-hp., 4-cyl., sleeve-valve engine; gross loaded weight allowable, 5½ tons; four forward and one reverse speeds; overhead worm.

Gazelle

The 8-hp. Gazelle. Autocar, vol. 42, no. 1227, Apr. 26, 1919, pp. 616-618, 6 figs. Four-cyl. French car. Some of specifications are: forced lubrication, 3-speed gear box, and bevel-driven back axle.

Military Trucks

Military Transport Chassis—XI & XIV. Automobile Engr., vol. 9, nos. 123 & 126, Feb. 1919, and May 1919, pp. 39-42 & 137-139, 9 figs. Performance of Kelly Springfield K 40 (3½ ton) and Packard "4D" truck under war conditions.

Tractor Engines

Fuel Limitations of Tractor Engines, H. L. Horning. Automotive Industries, vol. 40, no. 19, May 8, 1919, pp. 1001-1003 and 1043. Hints on overcoming common troubles. Paper read before Soc. Automotive Engrs.

See also MUNITIONS AND MILITARY ENGINEERING *(Automobile Service, French)*; ORGANIZATION MANAGEMENT, *Factory Management (Repair Shop, Automobile.)*

POWER GENERATION

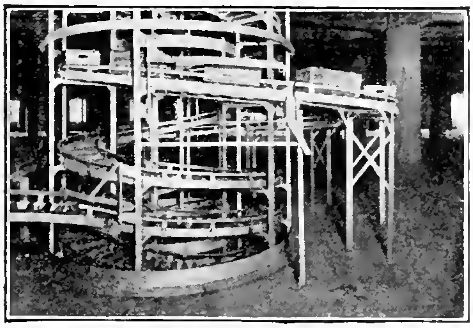
Delivery and Relative Fall Determination

Utilization of Hydraulic Energy (Programme d'étude pour l'aménagement des forces hydrauliques), R. de la Brosse. Houille Blanche, vol. 18, no. 25-26, Jan.-Feb. 1919, pp. 1-5. How to determine delivery and relative fall; their sig-

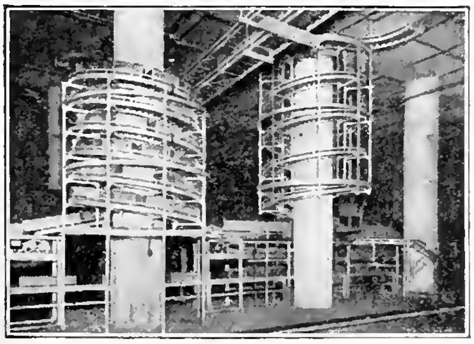
Lamson Conveyors

Flowing out of cars past inspectors

To upper floors via overhead space



Switched into storage on any floor



Flowing storage above car platform and direct distribution to cars

Human Hands Never Lift BEVO Cases

THE Lamson Conveying System installed in the Anheuser-Busch Bevo plant is a typical example of the way Lamson eliminates manhandling — trucking or carrying — throughout a factory.

In the Bevo plant, Lamson Conveyors set the pace for a continuous flow of production without aid by human hands. From the time Bevo cases are first placed on Lamson Conveyors until they flow to storage or freight cars, they are never lifted by human hands. While Bevo bottles are being washed, filled, capped, labeled, and inspected, Bevo cases are conveyed at a pace regulated to the capacity of each machine and each operator. No time is lost in waiting for cases to come along, in stooping, or in reaching. Lamson Conveyors see to it that Bevo cases always arrive on schedule time.

Lamson Conveying Systems are as varied as industry itself, yet each one is largely or wholly made up from a few standard units. Lamson Conveyors increase production and cut down costs; they save floor space, stop congestion and confusion; they bring about a new conception of "full capacity." With post-war labor and cost conditions they are economic necessities.

The Lamson Booklet on Conveying will be sent on request, or our nearest representative will be glad to call. It involves no obligation.

THE LAMSON COMPANY

100 BOYLSTON ST., BOSTON, MASS.

Boston	100 Boylston Street	Denver	1622 Arapahoe Street

LAMSON SERVICE

nificance in calculation of available energy. Reference is made by way of illustration to region of Pyrenées and central basin of France.

New England

War-Time Service Problems in New England. Elec. World, vol. 73, no. 20, May 17, 1919, pp. 1007-1019, 31 figs. Details of plant growth, connected load and enforced economies are presented as factors which have contributed to establish reliability of central station service.

New South Wales

White Bay Power Station of the New South Wales Railways, O. W. Brain. Tramway & Ry. World, vol. 45, no. 18, Apr. 10, 1919, pp. 177-186, 6 figs. Plant supplies traction current for Sydney's tramways and also furnishes electric power for railway and tramway workshops, and various auxiliary services of department throughout metropolis, including signaling system, elevators, conveyors, lifts, pumps, air compressors, etc. Paper read before Elec. Assn. of Australia.

New Zealand

Hydro-Electric Development of New Zealand, E. Parry. Elec. Times, vol. 55, no. 1436, Apr. 24, 1919, pp. 259-260, 1 fig. Report of chief electrical engineer to Minister of Public Works.

Niagara Falls

Niagara Falls a War-Load Center. Elec. World, vol. 73, no. 20, May 17, 1919, pp. 996-1000, 4 figs. How electrochemical and electrometallurgical loads were helped by interconnection of power.

Norway

Utilization of Water-Power in Norway (Statens forhold til vandkraften). Teknisk Ukeblad, vol 66, no. 11, Mar. 14, 1919, pp. 156-160. For domestic heating, lighting and power purposes in place of imported coal. Comparison of costs.

Pacific Coast

Pacific Coast Plants Fully Loaded. Elec. World, vol. 73, no. 20, May 17, 1919, pp. 1031-1037, 12 figs. Interconnection of system is claimed to have enabled Western companies to carry increased loads despite lack of hydroelectric development.

Southern States

How the South Handled War-Time Loads. Elec. World, vol. 73, no. 20, May 17, 1919, pp. 1022-1030, 12 figs. Extensions and interconnections of transmission lines, particularly installation of reserve steam plant by Alabama Power Co.

Tennessee

The Larger Undeveloped Water-Powers of Tennessee, J. A. Switzer. State of Tenn. Geol. Survey, bul. 20, 1918, 35 pp., 30 figs. Description of existing plants and scheme for the utilization of available energy. Paper presented before Am. Electrochemical Soc.

United States

The Question of Hydro-Electric Development, D. H. Colcord. Elec. Eng., vol. 53, no. 2, Feb. 1919, pp. 59-63, 4 figs. Estimate of undeveloped resources in the U. S. A. is considered as 60,000,000 hp. Economic and other causes affecting development in various sections are mentioned.

POWER PLANTS

Boiler Efficiency

Graphic Calculation of Boiler Efficiency, Ralph E. Turner. Power Plant Eng., vol. 23, no. 10, May 15, 1919, pp. 450-451, 4 figs. Chart for calculating combined boiler and furnace efficiency when feed water is measured in cubic feet or pounds.

Boiler Room, Air Supply for

The Air Supply to Boiler Rooms, Richard W. Allen. Tran Inst. Marine Engrs., vol. 30, no. 241, Mar. 1919, pp. 347-387, 38 figs. Report of investigation conducted in various vessels where closed stokehole systems had been adopted.

Boiler Supports

Reinforced Concrete Supports for Horizontal Tubular Boilers, H. E. Dart. Locomotive, Hartford Steam Boiler Inspection & Insurance Co., vol. 32, no. 5, Jan. 1919, pp. 130-142, 4 figs. Reinforced concrete is preferred for supporting suspended boilers because it is said that all of the material used (including reinforcing rods, lumber for forms, cement, sand, stone and water) are much more easily obtainable than structural-steel shapes and cast-iron columns and there is no delay in waiting for any of them to be fabricated.

Condensers

Notes on Surface Condensing Plants, with Special Reference to the Requirements of Large Power Stations, R. J. Kaula. Eng. & Indus Management, vol. 1, no. 2, Apr. 24, 1919, pp. 342-346, 4 figs., also Elecn., vol. 82, no. 17, Apr. 25, 1919, pp. 488-490, 3 figs., and Engineering, vol 107, no. 2781, Apr. 18, 1919, pp. 522-524, 5 figs. Deals with problem of tube erosion. Advantage to be derived on siphonic circulating water system by adopting parallel-flow principle. Paper presented before Instn. Elec. Engrs.

Hotel Plants

Plant of the Hotel Traymore. Power, vol. 49, no. 20, May 20, 1919, pp. 760-762, 5 figs. Plant comprises six 200-hp. water-tube boilers in three batteries. Building is heated with exhaust steam.

Electric and Elevator Equipment of the Hotel Pennsylvania, Chas. E. Knox. Power, vol. 49, no. 19, May 13, 1919, pp. 708-712, 8 figs. After studying possible methods of supply it was agreed upon to purchase steam and electricity from Pennsylvania R. R. and to install only a single engine-driven 500-kw. electric generator to be run during winter months, exhaust being used for heating and hot-water supply.

Oil-Fuel Plants

Economy of Arizona Power Plants Using Oil Fuel, C. R. Weymouth. Mech. Eng., vol. 41, no. 6, June 1919, pp. 523-526, 3 figs. Tables and curves of operating characteristics of three plants, embodying various similar features, but differing in methods of condensing, are presented. Paper for Spring Meeting of A. S. M. E.

Plants

Power Installation at the Old Hickory Powder Plant near Nashville, Tennessee. Power, vol. 49, no. 20, May 20, 1919, pp. 748-755, 8 figs. Equipment includes sixty-eight 823-hp. boilers, fifty-two 350-hp. engines, 17,500-kw. in turbo-generators and 13 ammonia compressors driven by uniflow engine.

Power Plant Installation of the Braden Copper Co. at Rio Pangal, Chile (Instalación de fuerza motriz para la Braden Copper Co. en Rio Pangal, Chile), H. L. Cooper. Ingeniería Internacional, vol. 1, no. 2, May 1919, pp. 77-80, 5 figs. Details of hydroelectric plant with special reference to conduits.

Prime-Mover Plants

Tendencies in Prime-Mover Practice. Elec. World, vol. 73, no. 21, May 24, 1919, pp. 1106-1109, 4 figs. Advises that continuous service be safeguarded as steam turbines of great size are adapted.

Pulverized-Coal Plant

Equipment for Using Pulverized Coal. Can. Mfr., vol. 39, no. 5, May 1919, pp. 40-42. Features of distributing system and waste-heat boilers at plant of Armstrong, Whitworth Co. of Canada, Ltd., at Longueuil, P. Q.

Steel-Mill Plants

Steel-Mill Electric Drive—Present Status and Recent Developments, Brent Wiley. Elec. Rev., vol. 74, no. 19, May 10, 1919, pp. 737-740, 6 figs. One of noteworthy features of recent practice described is selection of large-size turbine units and a more liberal policy to provide for general plant electrification; this is approved on the ground that water rate of large-size turbines is materially better than for size of units formerly selected for mill use.

Superheaters

Superheaters at Collieries, Edward Ingham. Colliery Guardian, vol. 117, no. 3045, May 9, 1919, pp. 1084-1085. In order to avoid unnecessary blowing off, writer believes superheater safety valve, which he recommends as a safety measure, should be loaded to pressure a few pounds in excess of that to which boiler safety valve is loaded.

Turbo Generators

A Big Turbine-Generator Equipment, J. P. Rigsby. Elec. Eng., vol. 53, no. 4, Apr. 1919, pp. 156-159, 1 fig. Westinghouse cross-compound double unit, 45,000 kw. type, installed in power station of Narragansett Electric Light Co., Providence, R. I.

Sixty Thousand-Kw. Turbine Installation, W. S. Finlay. Elec. Jl., vol. 16, no. 5, May 1919, pp. 172-182, 24 figs. Features specially proposed in design of scheme were concentration of auxiliary equipment and piping to provide ready access to machinery, valves, etc., placing auxiliaries within reach of cranes to facilitate dismantling and overhauling during off-peak hours, and avoiding right-and left hand arrangements in auxiliary units in order to reduce necessary stock of spare parts.

See also MINING ENGINEERING, Mines and Mining (Power Plants); MARINE ENGINEERING, Ships (Boilers).

POWER TRANSMISSION

Belting

Relative Efficiency of Different Kinds of Belting, E. W. Bowman. Wood-Worker, vol. 38, no. 3, May 1919, p. 40, 1 fig. Chart of horsepower slip curves obtained from comparative tests.

Motor Location

Effective Transmission Most Essential to Economy, J. H. Rodgers. Power House, vol. 12, no. 6, May 5, 1919, pp. 147-154, 18 figs. Location of motor drive about midway of shaft length claimed to minimize shaft torque.

PRODUCER GAS

Gas Producers

Practical Operation of Gas Producers, J. S. M'Climon. Blast Furnace & Steel Plant, vol. 7, no. 5, May 1919, pp. 230-233, 4 figs. Methods of measuring fire. Generating of hot and cold gas; steam requirements. Purpose of article is to offer method for systematizing operating conditions in ordinary plant.

PUMPS

Corrosive Liquors, Pumping

Pumping Corrosive Liquors. Engineering Review, vol. 32, no. 10, Apr. 15, 1919, pp. 296-297, 2 figs. Pumps made of "ceratherm." This material is an earthenware composition said to be insensible to sudden changes of temperature.

Hydraulic Pumps

Steel Works Machinery. Engineering, vol. 107, no. 2783, May 2, 1919, pp. 567-569, 5 figs. Typical battery of hydraulic pumps. Features taken up are driving motor, working pressure, single-reduction gear with double helical machine-cut teeth, valve chambers and pump barrels of forged steel with renewable bronze valves and seats arranged for quick removal. (To be continued.)

REFRIGERATION

Ethyl and Methyl Chloride

Properties of Ethyl and Methyl Chlorides, Charles H. Herter. Refrig. World, vol. 54, no. 5, May 1919, pp. 11-14 and 27-28. Attention is called to possibilities of methyl chloride as refrigerating agent.

Ice Plants

Deterioration of Ice Plants, Fred Ophuls. Refrig. World, vol. 54, no. 5, May 1919, pp. 21-22. Advises giving attention to repairs immediately defects are known as means to prevent rapid deterioration.

The Toronto Plant of the Wm. Davies Co., W. F. Sutherland. Power House, vol. 12, no. 5, Apr. 25, 1919, pp. 111-113, 7 figs. Ice plant.

Insulation, Cold-Storage

Cold Storage Insulation: Government Research. Cold Storage & Produce Rev., vol. 22, no. 253, Apr. 17, 1919, pp. 85-86, 1 fig. Report of tests at Nat. Physical Laboratory conducted by immersing large coil of piping in insulating material under test, and obtaining heat transmitted from the observed rise of temperature of the brine stream.

See also RAILROAD ENGINEERING, Rolling Stock (Refrigerator Cars); ELECTRICAL ENGINEERING, Generating Stations (Ice Making and Refrigeration); MECHANICAL ENGINEERING, Hydraulic Machinery (Ice Troubles).

RESEARCH

Bureau of Mines, Pittsburgh Station

The New Pittsburgh Station of the Bureau of Mines—III & IV, George W. Harris. Coal Age, vol. 15, nos. 19 & 20, May 8 and 15, 1919, pp. 852-855, and 907-911, 11 figs. Analytical apparatus used in analysis of coal. Researches on combustion of coal in furnaces and absorption of heat by boiler.

Industrial Research Laboratories

Industrial Physical and Mechanical Research Laboratories (Les laboratoires d'enseignement et de recherches de physique et mecanique industrielles), Jean Villey. Revue Générale des Sciences, vol. 30, no. 8, Apr. 30, 1919, pp. 233-240. Scheme of coöperation between universities and industries. Its adoption expected to be important factor in developing French industry.

The Relationship between the Laboratory and the Workshop, W. R. Barclay. Metal Indus. (Lond.), vol. 14, no. 14, Ap. 11, 1919, pp. 306-309. Likeness of principles of operation and objects of accomplishment in laboratory and in workshops.

Co-ordination of Research in Works and Laboratories, H. R. Constantine. Elecn., vol. 82, no. 16, Apr. 18, 1919, pp. 464-466. Scheme for establishing a self-supporting Board of Research. Board is to be treated in a similar way

to Boards of Trade and Education. Paper before Instn. Elec. Engrs.

Municipal Testing Laboratories

The Organization of a Standard Municipal Testing Laboratory, J. O. Preston. Can. Engr., vol. 36, no. 21, May 22, 1919, pp. 480-482. Installation of municipal laboratory for purpose of developing uniform standards and establishing fair basis for purchase of materials as well as securing proper usage of them.

Photography

Photography in Research, Arthur G. Eldredge. Chem. & Metallurgical Eng., vol. 20, no. 10, May 15, 1919, pp. 506-510, 14 figs. Examples of applications in industry and their considerations on opporunities of development.

Testing Equipment—Armour Inst. of Technology

Armour's Special Testing Equipment. Power, vol. 49, no. 18, May 6, 1919, pp. 670-673, 9 figs. Among other equipment which the Armour Inst. of Technology employs are apparatus for determining horsepower of automobile engines, influence of impact, bearing friction, belt slippage and heat flow through any material that can be prepared in flat slabs.

See also MARINE ENGINEERING, Ships (Model Experiments); RAILROAD ENGINEERING, Locomotives (Tests); AERONAUTICS, Testing.

SPECIFICATIONS

Steel

Specifications for Steel. Times Eng. Supp., vol. 15, no. 534, Apr. 1919, p. 130. Chemical specifications are not believed to be an expression of physical properties; it is said that much steel has been found serviceable which has been condemned on its chemical specification.

STANDARDS AND STANDARDIZATION

Sulphur Boiling Point

The Standardization of the Sulfur Boiling Point, E. F. Mueller and H. A. Burgess. Jl. Am. Chem. Soc., vol. 41, no. 5, May 1919, pp. 745-763, 4 figs. Importance of sufur boiling point as defining a standard temperature, and the necessity of obtaining further evidence upon certain questions concerning effect of experimental conditions upon the results obtained in its use, are considered.

See also RAILROAD ENGINEERING, Locomotives (Standard Locomotive.)

STEAM ENGINEERING

Boiler Power vs. Tractive Power

Boiler Power Versus Tractive Power—II, Wm. N. Allman. Boiler Maker, vol. 19, no. 5, May 1919, pp. 132-134, 2 figs. Graph showing percentage of boiler pressure for various piston speeds for both saturated and superheated steam, designed for use in calculating tractive power at any desired speed and to determine hp. (To be continued.)

Turbines, Large

The Large Steam Turbine, J. F. Johnson. Jl. Engrs. Club Philadelphia, vol. 36-5, no. 174, May 1919, pp. 174-183, 7 figs. Graph indicating relative steam consumption for units of various capacities designed for equal costs per kw. hour; records of performance of large turbine units; notes on design and construction. Paper read before Phila. Section Am. Soc. Mech. Engrs.

Three-Cylinder, 60,000-Kw. Turbine Installation, W. S. Finlay, Jr. Elec. World, vol. 73, no. 19, May 10, 1919, pp. 933-935, 4 figs. Operating details of three-element turbo-generator fitted with automatic control which enables any two elements to do the work of three in case of trouble.

Interborough Commission's 60,000 Kw, Turbo-Generator Unit, W. S. Finlay, Jr. Elec. Ry. Jl., vol. 53, no. 19, May 10, 1919, pp. 906-907, 3 figs. Attention is directed particularly to automatic control features of installation.

See also RAILROAD ENGINEERING, Locomotives (Comparative Efficiencies, Compound and Simple Locomotives.)

TEXTILES

Slashing of Cotton Warps

Slashing of Cotton Warps, Everett H. Hinckley. Textile World Jl., vol. 55, no. 19, May 10, 1919, pp. 61-63, 9 figs. Tests to determine influence of temperature on finer work.

Soaps, Scouring and Fulling

Properties of Scouring and Fulling Soaps, F. Albert Hayes. Textile World Jl., vol. 55, no. 21, May 24, 1919, pp. 21 and 33, 4 figs. Theories as to deterrent power and photomicrographs showing structure of wool fiber.

WELDING

Crankshaft Welding

Welding Broken Crankshafts, J. H. Deppeler. Iron Age, vol. 103, no. 19, May 8, 1919, p. 1217, 2 figs. Suggestions in regard to methods of lining up broken parts for thermit process.

Electric Welding

Electric Welding, W. H. Gard. Times Eng. Supp., vol. 15, no. 534, Apr. 1919, p. 137. Experiences in warships.

Electric Welding; Its Theory, Practice, Application and Economics, H. S. Marquand. Elecn., vol. 82 nos. 16, 17, 18 & 19, Apr. 18 & 25, May 2 & 9, 1919, pp, 468-469; 495-496; 515-517, and 541-543; 16 figs. Deals generally with Thomson process of resistance welding; describes plant used for spot welding, seam welding and butt welding; application of method to chain welding, tire and wire welding; spot-welding curves for equal thickness of sand-blasted plates and butt-welding curves for copper. (Continuation of serial.)

Electric Welding and Welding Appliances—VIII, IX, X, XI, XII. Engineer, vol. 127, nos. 3301, 3302, 3303, 3304, 3305, Apr. 4, 11, 18, 25, and May 2, 1919, pp. 319-322, 352-354, 375-378, 394-396 & 421-422, 36 figs. Resistance welders of Electric Welding Co. Holmes portable generating sets; plant consists of 4-cyl. gas engine of 28 b. hp. coupled to d. c. compound-wound dynamo having output of 250 amperes at 65 volts. Process followed by Steel Barrel Co., Ltd., in manufacture of steel drums.

The Technique of Arc Welding, F. A. Anderson. Jl. Electricity, vol. 42, no. 9, May 1, 1919, pp. 437-439, 23 figs. Methods of preparing work and detecting faults.

A Review of Some Modern Methods of Arc Welding, Thomas H. Heaton. Can. Machy., vol. 21, no. 19, May 8, 1919, pp. 463-465, 3 figs. Comparison of Benardos, Kjelberg and quasi-arc systems. (To be continued.)

Electric Welding, James Caldwell and Henry Bailey Sayers. Engineering, vol. 107, no. 2776, Mar. 14, 1919, pp. 350-351. Developments in Great Britain and U. S. A.; experiments on application of electric welding to large structures; application of electric welding in ship construction and repairs. Abstracts of papers read before Instn. Civ. Engrs.

Equipment Designed for Electric Arc Welding—III, E. Wanamaker and H. R. Pennington. Ry. Elec. Engr., vol. 10, no. 5, May 1919, pp. 141-146, 14 figs. Types used in different systems, operating characteristics and circuits.

Electric Arc Welding for Repairing of Steel Parts (Soldadura de piezas de acero por medio del arco electrico), O. H. Eschholz. Boletin de la Asociacion Argentina de Electro-Tecnicos, vol. 4, no. 12, Dec. 1918, pp. 902-905, 2 figs. Small arc and proper control of flame claimed to insure minimum oxidation of arc vapors and superficial deposits. (Concluded.)

Experiments on the Application of Electric Welding to Large Structures, Wescott Stile Abell. Steamship, vol. 30, no. 359, May 1919, p. 257. Account of experiments carried out on behalf of Lloyd's Register of Shipping, in order to determine possibility of application of electric arc welding to ship construction. Paper read before Instn. Civil Engrs.

Electric Welding and Its Applications, Walter Leonard Lorkin. Tramway & Ry. World, vol. 45, no. 18, Apr. 10, 1919, pp. 197-200, 9 figs. Endeavors to show that process is simple, that it can be carried out with ordinary labor and that the welds are efficient and effected at small cost. Paper read before Roy. Soc. Arts.

Gas Torches

Modern Welding and Cutting—XII, Ethan Viall. Am. Mach., vol. 50, no. 21, May 22, 1919, pp. 977-983, 21 figs. Description of various makes of gas torches.

Inspection of Welds

Inspection of Metallic Electrode Arc Welds. Elec. Traction, vol. 15, no. 5, May 1919, pp. 330-334, 7 figs. Graphs indicating approximate arc current and electrode diameter for welding steel plates of various thicknesses, also variation in weld strength with change in arc current.

Oxy-Acetylene Welding

Oxy-Acetylene Apparatus and Its Accomplishments in the M. C. T. Reconstruction Camp in France, George N. Sieger. Welding Engr., vol. 4, no. 5, May 1919, pp. 19-23, 7 figs. Work of salvage, repair and reconstruction. Personnel of welding shop. Installation of compression plant.

Safety Rules for Oxy-Acetylene Welding. Boiler Maker, vol. 19, no. 5, May 1919, pp. 134 and 136. Adopted by Western Pa. Div. of Nat. Safety Council.

Modern Welding and Cutting—X, Ethan Viall. Am. Mach., vol. 50, no. 18, May 1, 1919, pp. 833-838, 7 figs. Details regarding acetylene in cylinders and description of positive-pressure type of generator.

Sheet and Tube Welding (see Thin Plates)

Autogenous Welding at Albuquerque, H. Louis Hahn. Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 271-272, 7 figs. Repairing burned or cracked sheets and tubes by gas or electric welding; welding of flue beads.

Steel Castings

The Welding of Steel Castings, J. F. Springer. Ry. & Locomotive Eng., vol. 32, no. 5, May 1919, pp. 142-143, 1 fig. Effect of carbon percentage in behavior of casting when being welded.

Testing Welds

A Review of Some Modern Methods of Arc Welding, Thomas H. Heaton. Can. Machy., vol. 21, no. 20, May 15, 1919, pp. 490-492, 9 figs. Application of petroleum is considered a good test of a weld because of its penetrating quality.

Thin Plates

The Gas Welding of Thin Plates—II, J. F. Springer. Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 268-271, 2 figs. Requirements of thin work with and without use of rods; behavior of various metals.

See also MARINE ENGINEERING, Yards (Welding); RAILROAD ENGINEERING, Construction (Welding Outfits), Shops (Welding.)

WOOD

Creosote Treatment

Creosote Treatment of Car Timbers. Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 255-257, 3 figs. Methods used by Marsh Refrigerator Service Co. Cost of work and estimates of increased life.

Forest Conservation

A Program of Forest Conservation for the South, J. G. Peters. Jl. Forestry, Soc. Am. Foresters, vol. 17, no. 4, Apr. 1919, pp. 364-370. Argues that since states and Federal Government disposed of Southern lands to such an extent as to make it impossible for the small population of these states to develop adequately and use the land, the states and the Federal Government have contracted obligation in the matter at least until owners can be expected to handle land properly. Paper read before Soc. Am. Foresters, Washington Section.

Tasmanian Hardwood

Use of Tasmanian Hardwood in Holland (Eene toepassing van Tasmanisch hardhut), S. Van Ravensteijn. De Ingenieur, vol. 34, no. 11, Mar. 15, 1919, pp. 197-200, 4 figs. Blue-gum wood has been used for 380 yd. of quays at Dordrecht, and while it has not yet proved its durability, it is not expected that it will equal that of oak.

Timber Estimating

A Formula Method for Estimating Timber, E. I. Terry. Jl. Forestry, Soc. Am. Foresters, vol. 17, no. 4, Apr. 1919, pp. 413-422, 1 fig. Worked out by using merchantable form factor and ratio between average cubic and board-foot contents of trees of each diameter class.

VARIA

Education of Engineers

Education and Training of the Engineer, A. P. M. Fleming. Tran. Inst. Mar. Engrs., vol. 31, no. 242, Apr. 1919, pp. 2-11 and (discussion) pp. 12-21. Considers as a matter of primary concern that a rigid selection be made among the larger supply of youths applying for entry into the engineering profession of only those boys who appear to have mental, moral, and physical capacity for availing themselves to the utmost of the course of training provided.

Engineering School Laboratories

Mechanical, Physical and Chemical Laboratory of the Engineering School of Lausanne University (Le laboratoire d'essais mécaniques, physiques et chimiques de l'école de l'Université à Lausanne). Bulletin Technique de la Suisse Romande, vol. 45, no. 8, Apr. 19, 1919, pp. 70-74, 8 figs. Description of 50-ton oil press.

Glass Vessel Marking

The Permanent Marking of Glass Vessels, Joseph C. Bock. Chem. News, vol. 118, no. 3077, Apr. 4, 1919, pp. 161-162. Proposes the use of glass color fused in the glass by means of ordinary burner. From Jl. Am. Chem. Soc.

Perpetual-Motion Machines

Perpetual Motion Machines, B. F. Jakob-

sen. Jl. Electricity, vol. 42, no. 9, May 1, 1919, pp. 426-427, 6 figs. Absurdity implied in their conception.

Telescope, 72-in. Canadian

The Dominion of Canada's 72-In. Telescope, J. S. Plaskett. Nature, vol. 103, no. 2580, Apr. 10, 1919, pp. 105-108, 3 figs. Reflecting type; article deals with optical parts, on work being done and proposed to be done with the instrument.

Organization and Management

ACCOUNTING

Army, U. S.

The Cost Accounting System of Construction Division, U. S. Army, C. W. Pinkerton. Eng. & Contracting, vol. 51, no. 21, May 21, 1919, pp. 548-551, 5 figs. Basis is foreman's daily report blank.

Factory Costs

New System Computes Factory Costs, W. A. Rutz. Iron Trade Rev., vol. 64, no. 16, Apr. 17, 1919, pp. 1023-1024. Method used by Am. Multigraph Co., Cleveland. System is based on principle that stock room is a bank.

Production Charges, Indirect

Fixing Indirect Production Charges, M. H. Potter. Iron Trade Rev., vol. 64, no. 18, May 1, 1919, pp. 1148-1149, 1 fig. Chart showing connection between various items offered as preliminary step in classifying indirect charges.

EDUCATION

Apprentices

Theoretical Training for Apprentices—Outline of the Educational Facilities Provided at the British Government Arsenal, E. G. Timbrell. Can. Engr., vol. 36, no. 18, May 1, 1919, pp. 423-425. Apprentices must be between 14-16 years of age. Course of four years covering mathematics, experimental mechanics, chemistry and engineering drawing, given three evenings per week, with addition of one-half day.

Home of the Canadian Ingersoll-Rand Co. Can. Machy., vol. 21, no. 19, May 8, 1919, pp. 451-455, 8 figs. Particular reference is made to apprenticeship systems and practices followed in forging department.

Women, Wireless Workers

Telephone and Wireless Transmission. Elec. Eng., vol. 53, no. 1, Jan. 1919, pp. 15-17. Training given women workers in Westinghouse plant.

FACTORY MANAGEMENT

Boiler Manufacturing

Modern Management in Boiler Manufacturing, Chas. M. Horton. Boiler Maker, vol. 19, no. 5, May 1919, pp. 122-123. Advises systematic continuity in turning out product.

Fordson Assembly Methods

Fordson Assembly Wholly on Progressive Plan—II, J. Edward Schipper. Automotive Industries, vol. 11, no. 18, May 1, 1919, pp. 960-966, 11 figs. Cylinder block and transmission housing assemblies travel along parallel lines until complete.

Haulage, Inter-Shop

Saving $200 a Day in Inter-Shop Haulage, R. M. Kinny. Factory, vol. 22, no. 5, May 1919, pp. 926-929, 9 figs. Minneapolis Steel & Machinery Co. have added a railroad despatching system to the use of ordinary industrial trucks with trailers.

Human Element

The Human Element in the Factory, Hugh K. Moore. Eng. & Indus. Management, vol. 1, no. 2, Apr. 24, 1919, pp. 327-331, 3 figs. Boiler performance curves for various forms are examined and conclusions are derived concerning influence of personal touch between employer and employee in creating research initiative in the latter.

Layout

Continental Plant Layout Facilities Production. Automotive Industries, vol. 40, no. 21, May 22, 1919, pp. 1122-1126, 10 figs., on supp. plate. Engine shipments go out on same tracks on which raw parts enter. (To be continued.)

The Designing of Factory Layouts for the Clay Industries, T. W. Garve. Jl. Am. Ceramic Soc., vol. 2, no. 3, Mar. 1919, pp. 195-207, 4 figs. Interior and selection of machinery as affected by kind and quantity of ware to be made, physical conditions of clay and local conditions and requirements.

Pattern Control

A Simple Pattern Control and Routing System. Foundry, vol. 47, no. 7, May 15, 1919, pp. 292-296, 11 figs. Method worked out at Canton Steel Foundry Co. It is based on five standard forms operated from central office.

Payroll Systems

Installing Accurate Payroll System, Clifford E. Lynn. Iron Trade Rev., vol. 64, no. 20, May 15, 1919, pp. 1289-1292, 9 figs. Maintenance of timekeeping and distribution method by co-operation of superintendent, foremen and workmen.

Production Control

Controlling Production in a Motor Plant, Charles Lundberg. Iron Age, vol. 103, no. 20, May 15, 1919, pp. 1279-1281, 10 figs. Obtainable from methods used by Mechanical Appliance Co., Milwaukee, are determination of comparative production, of labor costs, stage of manufacture each lot has reached at any time, quantity of each piece on hand or in process and deduction of faulty work.

Purchasing

Handling Orders in Steel Plants, Clifford E. Lynn. Iron Trade Rev., vol. 64, no. 15, Apr. 10, 1919, pp. 956-958, 3 figs. General forms by which purchase requirements are received, recorded and executed.

Repair Shop, Automobile

The Scientific Management of the Automobile Repair Shop (Application des principes de l'organisation scientifique à l'atelier central de réparations du service automobile). J. Compagnon. Bulletin de la Société d'Encouragement pour l'Industrie Nationale, vol. 131, no. 2, Mar.-Apr. 1919, pp. 299-328, 29 figs. Based on the Taylor system.

Weighing and Packing

Weighing and Packing by Machinery, Gilbert Balkan. Commercial America, vol. 15, no. 11, May 1919, pp. 41-45, 4 figs. Automatic weighing and packing illustrated by continuous operation applied to flour.

FINANCE AND COST

Appraisal

Advantages of the Engineering Appraisal, Charles W. McKay. Textile World Jl., vol. 55, no. 20, May 17, 1919, pp. 43-45. Discussion of federal tax problems of textile executives.

Appraising and Cost Finding, William F. Worcester. Concrete Age, vol. 30, no. 1, Apr. 1919, pp. 14-16. Address delivered before Am. Concrete Pipe Assn.

Costkeeping System

Manufacturing Non-Ferrous Metal Articles. Iron Age, vol. 103, no. 19, May 8, 1919, pp. 1209-1214, 10 figs. Annealing and pickling machinery and automatic safety devices in plant of Bridgeport Metal Goods Mfg. Co. also costkeeping system.

Costing as Applied to General Engineering, Chas. E. Lewton. Eng. & Indus. Management, vol. 1, no. 10, Apr. 17, 1919, pp. 310-317, 15 figs. Scheme in vogue at general engineering establishment is laid out with considerations on procedure adopted in commercial inspection, labor cost and allocation of predetermined establishment expenses to job; iron foundry costs; material costs and determining establishment expenses.

INSPECTION

Equipment, Inspection and Record

Demobilizing Equipment of Spruce Production Division. Eng. News-Rec., vol. 82, no. 20, May 15, 1919, pp. 967-968, 4 figs. System of inspecting and recording which is said to keep order among 4800 classifications.

Materials Before Acceptance

Inspection of Materials Before Acceptance, Emmanuel Mavaut. Contract Rec., vol. 33, no. 18, Apr. 30, 1919, pp. 417-419. Instances of failures caused by neglect to have concrete, sand and stone properly tested for quality before use.

LABOR

Convict Labor

Convict Labor on Highway Work; Organization, Administration, Camps and Cost Data. Good Roads, vol. 17, no. 18, May 3, 1919, pp. 189-190, 2 figs. Committee report presented at Convention of Am. Road Builders' Assn.

Fatigue, Industrial

Industrial Efficiency from the Psychological Standpoint—II, Chas. S. Myers. Eng. & Indus. Management, vol. 1, no. 12, May 1, 1919, pp. 359-360, 5 figs. Experiments with Kräpelin's ergograph. Distinction is established between muscular fatigue arising from excessive activity, producing clogging of physiological mechanism with products of that activity, and fatigue due to exhaustion of living substance of the muscles. Lecture delivered before Imperial College of Science & Technology.

Industrial Disputes

Organization in the Settlement of Industrial Disputes, V. Everit Macy. Eng. & Min. Jl., vol. 107, no. 19, May 10, 1919, pp. 825-828. Emphasizes that labor problem is merely a human problem and unless similar methods are employed in dealing with it as have been found effective with other human problems, maximum production and industrial peace can not be realized.

Industrial Relations

The Status of Industrial Relations, L. P. Alford. Mech. Eng., vol. 41, no. 6, June 1919, pp. 513-516 & 556. Present aspect of labor and employment problems is held to be similar to that presented by these problems immediately after civil war; situation, however, is considered as greatly amplified now. Suggestions to meet present emergency are made.

Industrial Efficiency from the Psychological Standpoint—I, Charles E. Myers. Eng. & Indus. Management, vol. 1, no. 2, Apr. 24, 1919, pp. 332-336, 6 figs. Improving mechanical conditions and sympathetic understanding of standpoint of others are considered far more important factors in determining industrial efficiency than capital or labor.

Industrial Co-operation, Charles P. Steinmetz. Am. Mach., vol. 50, no. 19, May 8, 1919, pp. 893-894. Merging capital and labor interests in one advocated as only way to meet present industrial requirements.

Labor Turnover

Reducing the Labor Turnover, W. C. Nisbet. Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 265-268. Discusses advantages of applying employment department idea to railroad shops.

Modern Industrial Plants—VI-b, George C. Nimmons. Architectural Rec., vol. 45, no. 5, May 1919, pp. 450-470, 20 figs. Excessive turnover of labor and influence of employees' welfare work on reducing it. Conditions in various plants are quoted.

Night Work

Medical Argument Against Night Work, Especially for Women Employees, Emery R. Hayhurst. Am. Jl. of Public Health, vol. 9, no. 5, May 1919, pp. 367-368. How night work emphasizes intrinsic factors which bring about chronic fatigue.

Profit Sharing

Willys Profit-Sharing Plan on 50-50 Basis, J. Edward Schipper. Automotive Industries, vol. 11, no. 18, May 1, 1919, pp. 942-944. Provides for division of profits over and above amounts reserved for interest upon capital on a 50-50 basis between workers and employers.

How to Compass Industrial Coöperation, Charles P. Steinmetz. Coal Age, vol. 15, no. 20, May 15, 1919, pp. 904-906. Proposes to give labor dividends based on wages paid and on the amount of excess profits above a certain percentage, the gross returns to labor being made equal to the excess profits allotted capital.

Wages

Uniform Wages for Workmen. Contract Rec., vol. 33, no. 18, Apr. 30, 1919, pp. 403-406, 5 figs. Assn. of Montreal Building and Construction Industries reported attempting to secure fixed wages and eliminate sub-contract abuses.

Welfare Work

Welfare Work for Employees in Industrial Establishments in the United States. U. S. Dept. Labor, Bur. Labor Statistics, Bul. no. 250, Feb. 1919, 139 pp., 40 figs. Fieldwork of investigation extended over period of twelve months in 1916 and 1917 and 31 states were visited in connection with study.

Women

Female Labour on Line Construction Work J. B. Taylor. Post Office Elec. Engrs. Jl., vol 12, part 1, Apr. 1919, pp. 26-31, 6 figs. Although work was hard, and meant exposure to all kinds of weather, experiment is reported as successful.

Women in Electrical Work. Elec. Eng., vol 53, no. 1, Jan. 1919, pp. 11-13. British meth

Let us solve Your Problem

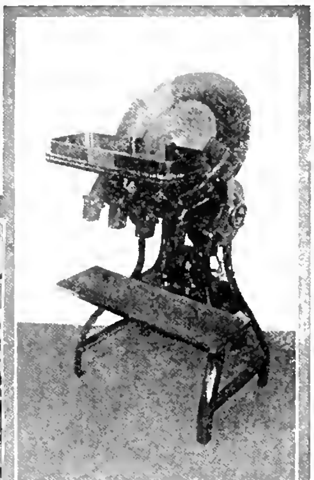
Our Model Room—

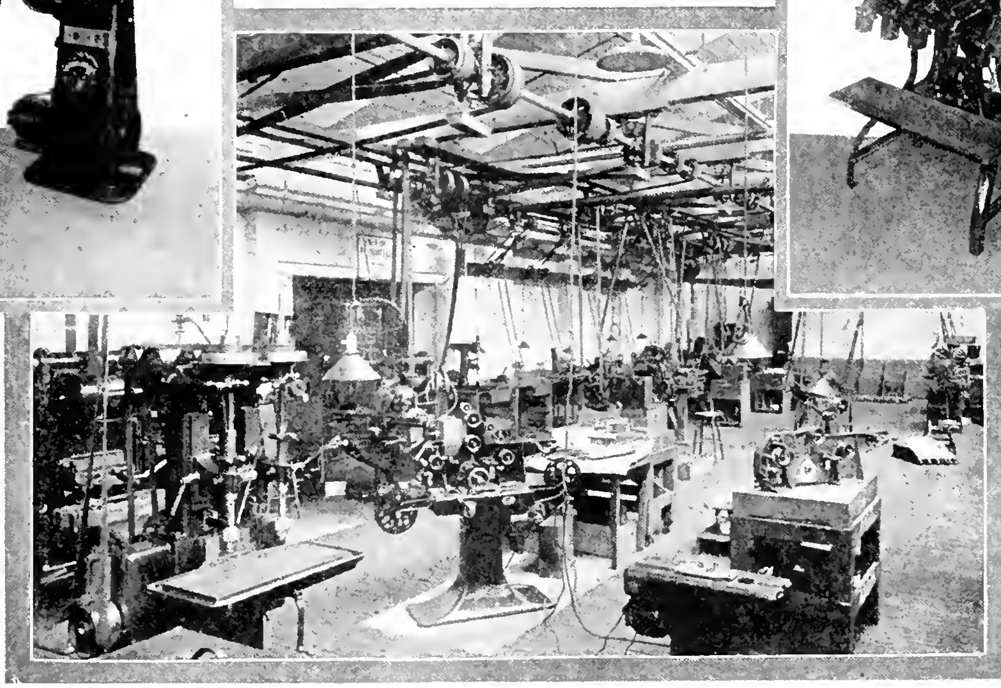
where *perfection* is assured and *accuracy* maintained.

Here is the department where all special machinery is tried out and perfected—here is where your special part is measured and tested—actual production begins here and assures perfection in the finished article. This is part of S. A. S. Service.

With our great facilities, thoroughly up-to-date equipment and our large force of skilled mechanics we are prepared to develop, perfect and produce your special intricate machine or unusual special part.

The two machines illustrated in the inserts are two of many that have been developed and perfected in our laboratories and are now being produced in our shops.





Get the benefit of this expert service

In knowledge of experience, completeness of equipment, superiority in service, and in everything that goes to form the basic foundation for developing, perfecting and producing your special work, we believe we can proclaim pre-eminence.

A complete service is offered—

to work with you and for you—from designing to finishing—whether you need a simple part of accurate measurement or an intricate mechanical device that must work accurately—we can do it and do it right—and deliver on time.

This is the fourth of a series of advertisements showing our plant, our methods and the work we are doing—Our tool room in the next issue.

We want to tell you more about the work we do and how we can help you. Better write us to-day.

SLOCUM, AVRAM & SLOCUM
LABORATORIES, Inc.

Production Plant: NEWARK, N.J. *New York Office*: Woolworth Bldg., N.Y.

Special Machinery QUANTITY PRODUCTION Jigs, Fixtures and Gages

SLOCUM-AVRAM-SLOCUM MANAGEMENT

ods for training workers in war industries. From bul. issued by U. S. Dept. Labor.

Women as Factory Inspectors. Eng. & Indus. Management, vol. 1, no. 12, May 1, 1919, pp. 368-369. Duties of women in the capacity of assistant factory inspectors in several German states, notably Bavaria and Baden. From Technik & Wirtschaft.

See also MARINE ENGINEERING, Ships (Merchant Shipbuilding.)

LEGAL

Compensation

Compensation for Occupational Diseases. Riley M. Little. U. S. Dept. Labor, Bur. Labor Statistics, bul. 248, Mar. 1919, pp. 251-257 and (discussion) pp. 258-268. Contends that hazards of industry ought to be borne by society as a whole and not by individual workingman.

LIGHTING

Shop Lighting

Improved Methods of Shop Lighting. Power Plant Engr., vol. 23, no. 10, May 15, 1919, pp. 457-459, 5 figs. Comparison of general and localized system of illumination.

Wall-Box Illumination

Lighting Without Hanging Ceiling Fixtures. J. L. Stair. Elec. Jl., vol. 16, no. 5, May 1919, pp. 183-187, 14 figs. Examples of wall box or wall pocket method of illumination.

See also ELECTRICAL ENGINEERING, Lighting and Lamp Manufacture (Lighting Codes.)

RECONSTRUCTION

Financial Conditions

Some of Our Post-War Problems. Francis B. Sisson. Am. Mach., vol. 50, no. 20, May 15, 1919, pp. 935-937. Concerning particularly financial conditions resulting from war. Address before Indus. Conference of N. Y. Business Publishers' Assn.

Foreign Trade

Reconstruction Days. Metal Indus., vol. 17, no. 5, May 1919, pp. 207-210. Analysis of present business conditions and forecast of future of foreign trade.

Problems of Our Foreign Trade. G. A. O'Reilly. Am. Mach., vol. 50, no. 19, May 8, 1919, pp. 891-893. Address before Editorial Conference of N. Y. Business Publishers' Assn.

Foreign Trade Policy

The Stabilizing Effect on American Industry of a Definite Foreign-Trade Policy. James W. Hook. Am. Mach., vol. 50, no. 20, May 15, 1919, pp. 938-939. Address delivered before Sixth Nat. Foreign Trade Convention.

Industrial Democracy

Industrial Democracy. Charles A. Eaton. Am. Mach., vol. 50, no. 20, May 15, 1919, pp. 933-935. Address before Indus. Conference of N. Y. Business Publishers' Assn.

Wage Problems

After War Problems. W. L. Hitchens. Machy. Market, nos. 964 & 965, Apr. 25 & May 2, 1919, pp. 19-20 and 19-20. Wage problem in industry. Paper read before Roy. Soc. Arts.

SAFETY ENGINEERING

Accident Prevention

Safety from the Standpoint of Industrial Efficiency. C. W. Price. Official Proc. Ry. Club of Pittsburgh, vol. 18, no. 3, Feb. 27, 1919, pp. 58-71 and (discussion) pp. 71-79. Accident prevention as common ground on which employers and employees can meet, with mutual benefit as result.

Accidents

Comparison of Industrial with Military Casualties. I. M. Rubinow. U. S. Dept. Labor, Bur. Labor Statistics, bul. 248, Mar. 1919, pp. 217-225. Concludes that in peaceful times industrial life creates as many handicapped persons as would an army of 1,000,000 soldiers fighting on the battlefields of Europe.

Some Showing from Accident Records. Lucian W. Chaney. U. S. Dept. Labor, Bur. Statistics, bul. 248, Mar. 1919, pp. 30-37. Statistics of Bur. of Labor including causes of accidents and nature of injuries described as indicating that 58 per cent of accidents could have been prevented by adequate engineering provisions.

Shipbuilding Accidents. Eng. & Indus. Management, vol. 1, no. 12, May 1, 1919, pp. 379-381. Dangers to which workmen are subjected in a shipyard and how these may be minimized or eliminated.

Fire Fighting

Fire Engines and Effective Fire Fighting. Charles H. Fox. Mech. Eng., vol. 41, no. 6, June 1919, pp. 503-505. Essentials of effective fire fighting and their relation to fire engines as viewed by writer who believes that importance of methods employed in fire fighting is often underestimated by both laymen and engineers.

Fire Prevention

Fire Prevention in the Metal Trades—I. R. E. Swearingen. Metal Trades, vol. 10, no. 5, May 1919, pp. 213-216. A clean, well-managed plant is considered not only a safer risk, but a healthier and more satisfactory place to work in and of wholesome effect on the working force.

The Saskatchewan Fire Prevention Act and the Methods of Its Administration. Arthur E. Fisher. Quarterly of the Nat. Fire Protection Assn., vol. 12, no. 4, Apr. 1919, pp. 334-342. One section appoints local assistants to Fire Commissioner in every place, with practically all powers granted to Commission.

Mechanical Safeguards

Mechanical Safeguards. David S. Beyer. U. S. Dept. Labor, Bur. Labor Statistics, bul. 248, Mar. 1919, pp. 16-26. Emphasizes importance of mechanical guarding in addition to safety education for prevention of accidents. Desirability of standardizing mechanical guards is advocated and an account of work done in this direction by Standardization Committee of Nat. Safety Organization is mentioned.

TRANSPORTATION

Electric Trucks and Tractors

The Field for Industrial Electric Trucks and Tractors. Elec. Rev., vol. 74, no. 20, May 17, 1919, pp. 791-795, 7 figs. Examples of their application in various industries. (First article.)

Electric Vehicles. C. Tunstill Opperman. Surveyor, vol. 55, no. 1421, Apr. 11, 1919, pp. 271-272. Their reliability and economy on short journeys.

Truck Delivery Costs

Cost of Highway Concrete Delivered Wet by Trucks. Eng. News-Rec., vol. 82, no. 18, May 1, 1919, pp. 870-872, 3 figs. Delivery of wet concrete from central crushing and mixing plant to road surface, by motor trucks, over hauls ranging from 1/4 mile to 4 miles reported as being satisfactorily accomplished by Maryland State Road Commission.

See also RAILROAD ENGINEERING, Operation and Management (Accident Prevention), Safety and Signaling Systems; AERONAUTICS, Production (Fire Hazard); MINING ENGINEERING, Mines and Mining (Cartridges, Safety; Lamps, Safety.)

Electrical Engineering

ELECTRODEPOSITION

Galvanizing Plant

Planning and Operating a Galvanizing Plant. E. P. Later. Foundry, vol. 47, no. 7, May 15, 1919, pp. 289-291, 5 figs. Analysis of temperature factors and difficulties; remarks on choice of kettles, tanks and cleaning equipment.

ELECTROPHYSICS

Cables, Aerial

General Property of Aerial Cables (Sur une propriété très générale des câbles servant aux transport aériens). G. Leinekugel le Cocq. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 15, Apr. 14, 1919, pp. 761-764, 1 fig. Portion of cable between two suspension points considered as beam and deflections at various points determined in terms of horizontal tension at extremities and integral of bending moments to left of section.

Current Rectification by Voltameter

Direct Current Generation by Applying Alternating Electromotive Force to Voltameter with Platinum Electrodes (Sur la production d'un courant continu par application d'une force électromotrice alternative à un voltamètre a électrodes de platine). P. Vaillant. Revue Générale de l'Electricité, vol. 5, no. 16, Apr. 1919, pp. 593-594. From Comptes rendus des séances de l'Académie des Sciences, vol. 168, Mar. 31, 1919, pp. 687-689.

Emission of Electricity from Incandescent Bodies

Emission of Electricity from Incandescent Bodies (L'émission d'électricité par les corps incandescents). A. Boutaric. Revue Générale des Sciences, vol. 30, no. 7, Apr. 15, 1919, pp. 198-211, 17 figs. Its application in construction of Fleming valve, audion and tubes acting by electronic discharges. The theory of operation of these apparatus is outlined and a mathematical theory of the operation of vacuum three-electrode tubes is presented. Second article.

Oscillations, Maintained

Electrotechnical Analogy of Maintained Oscillations (Sur une analogie électrotechnique des oscillations entretenues). Paul Janet. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 15, Apr. 14, 1919, pp. 764-766. Anology between maintained oscillations used in wireless telegraphy and reversing motion of separately excited motor when fed by series generator and running on no load.

FURNACES

Booth-Hall Electric Furnace

The Booth-Hall Electric Furnace. W. K. Booth. Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, p. 617, 3 figs., also Can. Machy., vol. 21, no. 18, May 1, 1919, pp. 430-433, 7 figs. This conducting-hearth electric furnace has an auxiliary electrode for starting and automatic control. Paper read before Iron & Steel Inst., and Instn. Elec. Engrs. at joint meeting.

Control of Temperature

Metal Melting in Electric Furnaces. E. F. Collins. Metal Indus., vol. 17, no. 5, May 1919, pp. 221-224, 3 figs. Some characteristics of the furnace installation treated are control of temperature of heat-generating source and uniform distribution of heat generated.

Héroult Furnace

Work of the Electric Furnace. Elec. Eng., vol. 52, no. 5, Nov. 1918, pp. 12-13, 4 figs. Installation at plant of Driver-Harris Co., Harrison, N. J. Furnace is of Héroult arc type, featured with automatic regulation; it has capacity of two tons.

Non-Ferrous Metal Melting

Electric Furnace for Melting Nonferrous Metals—I. Edgar F. Collins. Foundry, vol. 47, no. 7, May 15, 1919, pp. 284-288, 6 figs. Diagram illustrating principles of carbon-electrode type of furnace. Notes on continuity and dependability of service in melting brass commercially.

Melting of Non-Ferrous Metals and Alloys. Elec. World, vol. 73, no. 21, May 24, 1919, pp. 1110-1114, 5 figs. Data presented to show that saving of 100 per cent or more may be expected from electrical method in brass-melting industry.

Sahlin Furnace

A New Type of Electric Furnace. Axel Sahlin. Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, p. 618, 2 figs. Built as circular ladle with contracted top and dished bottom. Paper read at joint meeting of Iron & Steel Inst. and Instn. Elec. Engrs.

Steel-Furnace Practice

Pointers on Electric Steel Furnace Practice. H. E. Diller. Foundry, vol. 47, no. 6, May 1, 1919, pp. 239-242, 6 figs. Data on arc-type furnaces based on research work conducted by writer and his experience in various foundries.

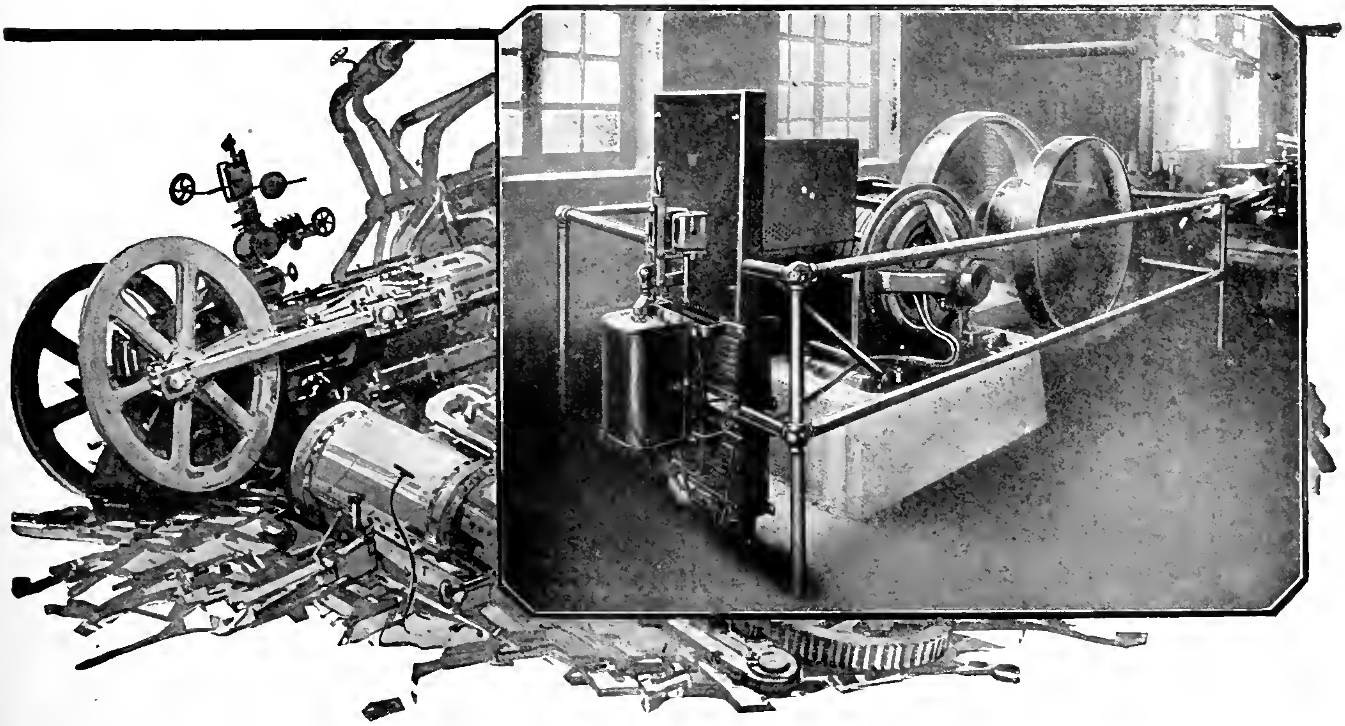
Steel-Furnace Progress

Electrical Apparatus Development. Elec. World, vol. 73, no. 21, May 24, 1919, pp. 1102-1105, 4 figs. Growth of electric steel furnace indicated by mentioning that while in July, 1913, there were only about 20 such furnaces in the U. S. A., at the end of 1918 there was a total of 287.

Electric Furnaces. W. E. Moore. Jl. Engrs. Club of St. Louis, vol. 4, no. 2, Mar.-Apr. 1919, pp. 166-183, 4 figs. History of development with remarks on quantity production. Arc-type furnace is considered as best suited type for foundry work.

Developments in Electric Iron & Steel Furnaces. J. Bibby. Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 611-617, 23 figs. Remarks confined to development in manufacture of iron and steel by means of electric furnaces. It is emphasized that it is important for electrical engineers to grasp requirements of metallurgists and to be acquainted with working conditions of blast furnaces and steel foundries. Paper read at joint meeting of Iron & Steel Inst. and Instn. Elec. Engrs.

The present and future competitive conditions compel every manufacturer to seriously consider the wonderful advantages, efficiencies and economies possible with the use of electrical equipment.



One G-E Motor-Driven Compressor Supersedes Two Steam Engines

THIS one little 50 horsepower G-E motor is being used to drive an air compressor which is doing the work previously done by two steam-driven compressors. It furnishes full compression for every air tool in the quarry — at Penn Allen Cement Co.

This is just another example of where G-E engineering service has been of great value to the customer.

The next point is — is your mill completely electrified? If not, you are not realizing full value on your principal investment.

General Electric Company

General Office Schenectady, N.Y.

43-260

Steel Furnaces

Large Electric Steel-Melting Furnaces, Victor Stobie. Iron & Coal Trades Rev., vol. 98, no. 2671, May 2, 1919, pp. 618-621, 8 figs. Suggested connections for various sizes. Paper read at joint meeting of Iron & Steel Inst. and Instn. Elec. Engrs.

GENERATING STATIONS

Centralization of Electric Power

The Significance and the Opportunities of the Central Station Industry, R. F. Schuckardt. Elec. Jl., vol. 16, no. 5, May 1919, pp. 166-168. Believing centralization of electric power will come eventually writer urges planning present extensions so that in due time interconnection can be carried out most economically.

The Primaries of Today, the Secondaries of Tomorrow, W. S. Murray. Elec. Jl., vol. 16, no. 5, May 1919, pp. 168-170. Advantages of centralization of electric power illustrated by quoting comparative load factors of central plants and plants otherwise operated.

Eastern Companies

Promising Outlook for Eastern Companies. Elec. World, vol. 73, no. 20, May 17, 1919, pp. 984-991, 14 figs. Central-station situation outlined for several communities, notably Philadelphia, Baltimore, New Jersey and New York City.

Hydroelectric Plant, Small

Opportunities for and Data on Small Municipal Hydro-Electric Plants Wm. G. Fargo. Min. & County Eng., vol. 56, no. 5, May 1919, pp. 168-171 3 figs. Example of rating curve for determining intermediate stream flow based on several flow measurements.

Ice Making and Refrigeration

Central-Station Service for Ice Making and Refrigeration, C. J. Carlsen. Elec. Rev., vol. 74, no. 20, May 17, 1919, pp. 783-787, 6 figs. Status and growth of load in New York and Chicago indicating tendency to use synchronous motors.

Middle West

Central Station Progress in the Middle West. Elec. World, vol. 73, no. 20, May 17, 1919, pp. 1001-1006, 8 figs. Engineering development of last eighteen months.

Peat-Fired Central Station

Steam-Driven Central Station at Vasteras, Sweden (La station centrale thermo-électrique de Västerås), V. Forssblad. Génie Civil, vol. 74, no. 15, Apr 12, 1919, pp. 296-298, 3 figs. Designed to insure constant feeding of network served by hydroelectric plants. It utilizes peat available in region. From Teknisk Tidskrift.

Railway Power Station

New Railway Power Station. Southern Engr., vol. 31, no. 3, May 1919, pp. 36-39, 4 figs. Station generates 2,400 kw. at maximum rating; present equipment consists of horizontal cross-compound Nordberg-Corliss engines driving 1200 kw. direct-current generators.

Rotary Converters

An Interesting Rotary Converter Installation at Ilford. Electricity, vol. 33, no. 1185, Apr. 25, 1919, pp. 257-259, 4 figs. Inverted rotary converter with step-up transformer and rotary converter supplying continuous current at substation installed by General Electric Co., Ltd.

Totalization of Load

New Emergency Bus Feature in Brantford Hydro-Electric Station. Elec. News, vol. 28, no. 9, May 1, 1919, pp. 29-30, 3 figs. Scheme provides for totalizing load no matter which way current is fed.

Turbines

The Year's Electrical Development. Elec. Eng., vol. 53, no. 1, Jan. 1919, pp. 23-28, 2 figs. Concerning particularly turbine unit installations.

See also MARINE ENGINEERING, Ships (Electric Propulsion).

GENERATORS AND MOTORS

Converters

Adapting Automatic Control to Motor Started Converters, R. J. Wensley. Elec. Ry. Jl., vol. 53, no. 20, May 17, 1919, pp. 948-951, 6 figs. Control developed by Westinghouse Electric & Manufacturing Co. Principle is same as that of automatic control of self starting machines.

High-Frequency Machines

Regulation of High-Frequency Machines (Sur les machines à haute fréquence et leur réglage), J. Bethenod. Bulletin de la Société Française des Electriciens, vol. 9, no. 78, Mar. 1919, pp. 161-176, 2 figs. Technical study. Formulæ derived both in case of a single machine and when two machines are coupled.

Induction Motors

Three-Phase Currents in Mining Work. Elec. Eng., vol. 52, no. 6, Dec. 1918, pp. 18-20, 2 figs. Simplicity of squirrel cage for induction motor, absence of commutator in all forms of induction motors, and convenience with which large amounts of power can be transmitted over long distances, and their pressures converted to any figure that may be desired at the points of consumption, are believed to have given three-phase currents preference over continuous-current service.

Light-Weight Generators

Light Weight Electric Generating Sets. Engineering, vol. 107, no. 2782, Apr. 25, 1919, pp. 531-533, 9 figs. Sets made by A. Lyon & Wrench, Ltd., Willesden, London. These have been used by Admiralty, War Office and Air Ministry, supplying power for daylight signaling, X-ray apparatus, battery charging, landing lights for aerodromes and general lighting of huts, dugouts, etc.

Radiotelephony, Generators for

Dynamotors and Wind-Driven Generators for Radiotelephony, R. G. Thompson. Elec. Jl., vol. 16, no. 5, May 1919, pp. 205-210, 12 figs. Single-armature, double commutator, bipolar, ball-bearing, totally-enclosed direct-current machine, 5 in. in diameter and 8.5 in. long, weighing approximately 15 lb.

Synchronous Motors

Synchronous Motor Characteristics—II, Theo. Schou. Elec. World, vol. 73, no. 18, May 3, 1919, pp. 880-883, 12 figs. Compound squirrel-cage winding developed for pulling into step synchronous motors carrying full load.

Utilizing the Time Characteristics of Alternating Current, Henry E. Warren. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 5, May 1919, pp. 629-643, 10 figs. Small self-starting synchronous motor devised for driving timing devices such as clocks, graphic-instrument movements, time recorders, etc., directly from lighting circuits.

Winding

Rewinding 12,000 Kw. Turbo Generator Field. Elec. World, vol. 73, no. 18, May 3, 1919, pp. 893-894, 3 figs. Work performed on insulation and damaged coils.

See also MECHANICAL ENGINEERING, Power Plants (Turbo Generators).

IGNITION APPARATUS

Magnetos

Sparking Power of Magnetos, Harry F. Geist. Automotive Industries, vol. 11, no. 18, May 1, 1919, pp. 949-953, 8 figs. Oscillograms showing electromotive force across contact points of breaker and current flowing in ignition circuit for five different points of interruption.

Experiments on the High-Tension Magneto—II, Norman Campbell. Lond. Edinburgh, and Dublin Phil. Mag., vol. 37, no. 220, Apr. 1919, pp. 372-396, 16 figs. Object of experiments was to discover how far the relation between peak potential, primary capacity, and coupling of circuits, which is predicted by theory, is found in experiment. (Continued.)

Spark Plugs

The Operation and Design of Sparking Plugs, H. Warren. Automobile Engr., vol. 9, no. 123, Feb. 1919, pp. 53-63, 14 figs. Actual ignition of explosive charge in engine cylinder is particular case with which writer deals, attention being confined to physical conditions under which ignition is effected and operation and design of sparking plugs. (To be concluded.)

LIGHTING AND LAMP MANUFACTURE

Lighting Codes

Present Status of Industrial Lighting Codes, G. H. Stickney. Am. Architect, vol. 115, no. 2264, May 14, 1919, pp. 694-698. In four states and in several establishments industrial lighting codes have been adopted for the protection of workers from accidents and eye strain. Specifications deal with intensity, glare limits and distribution. Various texts are discussed and suggestions are offered. (To be continued.) Paper presented at joint meeting of Am. Inst. Elec. Engrs. and Illuminating Eng. Soc.

Motion-Picture Projection

Mazda C Lamps for Motion Picture Projection, A. R. Dennington. Elec. Jl., vol. 16, no. 5, May 1919, pp. 201-204, 6 figs. Westinghouse equipment.

See also ORGANIZATION AND MANAGEMENT, Lighting.

MEASUREMENTS AND TESTS

Capacity and Capacitance

Measuring Capacity in a Three-Phase Armored Cable and Evaluation of the Current of Capacitance (Mesure de la capacité dans les câbles armés triphasés en vue de l'évaluation du courant de capacitance) Raymond Bouzon. Revue Générale de l' Electricité, vol. 5, no. 18, May 3, 1919, pp. 651-653, 4 figs. Theory and formulæ.

Electrostatic Glow Meter

The Electrostatic Glow Meter, R. J. Wensley. Elec. Jl., vol. 16, no. 5, May 1919, p. 228, 4 figs. For indicating in high tension switching stations presence of potential, grounded phase or synchronism between two separate high-tension lines.

Insulator Testing

Western Practice in the Testing of Insulators. Elec. Rev., vol. 74, no. 19, May 10, 1919, pp. 741-743. Report of Insulator Committee presented before Pacific Coast Section N.E.L.A. Covers tests used and adopted by various operating companies of Pacific slope together with description of equipment and limitations of the various methods.

Insulating Materials, Dr. Bultemann. Elecn., vol. 82, no. 17, Apr. 25, 1919, pp. 491-492. Their uses, breakdown voltages and preparation. (To be concluded.) From Gummi Zeitung, nos. 43, 45, 46, 47, 48, 1918.

Methods of Measuring Conductivity of Insulating Materials at High Temperatures, F. B. Silsbee and R. K. Honaman. Jl. Wash. Acad. Sciences, vol. 9, no. 9, May 4, 1919, pp. 252-266, 4 figs. Results obtained by use of alternating-current method on a number of types of samples. Figures show variation in resistance but similarity in constant b, which is a measure of temperature coefficient of their resistance.

Magnets, Permanent

Note on the Testing of Permanent Magnets, J. D. Morgan. Engineering, vol. 107, no. 2782, Apr. 25, 1919, pp. 525-526, 5 figs. Writer feels that it is undesirable to depart from established practice of specifying in terms of B_{rem} and H_c, but he suggests additional test for determining maximum B H product.

Temperature Indicators for Alternators

Temperature Indicators for Alternators, S. L. Henderson. Elec. Jl., vol. 16, no. 5, May 1919, pp. 193-196 11 figs. Of exploring coil and thermo-couple methods while both are admitted to give satisfactory results still the latter is believed to give results nearer maximum measurable temperature because it is said it indicates temperature at a spot while exploring coil gives average temperature over its length.

Voltages, High

Electrastatic Apparatus for Measuring Very High Voltages (Technische elektrostatische Apparate zur Messung sehr hoher Spannungen) A. Imhof. Schweiz. Elektrotechnischer Verein, Bul. no. 3, vol. 10 Mar. 1919 pp. 47-52, 7 figs. Apparatus described by writer is based on principle whereby only part of the voltage passes through "measuring system" (2 electrodes, one stationary the other movable), the remainder of the voltage passing through a series condenser.

POWER APPLICATIONS

Filtration Plant

Electric Filtration Plant, R. U. Steelquist. Jl. Electricity, vol. 42, no. 9, May 1, 1919, pp. 427-438 5 figs. Electrically pumped, electrically filtered water supply of Albany, Ore.

Heat Treatment

How the Power House Aids the Forge, L. F. Johnson. Iron Trade Rev., vol. 64, no. 19, May 8, 1919, pp. 1221-1226, 12 figs. How electricity is used for heat-treating guns and other heavy forgings by Inland Ordnance Co.

Heating

Heating Liquids by Electricity—the Past, the Present and the Future, H. O. Swoboda. Proc. Engrs. Soc. Western Pa., vol. 34, no. 8, Nov. 1918, pp. 537-571 and (discussion) pp. 572-574, 26 figs. Examination of several electric circulation water heaters, notably in the West, leads writer to believe that with the establishment of high-power central stations electric heating devices offer sufficient advantages to predict their general adoption.

Plate Mills

Electrically-Driven Plate Mills, G. W. Haney. Elec. Jl., vol. 16, no. 5, May 1919, pp. 188-192, 14 figs. Of Brier Hill Steel Co. Two 66,000 volt lines connect to a main and auxiliary bus which is supported in structural work by suspension insulators; bus arrangement allows flexibility in switching to permit any piece of apparatus to be cut out of circuit.

Quarrying

Quarrying and Working Stone by Electricity. Elec. Eng., vol. 53, no. 3, March 1919, pp. 105-107. Applications in Belgium, U. S. A. and Great Britain.

POWER GENERATION

Hydroelectric Plants

See Power Generation, MECHANICAL ENGINEERING.

See also MARINE ENGINEERING, Auxiliary Machinery (Electrical Auxiliaries.)

STANDARDS

Motor Rating

The Continuous-Rated Motor and its Application. L. F. Adams. Elec. World, vol. 73, no. 19, May 10, 1919, pp. 936-939. Reasons for adopting 50 deg. temperature rise for motor rating. Efficiency of economical use of motor material as affected by development of motor design and amelioration of hot spots.

Voltage Standardization

Standardization of Voltage in Switzerland (Zur Frage der Vereinheitlichung der Betriebsspannungen in der Schweiz). H. Schweiz. Elektrotechnischer Verein, Bul. no. 3, vol. 10, Mar. 1919, pp. 43-47. Normal voltage to be fixed on basis of voltage most generally employed lately. Figures presented show that 90 per cent. of current systems used and motors installed in 1918 were of the three-phase alternating-current type.

STORAGE BATTERIES

Charging

Charging Storage Batteries under Constant Voltage (Charge des accumulateurs sous tension constante), Fernand T'sas. Société Belge des Electriciens, vol. 33, Jan.-Mar. 1919, pp. 41-43, 2 figs. Scheme of connections.

See also RAILROAD ENGINEERING, Electric Railroads (Battery Locomotives.)

TELEGRAPHY AND TELEPHONY, RADIO

Airplane Telephone Sets

Development of Airplane Radiotelephone Set. H. M. Stoller. Elec. Jl., vol. 16, no. 5, May 1919, pp. 211-214, 10 figs. Transmitting circuit consists of two three-element vacuum tubes connected to an input transformer operated by a microphone telephone transmitter. S C R-68 set.

Nomenclature

Nomenclature in Wireless Telegraphy—II. W. H. Eccles. Elecn., vol. 82, no. 17, Apr. 25, 1919, pp. 499-500. Ionic tubes used in radio work. (To be concluded.)

Static Interference

Static Interference and the Wireless. Roy A. Weagant. Elec. Eng., vol. 53, no. 3, Mar. 1919, pp. 117-119, 1 fig. Writer states that other investigators have considered characteristics of signal wave and static wave to be the same. He holds an opposite view and claims to have discovered the nature of the difference and on this knowledge to have based his invention for preventing static interference. Paper read before Joint Meeting of Inst. Radio Engrs. and N. Y. Elec. Soc.

Transatlantic Reception

Transatlantic Radio Reception. Charles A. Culver. Jl. Franklin Inst., vol. 187, no. 5, May 1919, pp. 525-579, 13 figs. In order to provide for transatlantic communication in event of failure of cables, representatives of Navy and War Departments decided to establish six experimental radio stations at Army posts. Conditions, personnel equipment and results are discussed.

Valves, Ionic

Three-Electrode Lamp Valve (La lampe-valve à trois électrodes), C. Gutton. Revue Générale de l'Electricité, vol. 5, no. 17, Apr. 26, 1919, pp. 629-640, 16 figs. Work undertaken in the laboratories of the Radiotélégraphie Militaire.

See also AERONAUTICS, Auxiliary Service (Telephone Apparatus, Radio.)

TELEGRAPHY AND TELEPHONY, WIRE

Field Telephones

Field Telephone of the German Army (L'appareil téléphonique de campagne de l'armée allemande). Annales des Postes, Télégraphes et Téléphones, vol. 8, no. 1, 1919, pp. 94-102, 6 figs. Electrical scheme and connection for apparatus serving two lines.

Fullerphone

The Fullerphone. A. C. Fuller. Elecn., vol. 82, no. 19, May 9, 1919, pp. 536-538, 5 figs.; also Engineer, vol. 127, no. 3301, Apr. 4, 1919, p. 435, 5 figs. Among advantages claimed for its application to civil telegraphy are saving of battery power, simplicity of wiring and manipulation of instruments, covering long distances without relaying and reduction to minimum of maintenance of lines. Paper read before Instn. Elec. Engrs.

Marine Telephone, Anti-Noise

A Successful "Anti-Noise" Marine Telephone. Pac. Mar. Rev., vol. 16, no. 5, May 1919, pp. 121-123, 3 figs. Use of both ears is permitted by special construction of hand set.

Protection of Lines

Systems of Protecting Telephone Lines against Falling on Trolley Wires (Los sistemas de protección contra la caída de los hilos telefónicos sobre las líneas aéreas de los tranvías eléctricos), Eug. Aigouy. Energía Eléctrica, vol. 21, no. 5, Mar. 10, 1919, pp. 58-61. Systems employed in Norway, Switzerland, Russia and Spain. (Concluded.)

Telephone Receivers

On the Determination of the Electrical and Acoustic Characteristics of Telephone Receivers. Louis V. King. Jl. Franklin Inst., vol. 187, no. 5, May 1919, pp. 611-625, 5 figs. Theoretical aspect presented from viewpoint of possible improvements.

Unification of Telegraph and Telephone Facilities

Unification of Telegraph and Telephone Facilities in the St. Louis-East St. Louis Terminal District. Frederick E. Bentley. Official Proc. St. Louis Ry. Club, vol. 23, no. 11, Mar. 14, 1919, pp. 236-246. Suggests unification plan.

TRANSFORMERS, CONVERTERS, FREQUENCY CHANGERS

Insulation

The Insulation of Distribution Transformers. A. C. Farmer. Elec. Jl., vol. 16, no. 5, May 1919, pp. 223-227, 15 figs. Advantages claimed for treatment at Westinghouse plant, which reduced windings to solid mass of copper and insulation.

Parallel Connections of Transformers

Parallel Connection of Transformers Fed by One System or by Two Systems (La pratique de la mise en parallèle des transformateurs alimentés par le même réseau ou par deux réseaux), B. Guerschinovitch. Industrie, Electrique, vol. 28, no. 644, Apr. 25, 1919, pp. 148-153, 13 figs. Possibility of realizing delta or star connection in cases when both primary and secondary windings are at high tension, conditions being assumed to be theoretically perfect as regards connection of phases, etc.

Phase Transformation

Essentials of Transformer Practice—XXII. E. G. Reed. Elec. Jl. vol. 16, no. 5, May 1919, pp. 216-218, 5 figs. Phase transformation with autotransformers.

Scott Transformer Connections

Intensity and Maximum Power of Scott System of Connecting Transformers (Le calcul des intensités dans les transformateurs disposés suivant le montage de Scott et ses conséquences au point de vue de la puissance maximum admissible), E. Baticle. Revue Générale de l'Electricité, vol. 5, no. 17, Apr. 26, 1919, pp. 619-621, 2 figs. The two transformers are found to work under notably different conditions; consequently taking of suitable precautions is recommended.

TRANSMISSION, DISTRIBUTION, CONTROL

Circuit Protecting Devices

Circuits and Their Protecting Devices (in Japanese), M. Shibuzawa. Denki Gakkwai Zasshi, no. 369, Apr. 10, 1919.

Inductive Interference

Inductive Effects of Power Lines on Communication (in Japanese), M. Shibuzawa. Denki Gakkwai Zasshi, no. 369, Apr. 10, 1919.

Line Construction, Medium-Voltage

Construction Developments for Medium-Voltage Lines. D. F. Parrott. Elec. Rev., vol. 74, no. 18, May 3, 1919, pp. 703-708, 9 figs. Data of cost on man-hour basis. Paper read before Minnesota Electrical Assn.

Overload Relays

Overload and Reverse Power Relays. A. E. Hester. Elec. Eng., vol. 53, no. 1, Jan. 1919, pp. 17-22, 9 figs. Induction-type overload relay.

Substations

Outdoor Substations for Intercounty Development. Elec. World, vol. 73, no. 18, May 3, 1919, pp. 884-887, 10 figs. Substation through which small groups of consumers are being served from 26,400-volt circuits.

A Modern Substation. Roy R. Kime. Power Plant Eng., vol. 23, no. 10, May 15, 1919, pp. 437-440, 5 figs. Substation serving congested district in New York City. Attention is called to limitations imposed upon construction by the necessity of placing substation near center of load, among residences, where real estate is high and where quiet operation and freedom from vibration are essential.

Largest Portable Substation. Elec. Eng., vol. 52, no. 6, Dec. 1918, pp. 11-12, 3 figs. Long Island R. R. Co. emergency substation having normal capacity of 1500 kw.

Voltage Regulation

Voltage Regulation. J. Humphrey. Iron & Coal Trades Rev., vol. 98, no. 2668, Apr. 18, 1919, pp. 472-473, 6 figs. Importance of regulating voltage in collieries and other industrial concerns. Methods for securing it and description of Westinghouse system of compounding alternators, invented by Prof. Miles Walker.

WELDING

See MECHANICAL ENGINEERING, Welding (Electric Welding).

WIRING

Hotel

Electric Service in World's Largest Hotel—I. Elec. World, vol. 73, no. 19, May 10, 1919, pp. 940-943, 8 figs. Schematic diagram of feeders in riser shafts extending from basement to roof.

VARIA

Leclanche Cells

Renovation of Leclanché Porous Pots and the Re-use of the Interiors of Spent Dry Cells. W. J. Thorrowgood. Ry. Gaz., vol. 30, no. 18, May 2, 1919, pp. 763-764. Reported that old porous pots were renovated by treatment with solution of one part hydrochloric acid and five parts water. Paper read before Instn. Ry. Signal Engrs.

Statistics

Statistics of the Electrical Industry. Gas Age, vol. 43, no. 9, May 1, 1919, pp. 474-475. Reports upon central stations and street railways issued by U. S. Census Bureau.

Civil Engineering

BRIDGES

Culverts and Small Bridges

Culverts and Small Bridges. Charles D. Snead. Better Roads & Streets, vol. 9, no. 3, Mar. 1919, pp. 86-88. Examines mixing practice throughout State of Kentucky and lists what he terms faults in procedure.

Maintenance

See Painting and Maintenance below.

Military

Military Bridges Built by the English Army (Les pont-routes militaires de l'armée anglaise), R. Mechin. Génie Civil, vol. 74, no. 15, Apr. 12, 1919, pp. 285-291, 18 figs. and 2 extra plates. Construction, and erection of Inglis, Portal, Dawit and Hopkins types. Organization of engineering corps.

Painting and Maintenance

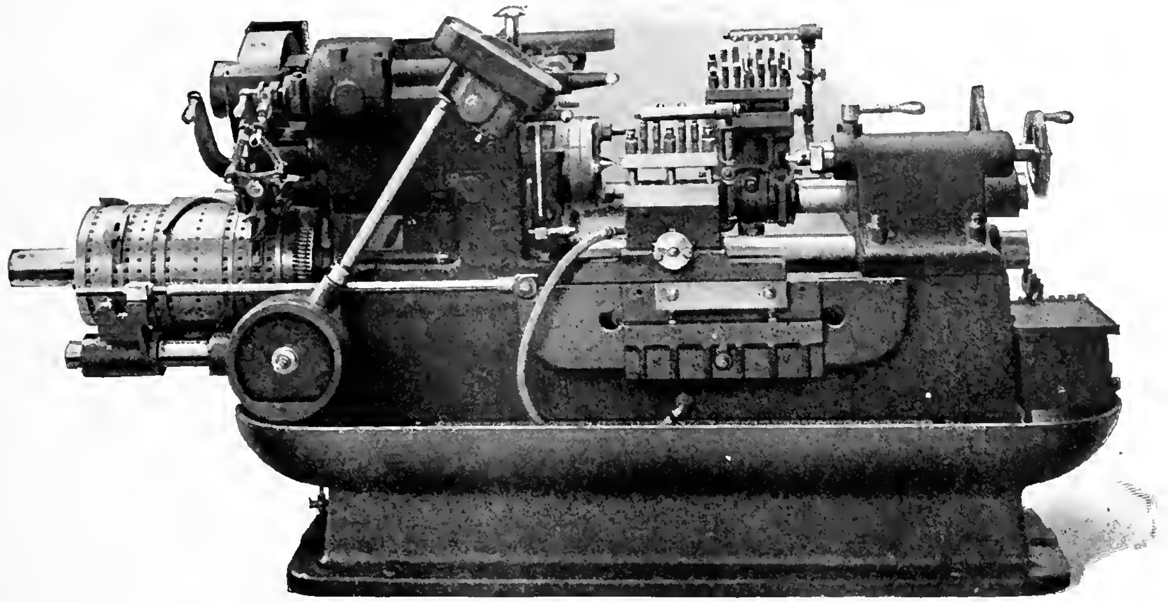
Recommended Procedure in the Painting and Maintenance of Highway Bridges. Charles D. Snead. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 171-172. Periodical inspection of structures, particularly of small culverts after very hard rain, is recommended as advisable practice.

A Survey of Electric Railway Bridge Maintenance. R. C. Cram. Elec. Ry. Jl., vol. 53, no. 20, May 17, 1919, pp. 952-959, 11 figs. Specifications of Massachusetts Public Service Commission.

Raising Bridge

Raising Allegheny River Bridge 13 Feet by Jacking. Eng. News-Rec., vol. 82, no. 18, May 1, 1919, pp 850-854, 9 figs. Increasing by 12.6 ft. the underclearance of a four-track, two-level steel structure at Pittsburgh without interruption of traffic.

The Fay Automatic Lathe



An automatic machine for simultaneous turning, facing and shouldering cuts on bar stock and centered forgings, such as pinion shafts, steering knuckles, cam shafts, etc.

An automatic machine for second operations on work held on centered arbors, such as spur and bevel gear blanks, hubs, pulleys, etc.

Designed with strength and driving power to carry all the tools, speed, and feed the work will stand under balanced cuts.

JONES & LAMSON MACHINE COMPANY

SPRINGFIELD, VERMONT, U. S. A.

109 Queen Victoria Street, London, E. C.

France, Spain and Belgium: F. Auberty & Co., 91 Rue de Maubeuge, Paris
Holland: Spliethoff, Beeuwkes & Co., Rotterdam

SEE OUR DATA IN 1918 A.S.M.E. CONDENSED CATALOGUES OF MECHANICAL EQUIPMENT

Reinforcement

Reinforcement of Bridge by Means of an Eccentric Chord. Eng. News-Rec., vol. 82, no. 19, May 8, 1919, pp. 912-914, 4 figs. Strengthening steel bridge span in Chicago without infringing on underclearing and without using falsework.

Repairs

Repairs to Bridge at Kampen, Holland (Herstellingswerken aan de brug over den Ijssel te Kampen), J. C. Pannekoek. De Ingenieur, vol. 34, no. 12, Mar. 22, 1919, pp. 204-206, 8 figs. Collision of steamer with one of the girders damaged bottom flange, plates and angles being torn away. Damaged parts were removed and actual tension on girder determined by calculation and checked by spring balance temporarily inserted.

Small Bridges

See Culverts and Small Bridges above.

Superstructure

Design of New Superstructure of Louisville Bridge with 644-Foot Riveted Span. Eng. News-Rec., vol. 82, no. 21, May 22, 1919, pp. 1007-1011, 10 figs., partly on separate plate. Replacement of Pennsylvania's historic Fink-truss bridge over Ohio River at Louisville, Ky., said to have involved design and erection under exceptional conditions.

Wilson Bridge

Wilson Bridge Combines Stone and Concrete. Contract Rec., vol. 33, no. 20, May 14, 1919, pp. 451-453, 4 figs. Six-span arch structure over river Rhône has masonry arches, cut-stone trimmings and Hennebique type concrete deck.

BUILDING AND CONSTRUCTION

Army Construction Division

The World's Biggest Building Project, Arthur J. Widmer. Jl. Engrs. Club of St. Louis, vol. 4, no. 2, Mar.-Apr. 1919, pp. 125-141. Work of the Construction Division of the army said to have involved expenditure of $1,200,000,000 for period of 18 months.

Concrete Houses

Housing Project Construction Costs, Charles F. Willis. Concrete, vol. 14, no. 5, May 1919, pp. 185-190, 14 figs. Concrete houses in groups at Tyrone, N. M.

Cottage

The Perfect Double-Flatted Cottage Dwelling, Robert Thomson. Building News, vol. 116, no. 3353, Apr. 9, 1919, pp. 212-213, 1 fig. Structural arrangement of offices housing water-using appliances and their combination with entrance lobby makes each of them independently accessible therefrom.

Stucco-Coated English Type of House. Building Age, vol. 41, no. 5, May 1919, pp. 162-163, 4 figs. Plans, elevations and cross-sections of three-story 35-ft. x 31-ft. design.

Dams

See Earthwork, Rock Excavation, etc.

Factory Production of Building Parts

Reducing Construction Costs—II, Theodore F. Laist. Am. Contractor, vol. 40, no. 19, May 10, 1919, pp. 21-22 and 35. Suggests factory production of essential structural parts of dwellings as way to offset high cost of materials.

Floors

Reducing Construction Costs, Theodore F. Laist. Am. Contractor, vol. 40, no. 18, May 3, 1919, pp. 32-34, 10 figs. Reinforced-concrete floors in apartment buildings are suggested as means of decreasing depreciation charges and eliminating loss through obsolescence.

Halifax Ocean Terminals

Reinforced Concrete Building, J. J. Macdonald. Can. Engr., vol. 36, no. 18, May 1, 1919, pp. 427-429, 1 fig. General plan of part of Halifax ocean terminals showing coach cleaning and storage yard.

Housing Projects

Notes on Grading and Planting Plans for Government Housing Projects, H. V. Hubbard. Landscape Architecture, vol. 9, no. 3, Apr. 1919, pp. 131-140. Concerning projects executed by U. S. Housing Corporation.

Competition for the Design of a Housing Scheme at Bözingen, near Biel (Wettbewerb für eine Wohnkolonie im Fuchsenried in Bözingen bei Biel). Schweizerische Bauzeitung, vol. 73, no. 7, Feb. 15, 1919, pp. 67-72, 8 figs. Specifications required 60 per cent of dwellings should have 2 bedrooms, living room, kitchen, cellar and attic; 30 per cent 3 bedroms instead of 2; and 10 per cent 4 bedrooms and in addition a separate kitchen. Schemes of six competitors and report of assessors are given with criticisms and comments.

Industrial Housing

Industrial Housing, C. W. Ruth. Stone & Webster Jl., vol. 24, no. 5, May 1919, pp. 388-392, 2 figs. Believes that the most economical structure is the five to six-room house, because it allows family to take one or two roomers and boarders.

Reservoirs

Circular Concrete Reservoirs at Leamington, Ont., Edward M. Proctor. Can. Engr., vol. 36, no. 19, May 8, 1919, pp. 433-435, 8 figs. Provide storage of 1,000,000 imp. gal. Low unit stress has been used for steel and walls are entirely separate from floor.

Oil Fuel Reservoir of Rosyth. Engineer, vol. 127, no. 3301, Apr. 4, 1919, pp. 324-325, 2 figs. Concrete structure on rock foundation; walls built in form of retaining walls with average height of 35 ft., and reinforced with steel rods laid in direction of length of wall in layers 3 ft. apart in vertical direction, and spaced from 1 ft. to 4 ft. apart in horizontal direction.

Roofs

Erecting Long-Span Roof over Steel Mill by Rolling Trusses to Place. Eng. News-Rec., vol. 82, no. 19, May 8, 1919, pp. 898-902, 8 figs. Trusses rolled along craneway in groups weighing 800 tons.

School House

Standard School House Equipment and Details. Am. Architect, vol. 115, no. 2263, May 7, 1919, pp. 657-663, 11 figs. N. Y. City practice of forming folding partitions.

Vibrations

Vibrations in Buildings Due to Electrical Machinery, A. B. Eason. Post Office Elec. Engrs. Jl., vol. 12, part 1, Apr. 1919, pp. 32-40, 3 figs. Noise and vibration dealt with is that being due to telephone charging sets and ringing machines. Various reports dealing with conditions in post-office telephone exchanges are mentioned.

Warehouse

Eaton Mail Order Building, Moncton, N. B. Contract Rec., vol. 33, no. 20, May 14, 1919, pp. 449-450, 2 figs. Six-story flat-slab reinforced-concrete warehouse.

CEMENT AND CONCRETE

Car Floats

Construction of Concrete Car Floats for the Government. Concrete, vol. 14, no. 5, May 1919, pp. 181-183, 8 figs. Concrete is poured in three units: (1) bottom skin, keelsons and frames, and outside skin and frames; (2) bulkheads; (3) stanchions, deck beams, girders and deck slabs.

Concrete Mixes

Correct Proportioning of Concrete Mixes, Duff A. Abrams. Am. Architect, vol. 115, no. 2265, May 21, 1919, pp. 721-733, 9 figs. Report of investigations covering consistency (quantity of mixing water), size and grading of aggregates, and mix (proportion of cement) conducted during past three years at Structural Materials Research Laboratory, Lewis Institute, Chicago, with coöperation of Am. Inst. of Architects and Portland Cement Assn.

Design of Concrete Mixtures, Duff A. Abrams. Concrete, vol. 14, no. 5, May 1919, pp. 191-195, 4 figs. Results of investigations conducted at Lewis Institute, Chicago, covering relation between consistency, size and grading of aggregates and mix.

Iron Portland Cement

Iron Portland Cement in Reinforced Concrete, Edwin H. Lewis. Iron & Coal Trades Rev., vol. 98, no. 2669, Apr. 25, 1919, p. 510. Claims that in properly made iron portland cement there should be no difficulty in keeping sulphur percentage below requirements of British standard specification. Paper before West of Scotland Iron & Steel Inst.

Mortars and Concretes, Physical Properties of

Physical Properties of Mortars and Concretes, H. M. Thompson. Can. Eng., vol. 36, no. 18, May 1, 1919, pp. 415-422 and 429, 18 figs. Tests show that 1:2 mortar without addition of chemicals and cured in a moist closet resists attack by alkali solution, but is disintegrated when steam-cured; addition of soap and aluminum sulphate decreases strength of mortars and renders them more liable to disintegration.

Pneumatic Concreting

Pneumatic Method of Concreting, H. B. Kirkland. Cement & Eng. News, vol. 31, no. 5, May 1919, pp. 23-25, 3 figs. Consist in blowing batches of concrete through pipe from central point of supply to their place into concrete form.

Retaining Wall

New Type of Sectional Concrete Retaining Wall. Ry. Rev., vol. 64, no. 19, May 10, 1919, pp. 690-691, 4 figs. Material in form of 8-in. reinforced-concrete I-beams was secured and laid in form of cribbing or retaining wall.

Rodding

Improving Concrete by Rodding, F. E. Giesecke. Eng. News-Rec., vol. 82, no. 20, May 15, 1919, pp. 957-958, 2 figs. Tests are said to have shown that strength is increased materially by continuous agitation of wet concrete with rods.

Setting Time of Portland Cement

Notes on the Setting Time of Portland Cement, F. Esling. Jl. Soc. Chem. Indus., vol. 38, no. 7, Apr. 15, 1919, pp. 81T-82T. Advocates further revision of standard specification of cement testing in respect to water that should be used in gaging cement-setting-time tests, and for this purpose distilled water is suggested as most readily obtainable standard.

Slag Production

Largest Slag Producer in America. Cement Mill & Quarry, vol. 14, no. 9, May 5, 1919, pp. 11-13, 14 figs. Plant at Ensley designed to produce 4000 tons of basic slag, crushed and screened in seven standard sizes.

Trunking, Concrete

Construction and Use of Concrete Trunking, B. A. Lundy. Ry. Signal Engr., vol. 12, no. 5, May 1919, pp. 169-170, 2 figs. Scarcity of cypress and high cost of sizes required led to development of this type.

See also RAILROAD ENGINEERING, Permanent Way and Buildings (Abutments and Grade Crossings.)

EARTHWORK, ROCK EXCAVATION, ETC.

Dams

Sweetwater Dam Enlarged for the Third Time, H. N. Savage. Eng. News-Rec., vol. 82, no. 20, May 15, 1919, pp. 948-952, 6 figs. Construction of siphon spillways and enlargement of weir spillways to take care of maximum flood.

Dredging

Embankments of the Zuider Zee (De dijken in de Zuiderzee), K. dem Tex. De Ingenieur, vol. 34, no. 13, Mar. 29, 1919, pp. 227-228. Advantage claimed for suction dredges with pressure pipes is great output independent of wind and weather.

Filling

Computation of Time Required to Fill a Graving Dock, Eugene E. Halmos. Eng. News-Rec., vol. 82, no. 19, May 8, 1919, pp. 920-921, 1 fig. Based on method of filling from upper orifice or from usual gate openings at bottom of dock.

Inspection of Dredging

Inspection of Drainage Ditch Cross-Sections After Contract Dredging, E. S. Blaine. Eng. News-Rec., vol. 82, no. 21, May 22, 1919, pp. 1019-1022, 7 figs. Soundings made by level rod gave way to lead and line following along tape.

Sinking

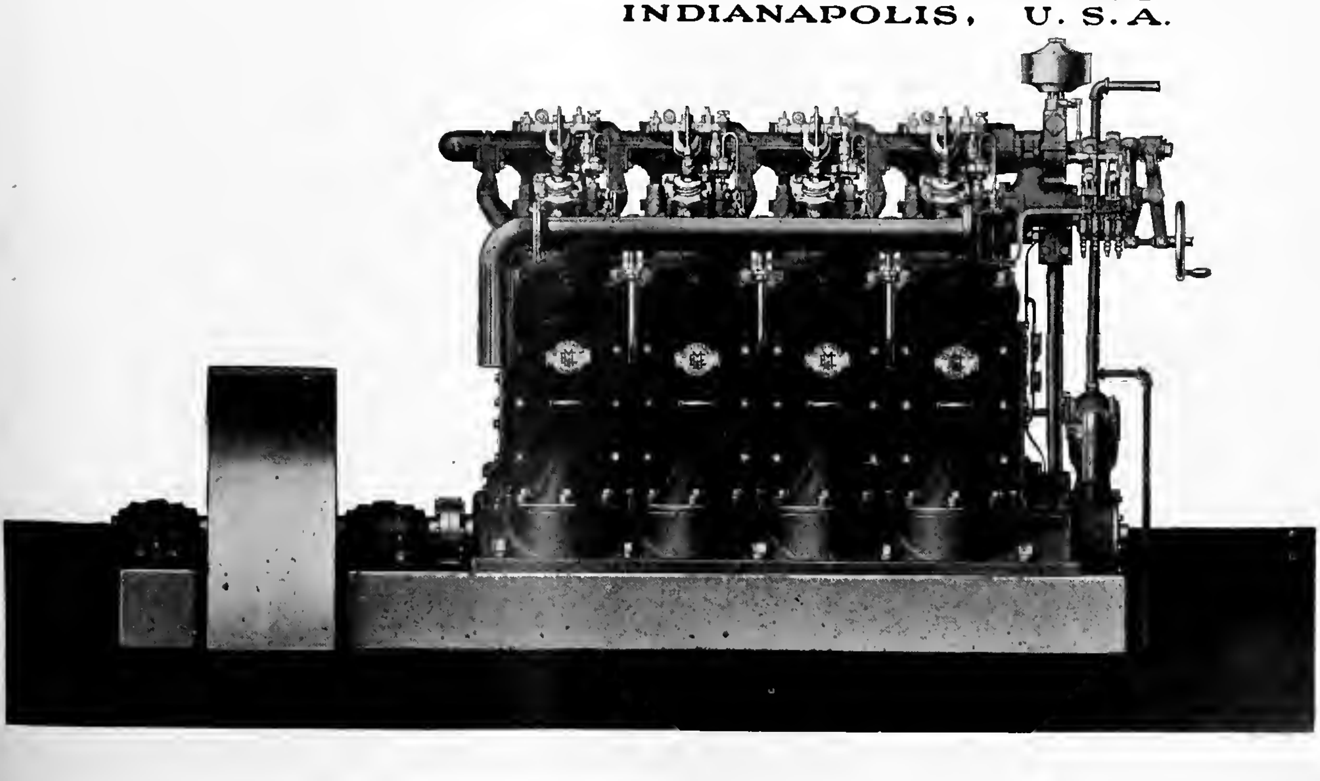
Sinking a Concrete Pumping Station in a River, Keith O. Guthrie. Eng. News-Rec., vol. 82, no. 21, May 22, 1919, pp. 1013-1016, 6 figs. House consisting of concrete cylinder 30 ft. in diameter lowered while being built from frame controlled by ratchet wrenches tied together for simultaneous movement.

Steam Shovel

A Review of Modern Steam Shovel Practice, with Recommended Procedure, Llewellyn N. Edwards. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 176-179, 3 figs. Economy and efficiency of shovel operation believed to be mainly dependent on properly proportioned combination of latent power of machine with skill and experience of operator.

Tunneling

Tunnel Between Denmark and Sweden (Om tunnelbanen København-Malm), Heinrich Obrt. Ingenioren, vol. 28, no. 15, Feb. 19, 1919, pp. 94-95. Project contemplates connection across harbor dam with Amagar Island. It is proposed to sink shafts at Saltohlm Island from which tunneling will be carried in two directions. Total length to be 31¼ miles of which 11 miles will be below sea level.



HARBORS

Philadelphia

Harbor Developments of the Port of Philadelphia in Progress and Contemplated, W. B. Ladue. Jl. Engrs. Club Philadelphia, vol. 36-5, no. 174, May 1919, pp. 188-193. Forecasts great future for this port, and suggests advertising its present possibilities.

MATERIALS OF CONSTRUCTION

Liquid Air for Blasting

Liquid Air as an Explosive (Het schieten met vloeibare lucht in de Nederlandsche Kolenmijnen), W. H. D. de Iongh. De Ingenieur, vol. 34, no. 10, Mar. 8, 1919, pp. 176-179, 2 figs. Experiments with cartridges containing finely powdered soot, charcoal, bituminous coal, paper, cork, reed and sawdust saturated with liquid air. This explosive is said to have been found equal to dynamite.

Roofing Materials

Bituminous Roofing Materials and Construction—II, George Landis Wilson. Chem. & Metallurgical Eng., vol. 20, no. 9, May 1, 1919, pp. 484-486, 4 figs. Comparative tests of thickness, tensile strength, absorption of moisture, pliability, volatility and fillers.

ROADS AND PAVEMENTS

Asphalt

Hot Mix Asphalt Pavements, Francis P. Smith. Can. Engr., vol. 36, no. 21, May 22, 1919, pp. 472-474 & 482. Determining character of drainage and on manner of utilizing existing pavements. Paper read before Sixth Can. Good Roads Congress.

Bituminous Pavements

Defects in Surface of Bituminous Pavement Due to Concrete Base, H. W. Skidmore. Eng. News-Rec., vol. 82, no. 18, May 1, 1919, pp 878-880. Data collected at Oak Park, Ill., interpreted as indicating that cracks and other objectionable features are a minimum where flexible foundations are used.

Efficiency of Bituminous Surfaces and Pavements Under Motor Truck Traffic, Prevost Hubbard. Am. City, City Edition, vol. 20, no. 5, May 1919, pp. 455-458.

Brick

Design and Construction of the Monolithic Brick Road South of Seneca, Ill., A. H. Hunter. Mun. & County Engr., vol. 56, no. 5, May 1919, pp. 161-163, 6 figs. Plans called for alteration of grade by reduction to maximum of 7 per cent, a specification which required heavy excavation on hill.

Brick Pavements in the Middle West, A. T. Goldbeck and F. H. Jackson. Public Roads, U. S. Dept. Agriculture, Bur. Public Roads, vol. 1, no. 10, Feb. 1919, pp. 3-18, 14 figs. Writers conclude from their survey that type and thickness of base should depend upon maximum load or weight to be carried and the bearing value, under all weather conditions, of the underlying soil. Further conclusions applying to special cases were also formed.

General Features of Brick Pavement Construction, A. T. Goldbeck and F. H. Jackson. Eng & Contracting, vol. 51, no. 19, May 7, 1919, pp. 479-481. From observations made during inspection trip of large number of brick roads in the Middle West. See note to preceding item.

Present Status of Brick Pavements Constructed with Sand Cushions, Cement Mortar Beds, and Green Concrete Foundation, Wm. M. Acheson. Better Roads & Streets, vol. 9, no. 3, Mar. 1919, pp 83-84. Paper before Am. Road Builders' Assn.

Concrete Highway Standards

Concrete Highway Construction Standards Raised. Eng. News-Rec., vol. 82, no. 20, May 15, 1919, pp. 955-956. Mississippi Valley State Road Officials recommend tamped concrete and heavier sections.

Concrete Sidewalks

Design of Concrete Sidewalks and Concrete Curb and Gutter at Street Intersections, W. Robert Paige. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 188-189, 3 figs. Examples of lines of walks and curves, intersected at angle of 78 deg. 14 min. on one side and 101 deg. 46 min. on other side.

Cost Charts

The Cost of a Mile of Road, George A. Duren. Eng & Contracting, vol. 51, no. 19, May 7, 1919, pp. 485-486, 3 figs. Charts based on prices assumed as averages. Paper presented before Engrs. & Road Builders' Congress.

Dixie Highway

Design and Construction of the Dixie Highway from Rockwood to Monroe, Mich. Leroy C. Smith. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 163-165, 2 figs. Metal top is 18 ft. wide with uniform thickness of 7 in. and 5-ft. shoulders. Grade is uniform, with no heavy cuts or fills, country being low and level and soil a heavy clay the entire length.

Easements and Superelevations

Superelevations and Easements, George Alden Curtis. Good Roads, vol. 17, no. 19, May 10, 1919, pp. 199-201, 5 figs. Field methods of constructing pavements with banked and easement curves.

Guarantees

Pavement Guarantees. Mun. Jl. & Public Works, vol. 46, no. 20, May 17, 1919, pp. 355-356. Practice of counties throughout U. S. A. as to requiring them and opinions of county officials as to their desirability.

Finishing Concrete Roads

The Finishing of Concrete Roads by Machine, E. G. Carr. Am. City, Town & County Edition, vol. 20, no. 5, May 1919, pp. 429-431, 2 figs. Illustrating how entrapped air is removed from concrete by alternating pressure.

Illinois

Illinois Adopts a Uniform Basis of Design for all Types of Rigid Pavement, Clifford Older. Eng. News-Rec., vol. 82, no. 19, May 8, 1919, pp. 905-907. State bond issue of \$60,000,000 together with about \$24,000,000 of Federal aid appropriation is to be expended for road building. It has been decided to use mainly concrete but brick or bituminous-concrete on concrete base have also been considered for main roads.

Macadam

Bituminous Macadam, A. W. Dean. Can. Engr., vol. 36, no. 21, May 22, 1919, pp. 469-470. Various rules are given for preventing unsatisfactory results with bituminous macadam.

Marker, Standardization

Uniform Markers for Our Highways, Roy E. Berg. Motor Age, vol. 35, no. 20, May 15, 1919, pp. 30-32, 14 figs. Road signs recommended for standardization.

Pavings for Electric-Railway Tracks

Investigation of Pavings for Electric Railway Tracks, H. S. Cooper. Elec. Traction, vol. 15, no. 5, May 1919, pp. 318-328. Advises that in comparing various types and kinds of paving it is well to consider that each has the type of base or foundation best suited to its stability as a whole and that such base or foundation is of ample strength of itself to relieve paving of any stresses or strains other than those which crush, roll or otherwise disintegrate or wear the actual body of the paving itself.

Road Oil

The Use of Road Oil. Am. City, Town & County Edition, vol. 20, no. 5, May 1919, pp. 423-427, 2 figs. Costs and tentative specifications prepared for highway engineers.

State Highway Management

State Highway Management, Control and Procedure, M. O. Eldridge, G. G. Clark and A. L. Luedke. Public Roads, U. S. Dept. Agriculture. Bur. Public Roads, vol. 1, no. 10, Feb. 1919, pp. 29-103, 28 figs. Schematic diagram of organization in state highway forces in 28 states.

Washington (State)

The Road Building Sands and Gravels of Washington, Morris M. Leighton. Wash. Geol. Survey, bul. 22, 1919, 307 pp., 45 figs. Studies covered (1) field examination to determinate nature, extent and manner of occurrence, and (2) laboratory tests to ascertain probably quality for gravel macadam and the various forms of pavement in which sand and gravel are used.

Wood-Block Pavement

Procedure in Constructing an Open Joint Wood Block Pavement at Toledo, Ohio, Raymond Pierce. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 174-175, 2 figs. Work carried on during winter months. Tractor was used to steam stone and sand and to furnish hot water for concrete mixer.

SANITARY ENGINEERING

Comfort Stations

Comfort Stations Are National Necessities. Domestic Eng., vol. 87, no. 5, May 3, 1919, pp. 186-188 and 223, 2 figs. Need of immediate erection of public conveniences believed to be important part of reconstruction program. Arrangement suggested.

Sewage Disposal

Results of Experiments With Miles Acid Process of Sewage Treatment, Edgar S. Dorr. Eng. & Contracting, vol. 51, no. 20, May 14, 1919, pp. 510-513. From experiments conducted at various institutions it is concluded that Miles process will produce a well-disinfected effluent from which 90 per cent. of settleable solids and 99 per cent. of the bacteria have been removed. From Jl. Boston Soc. Civil Engrs.

The Sewage Disposal Problem in Chicago, C. D. Hill. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 180-181. Dilution process used.

Sewage Screens

Operation of Fine Sewage Screens at Long Beach, California. Eng. News-Rec., vol. 82, no. 21, May 22, 1919, pp. 1012-1013. Tests reported to have indicated that screens remove 16.3 per cent. of solids.

Sludge Activation

Activated Sludge Experiments at Sheffield—Successful Results by Agitation, John Haworth. Contract Rec., vol. 33, no. 19, May 7, 1919, pp. 438-439, 1 fig. Analysis of samples from experimental aeration plant, Sheffield Sewage Works.

SURVEYING

Astronomical Meridian Determination

Polaris Observations for Azimuth in Northern Latitudes, J. Maughs Brown. Eng. Education, Bul. Soc. for Promotion of Eng. Education, vol. 9, no. 8, Apr. 1919, pp. 305-316, 4 figs. Suggestions intended to simplify field work and computations in determining astronomical meridian.

Magnetic Meridian Determination

A Method of Determining the Magnetic Meridian as a Basis for Mining Surveys, T. Lindsay Galloway. Trans. Instn. Min. Engrs., vol. 56, part 4, Apr. 1919, pp. 222-227 and (discussion) pp. 227-235, 3 figs. Describes theodolite and three tripods, and appliance termed "magnetic reflector," which consists of a small plate-glass mirror to which is cemented a flat magnetized bar, the whole being delicately suspended by a single fiber of unspun silk. These apparatus are introduced in writer's method for the purpose of correcting what he terms the deficiencies in Beanland's extension of astronomical methods to underground surveying.

Spirit Leveling

Spirit Leveling, R. B. Marshall. Dept. of the Interior, U. S. Geol. Survey, bulletins 632 to 636 and 638. In W. Va., Me., La., Ga., Ark.; and N. Mex. A separate bulletin for each state.

WATER SUPPLY

Factory Water Supply

What It Pays to Know About Factory Water Supply—III, Charles L. Hubbard. Factory, vol. 22, no. 5, May 1919, pp. 919-923, 7 figs. Contaminated drinking water supplied to workers said to have cost one company \$50,000 in death and sickness claims.

Filtering at High Rate

Reports on Detroit Waterworks. Mun. Jl. & Public Works, vol. 46, no. 19, May 10, 1919, pp. 334-337. Investigation conducted under auspices of Board of Water Commissioners concerning possibilities of filtering water at high rate.

Reservoirs

The High Service Reservoir of the St. Paul, Minn., Water Works, W. N. Jones. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 165-168, 6 figs. Investigation of proposition relative to securing entire city supply from artesian well and using Mississippi river as source of supply.

Improving Providence Water Supply, John Rositer Hess, Jr. Mun. Jl. & Public Works, vol. 46, no. 20, May 17, 1919, pp. 350-353. Temporary dam and regulating dam with spillway of horseshoe shape. Reservoir is expected to permit elimination of pumping.

Testing Stations, Water Purification

Testing Stations for Determining Critical Factors for Water Purification Plant Design, W. T. McClenahan and R. S. Rankin. Eng. & Contracting, vol. 51, no. 20, May 14, 1919, pp. 515-516. Purpose of station was to study (1) effect of aeration on odor and taste, (2) kind and amount of chemical to be used and its effect on odor and taste, (3) period of sedimentation and time of contact giving best results, and (4) peculiarities in treatment of water contaminated by oil.

VIEWS illustrating the quantity production of "Chicago Pneumatic" Compressors. The Franklin, Pa., plants, here partially illustrated, cover more than eight acres of ground.

The Production Efficiency Back of "Chicago Pneumatic" Air Compressors

—like their well-known operating efficiency, is an asset to users in this definite way:

Every "Chicago Pneumatic" Compressor built is comprised of parts made to an accurate system of jigs, fixtures and templates which, supplemented by careful inspection and tests, maintains a dimensional uniformity of parts so accurate that replacements for any of *300 distinct sizes and types of compressors* may be ordered with the assurance that they will be strictly interchangeable with the old. The uniform quality and performance of each machine is a standardized certainty.

The production in large quantities of air compressor equipment, justifies an elaborate manufacturing system of this kind. Its development by the builders of "Chicago Pneumatic" Compressors is another indication of the broad service and engineering policies of this Company; another reason, why "Chicago Pneumatic" Compressors being *built* for better service, *give* it!

Regardless of your requirements there is a "Chicago Pneumatic" Air Compressor available to best fulfill them.

"CHICAGO PNEUMATIC"

The Compressor with the Simplate Valve

Water Softening

Water Softening for Municipalities, Milton F. Stein. Jl. Am. Water Works Assn., vol. 6, no. 2, June 1919, pp. 202-214, 5 figs. Essential features of softening plants are held to be mixing chambers in which softening reagents are thoroughly dispersed through the raw water, either by mechanical devices or by baffling, large settling basins whose capacity is based upon reaction period as determined for conditions of minimum temperature and means for adding a coagulant solution either at entrance to or near exit from settling basins or at both points.

WATERWAYS

Canal, Adriatic to Switzerland

From the Adriatic to Switzerland by Canal Boat (Dall' adriatico alla Svizzera per canali navigabili), Guido Po. Rivista Marittima, vol. 52, no. 3, Mar. 1919, pp. 289-308, 11 figs. Venice-Brondola-Pizzighettones, up rivers Po and Adda and industrial canal to Milan. In process of construction.

Flood-Water Control

The Control of Flood Water in Southern California, Edw. N. Munns. Jl. Forestry, Soc. Am. Foresters, vol. 17, no. 4, Apr. 1919, pp. 423-429, 1 fig. Construction of stone check-dams so placed across channel that the water, although able to percolate through them to some extent, collects in a basin behind the dam and then falls vertically, or nearly so, over its front face.

Short-Circuiting Floods in the Big Sioux River, Francis C. Shenehon. Eng. News-Rec., vol. 82, no. 20, May 15, 1919, pp. 961-964, 5 figs. Plan of spillway to guard against flood water in Big Sioux River near Sioux Falls, S. D.

VARIA

Stump Removal

Methods and Costs of Stump Removal in Land Clearing, F. M. White and E. R. Jones. Eng. & Contracting, vol. 51, no. 21, May 21, 1919, pp. 535-537, 3 figs. Examples of dynamite charges in various cases and stumping records made by crews. Investigations by Agricultural Experiment Station, Univ. of Wisconsin. Pulling with horse puller and then cracking with dynamite said to have been found to be the most economical method of stump removal.

Mining Engineering

BASE MATERIALS

Clays

Ball Clays of West Tennessee, Rolf A. Schroeder. Resources of Tennessee, State Geol. Survey, vol. 9, no. 2, Apr. 1919, pp. 81-180, 13 figs. Investigation covered location, geological relations and economic importance. Laboratory tests were made at Ceramic Laboratory, University of Illinois.

Garnet

Garnet in North Carolina and the Market for Abrasive Garnet, Frank J. Katz. Eng. & Min. Jl., vol. 107, no. 21, May 24, 1919, pp. 903-906. Report of examination of deposits and of canvass of producers and consumers.

COAL AND COKE

Alaska

The Nenana Coal Field, Alaska, G. C. Martin. Dept. of the Interior, U. S. Geol. Survey, bul. 664, 1919, 54 pp., 12 figs. Geology, geography and general features. Coal is classified as lignite of good grade.

Belgium

The Coal Beds of Belgium (Les gisements houillers de la Belgique), Armand Renier. Annales des Mines de Belgique, vol. 20, first issue, 1919, pp. 227-258. Stratigraphy. (Continuation of serial.)

Canada

Coal Resources of Western Canada—II, James White. Coal Age, vol. 15, no. 19, May 8, 1919, pp. 858-862, 1 fig. Government is reported to favor plan to carbonize low-grade coals of Saskatchewan for the purpose of saving freight and by-products.

Carbonization

Some Features of Carbonisation and By-Product Recovery, J. Thorp. Colliery Guardian, vol. 117, no. 3044, May 2, 1919, pp. 1015-1016, Beehive vs. patent coke for steel smelting. Paper read before Coke Oven Managers' Assn. (Midland Section).

Carbonizing Process, Low Temperature

G-L Low-Temperature Carbonizing Process. Coal Age, vol. 15, no. 18, May 1, 1919, pp. 810-812, 5 figs. Gases, oil and tars are liberated from coal at maximum temperature within retort not exceeding 1200 deg. fahr.; oils are thus expelled as vapors without being broken down by heat into gases; after removal from retorts they are condensed into liquid oils.

Coal-Cutting Machinery

Comparative Working Costs of Electrical and Compressed-Air Coal-Cutting Machines (Longwall) with Increased Outputs over Hand Hewing, F. A. Hale. Iron & Coal Trades Rev., vol. 98, no. 2668, Apr. 18, 1919, p. 478. Series of tests is presented in substantiation of writer's objections to installation of longwall coal-cutting machines in collieries. Paper read before North of England Branch Assn. Min. Elec. Engrs.

Coal Gas

Coal: Its Value as a Raw Material for Distillation Products—IV, Coal Gas, J. A. Wilkinson. South African Jl. Industries, vol. 2, no. 3, Mar. 1919, pp. 239-246, 1 fig. Methods of producing coal gas. (Concluded.)

Coke Ovens

New Coke Ovens at the Providence Gas Works, Edward D. Bauer. Gas Age, vol. 43, nos. 9 & 10, May 1 & 15, 1919, pp. 461-465 & 516-520, 17 figs. Plant has nominal capacity of 7,500,000 cu. ft. of gas per day and consists of one battery of 40 by-product coke ovens equipped coal-handling conveyors, crushing and mixing apparatus and bins for preparing coal, 750-ton coal-storage bin, quenching station, coke-handling conveyors and both metallurgical and domestic coke-screening stations. Three reversing machines—one damper and air-valve reversing machine and two gas-coke machines (one for coke side and one for crusher side gas coke).

Modern Coke Oven and By-Product Plant, Drummond Paton. Iron & Coal Trades Rev., vol. 98, no. 2668, Apr. 18, 1919, pp. 470-471. In discussing schemes suitable for Lancashire coal, writer remarks on features of low temperature, high temperature or gasification as factors determining successful operation. Paper read before Manchester Geol. & Min Soc.

Coking Low-Grade Fuel

Utilization of Mine Waste and Low-Grade Fuels (Utilisation des déchets de mines et des mauvais combustibles), F. Blache. Bulletin et comptes rendus mensuels de la Société de l'Industrie Minérale, series 5, vol. 15, first issue of 1919, pp. 5-28, 2 figs. Scheme for coking fuel with recuperation of by-products and purifying coke.

Coking Output of Coals

Coking Output of Coals (Quelques notes sur le pouvoir cokéfiant des charbons). Annales des mines de Belgique, vol. 19, third issue, 1914, pp. 625-651. Experiments with English, Belgian and German samples to determine agglutinant power as index of quality.

Costs

Coal-Mining Costs and Output. Times Eng. Supp., vol. 15, no. 554, Apr. 1919, p. 129. Comparison with America.

Kent, England

The Evolution and Development of the Kent Coalfield, A. E. Ritchie. Iron & Coal Trades Rev., vol. 98, nos. 2662, 2668, 2669, and 2670, Mar. 7, Apr. 18 & 25, May 2, 1919, pp. 289-290, 476-477, 508-509, and 537-538, 6 figs. From 1901 to 1905; operations in the latter part of 1906 and during 1907; from 1909-1910; comparative sections of pits at Dover and Tilmanstone to show strata between Gault and coal measures are illustrated; from 1911 to 1912; diagramatic section showing general position of Tilmanstone pits. (Continuaton of serial.)

Methane Accumulations

Methane Accumulations from Interrupted Ventilation, H. I. Smith and R. J. Hamon. Colliery Guardian, vol. 117, no. 3042, Apr. 17, 1919, pp. 895-896, 2 figs. Tests conducted in three mines—two in Southern Illinois and one in Indiana—showed that methane may accumulate from (1) sudden liberation from seams, cracks or other feeders, (2) emission from inaccessible and abandoned workings, as a result of either an increase or decrease in pressure of ventilating current and, (3) local accumulations resulting from any interruption of normal ventilating current.

Pyrites

Pyrite Deposits in Ohio Coal, W. M. Tucker. Economic Geolog., vol. 14, no. 3, May 1919, pp. 198-219, 3 figs. Total possible production of pyrite estimated at 250,000 tons yearly.

Recovery of Pyrite from Washery Refuse, E. A. Holbrook. Coal Age, vol. 15, no. 19, May 8, 1919, pp. 848-851, 4 figs. Efficiency of recovery of about 70 per cent is said to be realized by installation and operation of crushing, screening, jigging and sometimes tabling apparatus.

Screening Plant

Thurcroft Main Colliery. Iron & Coal Trades Rev., vol. 98, no. 2662, Mar. 7, 1919, pp. 279-280, 2 figs. & supp. plates. Equipment for an output of 4000 tons daily. Screening plant comprises several units each capable of dealing with 120 tons per hour.

Stripping

Coal Stripping in the United States—V, Wilbur Greeley Burroughs. Coal Indus., vol. 2, no. 5, May 1919, pp. 177-182, 2 figs. Differences between systems followed in bituminous and anthracite fields.

Russia

At the Anthracite Mines, South Russia, in the Early Days of the War, A. L. Simon. Min. Mag., vol. 20, no. 4, Apr. 1919, pp. 203-211, 2 figs. Area over which mining rights extend approximates 10,000 acres. Mine water, boiler house, winding engines and labor conditions are discussed from viewpoint of adaptability to special requirements and susceptibility to improvements.

Tipple and Washeries

New Tipple of the Granby Consolidated Mining, Smelting & Power Co., F. E. Mueller. Coal Age, vol. 15, no. 18, May 1, 1919, pp. 804-805, 3 figs. General layout of tracks, tipple and proposed washery, and details of solid-body mine car.

See also RAILROAD ENGINEERING, (Locomotives) (Pulverized Coal.)

COPPER

Leaching Ores

Leaching of Oxidized Copper Ores with Ferric Chloride, R. W. Perry. Min. & Sci. Press, vol. 118, no. 20, May 17, 1919, pp. 669-674, 2 figs. Patented process based on: $3 Cu O + 2 Fe Cl_3 + 3 H_2 O = 3 Cu Cl_2 + 2 Fe (OH)_3$; $3 Cu Cl_2 + 3 Fe = 3 Cu + 3 Fe Cl_2$; and $3 Fe Cl_2$ + Electricity = $Fe + 2 Fe Cl_3$.

See also MECHANICAL ENGINEERING, Materials of Construction and Testing of Materials (Copper.)

GEOLOGY AND MINERALOGY

Australia

A Geological Reconnaissance of the Country Between Laverton and the South Australian Border (near South Latitude 26 deg.), Including part of the Mount Margaret Goldfield, H. W. B. Talbot and E. de C. Clarke. Geol. Survey, Western Australia, bul. no. 75, 1917, 207 pp., 72 figs.

Brazil

Notes on the Geology of the Diamond Region of Bahia, Brazil, Roderic Crandall. Economic Geology, vol. 14, no. 3, May 1919, pp. 220-244, 14 figs. Opinions expressed by various explorers.

Chisone Valley

Contribution to the Study of Minerals in the Chisone Valley (Contributo allo studio dei minerali della Valle del Chisone), E. Grill. Atti della Societé Toscana di Scienze Naturali, Memorie, vol. 31, 1917, pp. 140-167, 6 figs. Pyrite, albite magnetite, dolomite, apatite, tremolite, actimolite, tourmaline and ilmenite.

Crystallography

Crystallography of some Canadian Minerals: 9. Cerussite, Eugene Poitevin. Am. Mineralogist, vol. 4, no. 5, May 1919, pp. 56-58, 3 figs. Crystals show three habits: Tabular crystals with large brachypinacoid, pyramidal crystals with well-developed prisms and pyramids and limited domes, and pyramidal crystals having r (130) as twinning plane.

Artificial Coloration of Helicoid Spherolites as Means to Determine Polymorphous Modifications (Coloration artificielle des sphérolites à enroulement hélicoïdal et distinction des modifications polymorphes par la couleur acquise), P. Gaubert. Bulletin de la Société Française de Minéralogie, vol. 41, nos. 7-8, July-Dec. 1918, pp. 198-224, 6 figs. Account of experiments. Coloring matter and colorless substance group themselves so as to form mixed crystals. Asparagine, tartrates and bimalates considered.

Georgia

Report on the State Deposits of Georgia. H. K. Shearer. Geol. Survey of Ga., bul. 34, 1918, 192 pp., 24 figs. Geological formations of Appalachian Valley and Cumberland Plateau areas. Only along eastern border, near Cartersville, are shaly beds considered as commercially valuable slates.

New Minerals

Review of New Mineral Species (Revue des espèces minérales nouvelles). P. Gaubert. Bulletin de la Société Française de Minéralogie, vol. 41, nos. 7-8, July-Dec. 1918, pp. 224-226. Coleraininte, collbranite and gilpinite.

Oregon

The Salient Features of the Geology of Oregon. Warren Dupre Smith and Earl L. Packard. Jl. of Geology, vol. 27, no. 2, Feb.-Mar. 1919, pp. 79-120, 3 figs. Including bibliography of important articles.

Tasmania

The North Pieman and Huskisson and Sherling Valley Mining Fields. A. McIntosh Reid. Tasmania Dept. Mines, Geol. Survey bul. 28, no. B-82381, 1918, 132 pp., 13 figs. Geological data, location and area, and topographical details.

Tonopah Divide

The Divide District. Frank L. Sozer. Min. & Sci. Press, vol. 118, no. 19, May 10, 1919, pp. 631-633, 4 figs. Important geological features of the Tonopah Divide are the pronounced fissuring and the volcanic uplift.

Water in Rock Formations

Water Expectancy in Tunnels, Mines and Deep Wells in Homogeneous Rocks. Robert E. Horton. Jl. Am. Water Works Assn., vol. 6, no. 2, June, 1919, pp. 183-186. Proposes method and formulæ by which data obtained from surface wells can be applied. Method is limited to cases where bedrock is somewhat uniform in character throughout all depths from rock floor down to bottom of tunnel or other structure.

LEAD, ZINC, TIN

Lead from Vanadinite

A Proposed Metallurgical Process for the Treatment of Vanadinite for the Recovery of Lead and Vanadium. J. E. Conley. Chem. & Metallurgical Eng., vol. 20, no. 10, May 15, 1919, pp. 514-518, 2 figs. Vanadinite concentrate is fluxed and reduced with soda ash, caustic and carbon, giving metallic lead; slag is elutriated Si and Mo precipitated with lime; vanadium pentoxide precipitated by boiling in acid solution.

Sintering Zinc Residues

Sintering Zinc Residues. K. Stock. Chem. & Metallurgical Eng., vol. 20, no. 10, May 15, 1919, pp. 525-537, 16 figs. Methods used by Bartlesville Zinc Co. After roasting and retorting, all residues are subjected to additional treatment depending upon amount and nature of metals to be recovered.

MAJOR INDUSTRIAL MATERIALS

Nickel

Canada Controls Nickel Output of the World. W. P. Sutherland. Can. Machy., vol. 20, no. 26, Dec. 26, 1918, pp. 730-736, 13 figs. Plant of International Nickel Co. of Canada at Port Colborne. Reference is made to laboratory and refineries.

See also METALLURGY, Aluminum, Copper and Nickel, and Iron and Steel.

MINES AND MINING

Bore-Hole, Diamond

Some Difficulties met with in Putting Down Diamond Bore-Hole Underground. J. Walker Steele. Iron & Coal Trades Rev., vol. 98, no. 2662, Mar. 7, 1919, p. 292, 1 fig. Account of difficulties met and dealt with in putting down 2-in. diamond borehole for the proving of underlying seams in faulty and difficult ground.

Cartridges, Safety

Safety Cartridge (Etude d'une Cartouche de Sûreté). Emmanuel Lemaire. Annales des Mines de Belgique, vol. 19, third issue, 1914, pp. 587-590. Mixture of calcium fluoride, sodium chloride, iron sulphate and sand reported found from experimental research to insure safety and permit minimum cartridge diameter. First article.

Concentrate Treatment

New Process for the Mechanical Preparation of Minerals (Nouveaux procédés de préparation mécanique des minerals). Echo des Mines et de la Metallurgie, vol. 47, no. 2620, Apr. 6, 1919, pp. 217-218. Wolfram and cassiterite mixed concentrates treated in Rapid apparatus.

Concentration

Economies of Concentration. A. P. Watt. Eng. & Min. Jl., vol. 107, no. 18, May 3, 1919, pp. 775-776, 3 figs. Evidence offered in substantiation of suggested advisability for operating a separate heat-treatment plant.

Deep Mines, Cooling and Drying

Cooling and Drying in Deep Mines. Sidney F. Walker. Refrig. World, vol. 54, no. 5, May 1919, pp. 23-24. Recommends refrigeration and cold-storage methods to make coal more accessible.

Explosives, Storage

Storage of Powder and Explosives at Coal Mines. E. M. Kimball. Coal Age, vol. 15, no. 18, May 1, 1919, pp. 794-795, 1 fig. Example of magazine built on brick foundation.

Geophone

The Geophone. Eng. & Min. Jl., vol. 107, no. 20, May 17, 1919, pp. 872-873, 2 figs. Invented by French to detect enemy sapping and underground mining operations and for ascertaining position of enemy artillery.

Hoisting

Hoisting in Coal Mines. W. J. Heeley. Can. Min. Inst. bul. no. 85, May 1919, pp. 498-503, 1 fig. Lines which writer believes to be close approximation to economy, from viewpoint of rope, for relative positions of drum and pulley, for shafts from 100 to 600 yards winding depth.

Lamp, Safety

The Chance Acetylene Safety-Lamp. William Maurice. Trans. Instn. Min. Engrs., vol. 56, part 4, Apr. 1919, pp. 273-280 and (discussion) pp. 280-284, 9 figs. Combines American type of Wolf lamp with Mueseler principle. It is provided with roof reflector which distributes illumination sidewise, thus making it unnecessary to tilt lamp.

Safety Lamp Gauzes—V. T. J. Thomas. Colliery Guardian, vol. 117, no. 3042, Apr. 17, 1919, pp. 898-899. Compilation of data on uses of non-ferrous metals as recorded by various experimenters.

Loading Machinery, Underground

Underground Coal-Loading Machinery. E. N. Zern. Coal Age, vol. 15, no. 18, May 1, 1919, pp. 784-791, 10 figs. Remarks in reference to results obtained in some mines that it is manifestly unfair to put any coal-loading machinery to work unless mining, haulage and other conditions are made favorable to its operation.

Power Plants

Economies in a Mine Power Plant. J. A. Carruthers. Power, vol. 49, no. 19, May 13, 1919, pp. 720-722, 3 figs. Example is quoted where it is said that power plant effected reduction of 13 to 15 tons of coal per day as result of several changes in equipment.

Queensland Mining Industry

Queensland Mining Industry. Queensland Gov. Min. Jl., vol. 20, no. 226, Mar. 15, 1919, pp. 97-114, 1 fig. Annual report of Under Secretary for Mines for 1918. It includes inspection of mines, state mining and boring operations, geological survey and methods of mining gold, copper, tin, silver, lead, wolfram, bismuth, molybdenite and scheelite.

Rescue Apparatus

Digest of the First Report of the Mine Rescue Apparatus Research Committee. David Penman. Trans. Instn. Min. Engrs., vol. 56, part 4, Apr. 1919, pp. 236-260 & (discussion) pp. 260-272, 7 figs. Committee was appointed by Advisory Council to Committee of Privy Council for Scientific and Industrial Research, to inquire into types of breathing apparatus used in coal mines and by experiment to determine the advantages, limitations and defects of the several types of apparatus, their possible improvements and the advisability to standardizing.

Respirator

The Use of the Gas Mask as a Respirator. A. C. Fieldner and S. H. Katz. Chem. Engr., vol. 27, no. 4, Apr. 1919, pp. 79-83, 3 figs. Directions of uses in chemical and metallurgical industries. Warning is issued against indiscriminate use of gas masks for any and all purposes; it is observed that poisonous gases used in warfare are chemically active and therefore combine readily with absorbents of gas mask; some of the gases, however, immediately penetrate the mask when present in quantities of one or two per cent.

Ties, Steel

Steel Mine Ties. R. B. Woodworth. Coal Age, vol. 15, no. 18, May 1, 1919, pp. 814-816, 6 figs. Gain in headroom, endurance, fireproofness, scrap value, and simplicity are quoted as some of the advantages of steel tie over wood rest.

Timbering

Safe and Efficient Mine Timbering—V. R. Z. Virgin. Coal Indus., vol. 2, no. 5, May 1919, pp. 175-177, 3 figs. Removing timber from pillar workings, hanging canvas and timbering with wire rope.

See also MUNITIONS AND MILITARY ENGINEERING (Mining); MECHANICAL ENGINEERING, Handling of Materials (Ore Handling).

MINOR INDUSTRIAL MATERIALS

Antimony

Pure Antimony (Reines Antimon). E. Groschuff. Zeitschrift für anorganische & allgemeine Chemie, vol. 103, no. 3, June 21, 1918, pp. 164-188. Technical refining of metallic antimony; electrolytic refining of antimony; crystallization of metallic antimony; precipitation and purification of antimony sulfide; crystallization of antimony as tartar emetic; analytical examination of antimony; examination of commercial antimony as to impurities; analytical and physical characterization of nominally pure antimony.

Chrome

Maryland Sand Chrome Ore. Joseph T. Singewald, Jr. Economic Geology, vol. 14, no. 3, May 1919, pp. 189-197, 5 figs. Account of Chrome industry in Maryland State. Paper presented before Geological Soc. of America.

Quicksilver

The Anticlinal Theory and Some Quicksilver Deposits. William H. Emmons. Eng. & Min. Jl., vol. 107, no. 21, May 24, 1919, pp. 916-917, 2 figs. Considers theory as applicable to prospecting of areas where structure conditions are favorable.

Vanadium

Treatment of Cuprodescloizite for Extraction and Recovery of Vanadium, Lead and Copper. J. E. Conley. Chem. & Metallurgical Eng., vol. 20, no. 9, May 1, 1919, pp. 465-469. It is held that the niter cake-sulphuric acid extraction is most economical.

OIL AND GAS

Holbrook Area

Study of Oil and Gas Possibilities of the Holbrook Area. Dorsey Hager. Salt Lake Min. Rev., vol. 21, no. 3, May 15, 1919, pp. 21-25, 6 figs. Determined from examination of general stratigraphic conditions structural characteristics, notably presence or absence of folding or intrusions that might create adverse conditions for oil or gas accumulations. No positive indications of petroleum were found in this Arizona area.

Movement of Oil Through Gas

Movement of Oil and Gas Through Rocks. Victor Ziegler. Petroleum Times, vol. 1, no. 13, Apr. 5, 1919, pp. 275-277. Surface tension of water being greater than that of oil affords explanation for passage of water through smaller openings while oil occupies larger ones. (Concluded from p. 38.)

Natural Gas

Utilization and Conservation of Natural Gas. L. L. Graham. Gas Age, vol. 43, no. 9, May 1, 1919, pp. 477-478. How public-service commissions can control situation. Paper read at conference called by Public Service Commission of Pa.

Domestic and Industrial Use of Natural Gas. John Gates. Gas Age, vol. 43, no. 9, May 1, 1919, pp. 470-471. Conditions in Pittsburgh district.

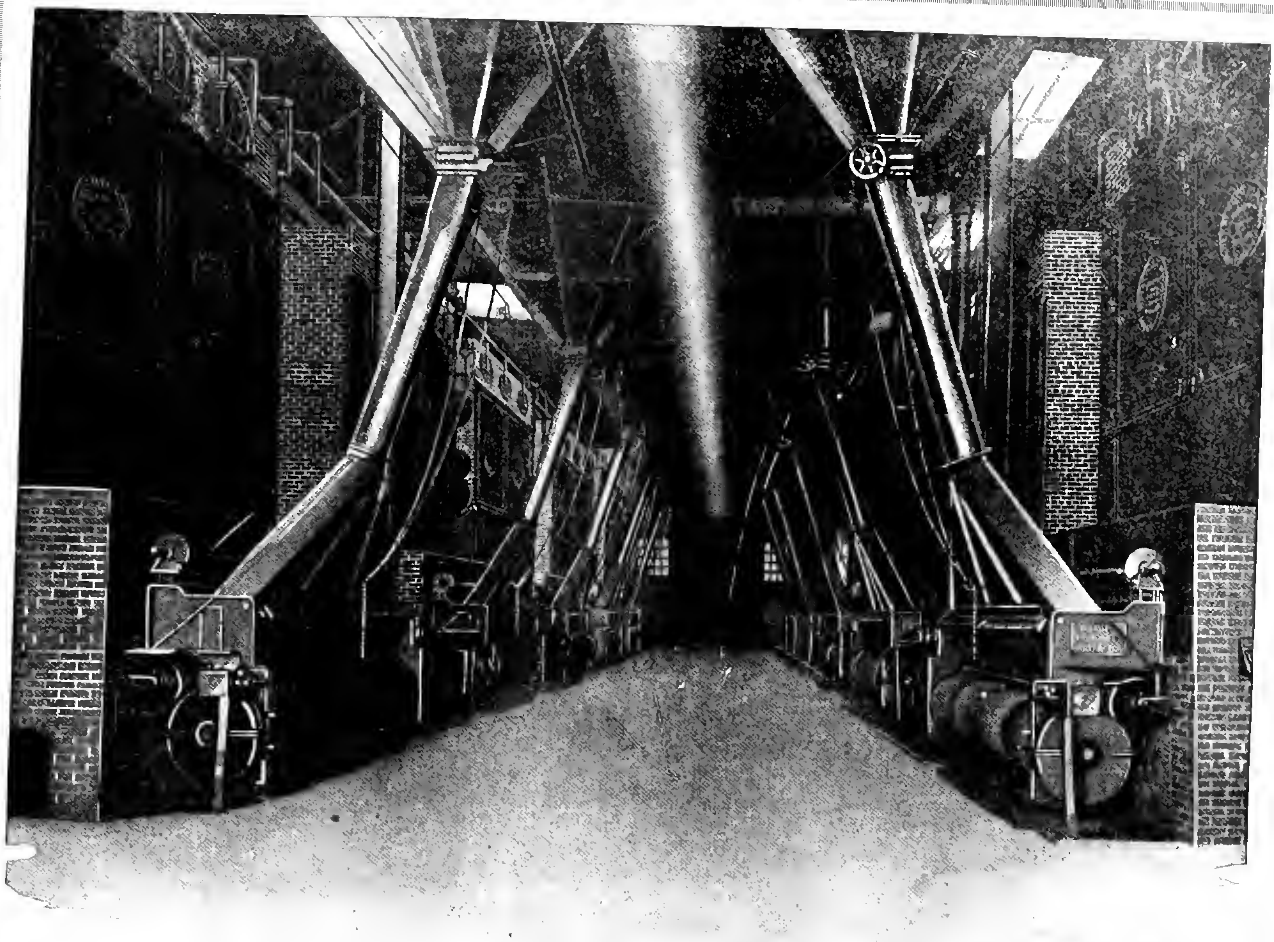
Texas

The Oil Fields of Northwestern Texas. W. L. Watts. Min. & Oil Bul., vol. 5, no. 5, Apr. 1919, pp. 255-258 and 269, 7 figs. Types of structures and petroleum geology in general. Third and concluding article. Second article appeared in Dec. 1918 issue.

PRECIOUS MINERALS

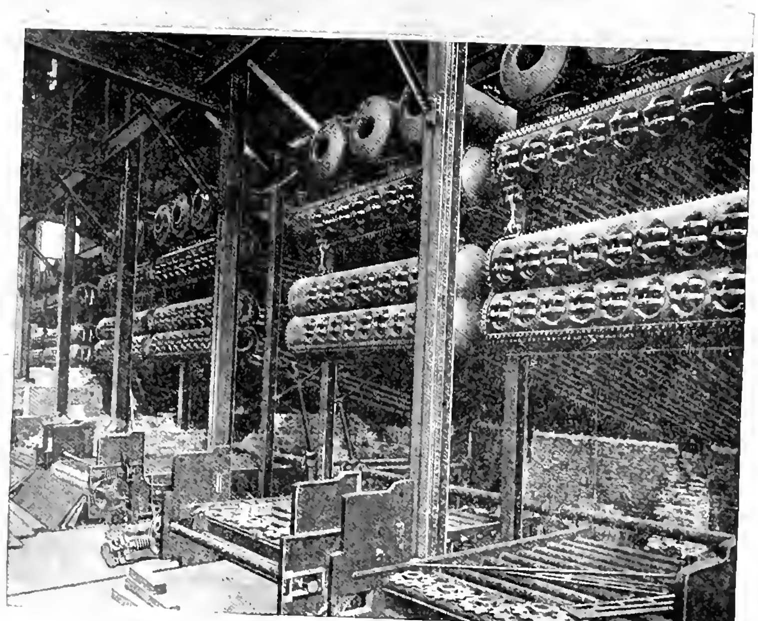
Gold Situation

Report of a Joint Committee Appointed from the Bureau of Mines and the United States Geological Survey by the Secretary of the Interior to Study the Gold Situation. Dept. of the Interior, Bur. of Mines, bul. 144, Oct. 30, 1918, 84 pp., 4 figs. Decline in gold



10,000 Horse Power
Vogt Water Tube
Boilers at Whiting
Indiana. ♦ ♦ ♦ ♦

Vogt



Let Us Figure on Your Requirements

HENRY VOGT MACHINE CO.

MANUFACTURERS

LOUISVILLE, KY.

mining is believed to be due to labor shortage and higher wages, lower efficiency of available labor and higher cost of power.

Santiago River

Gold Deposits of the Santiago River and its Zone (La riqueza aurifera del rio Santiago y de su zona), Luis Ulboa. Boletin de la Sociedad Geografica de Lima, vol. 34, Dec. 1918, pp. 94-106. Geographical history.

South Africa

Labor and Gold Mining in South Africa, Evelyn A. Walters. Eng. & Min. Jl., vol. 107, no. 21, May 24, 1919, pp. 918-922. Remedy for labor unrest lies, writer holds, in building, piece by piece, with persistence and patience, upon basis of steadily developing mutual understanding and desire to mutual good will between employer and employees.

TRANSPORTATION

India

The Carriage of Coal by Rail in India, H. Kelway-Bamber. Ry. Gaz., vol. 30, no. 16, Apr. 18, 1919, pp. 689-691, 3 figs. Gross earnings of train weighing 1400 tons and carrying coal a distance of 250 miles. (Continuation of serial.) Paper read before Indian Section Roy. Soc. Arts.

Mine Haulage

Efficiency in Mine Haulage Construction, George L. Yaste. Coal Indus., vol. 2, no. 5, May 1919, pp. 199-200. In choice of rails for roadway writer prefers to have them rather heavy than so light that it should become difficult to maintain track on account of low places between ties and at junction of rails.

Metallurgy

ALUMINUM

Alloys

Aluminum and Its Light Alloys. Dept. of Commerce, Circular of the Bur. of Standards, no. 76, Apr. 21, 1919, 120 pp., 27 figs. Deals primarily with physical properties of metal or alloy. Other features, except a few statistics of production and such as methods of manufacture, presence of impurities, etc., are discussed only in their relation to these physical properties.

Aluminum and Magnesium

The Metallurgy of Aluminum and Magnesium, H. B. Pulsifer. Salt Lake Min. Rev., vol. 21, no. 2, Apr. 30, 1919, pp. 21-25, 4 figs. Principles of electrolytic cell for producing magnesium; methods of manufacture.

Micrography

The Micrography of Aluminum and Its Alloys. D. Hanson and S. L. Archbutt. Metal Industry, vol. 14, no. 14, Apr. 4, 1919, pp. 277-283, 13 figs. Preparation of etchings, especially when metal has been cold-worked, when material is said to exhibit great readiness to become tarnished by formation of adhering coating of oxide of aluminum.

COPPER AND NICKEL

Alloys

The Properties of Some Copper Alloys, W. Rosenhain and D. Hanson. Metal Industry, vol. 14, no. 14, Apr. 4, 1919, pp. 269-272 and (discussion) pp. 272-274, 4 figs. Series prepared by Metallurgy Dept. of Nat. Physical Laboratory. Combination of high tensile strength with great ductility was aimed at in every case.

Brass and Silicon

Some Principles Involved in Melting Metals—V, Charles Vickers. Brass World, vol. 15, no. 5, May 1919, pp. 145-147, 2 figs. Adding silicon to yellow brass in order to increase fluidity of alloy so that it can be poured into thin castings.

Brass for Rolling

Notes on Alloys Used in British Brass-Rolling Mills, A. J. Franklin. Metal Indus., vol. 17, no. 5, May 1919, pp. 225-228, 1 fig. Effects of impurities, casting difficulties, hints on annealing and composition of some of the alloys.

Copper Rolling

The Metallurgy of Copper, Thomas H. A. Eastdick. Sci. Am. Supp., vol. 87, no. 2264, May 24, 1919, pp. 332-333 and pp. 335-336, 5 figs. Graphs showing effect of rolling on tensile strength and elongation under a given stress.

Slag

Copper-Smeltery Slag from the Microscopic and Chemical Point of View, C. G. Maier and G. D. Van Arsdale. Eng. & Min. Jl., vol. 107, no. 19, May 10, 1919, pp. 815-824, 40 figs. Combined misroscopical and chemical method pursued in investigations indicated that, in slags examined, copper existed in two physical forms chemically similar: (1) dissolved copper sulphide, in blast furnace and reverberatory slags and in converter or mixed slags, and (2) mechanically suspended particles of sulphide copper varying in composition from matte to Cu₂ S X Cu and in amount equal to total copper less dissolved copper.

FERROUS ALLOYS

Ferro-Manganese

Manganese Alloys in Open-Hearth Practice. Iron Age, vol. 103, no. 21, May 22, 1919, pp. 1363-1365. Use of silico-manganese recommended.

FLOTATION

Gold

Notes on Cyaniding, W. B. Blyth Min. Mag., vol. 20, no. 4, Apr. 1919, pp. 224-226. Effect of arsenic and antimony and position of flotation as regards gold metallurgy.

FURNACES

Heating and Annealing Furnaces

Heating Furnaces and Annealing Furnaces—V. W. Trinks. Blast Furnace & Steel Plant, vol. 7, no. 5, May 1919, pp. 215-217, 6 figs. Heat losses from tongue-hold, from openings around ingots, through roofs partly burned and through incomplete combusion. Examples derived from large furnaces.

IRON AND STEEL

Cast Iron

The Solubility and Stability of Iron Carbide in Cast Iron, J. A. Holden. Iron & Coal Trades Rev., vol. 98, no. 2668, Apr. 18, 1919, p. 479, 3 figs. Results of various experimenters compiled and compared.

Duplexing

Metallurgical Considerations of Duplexing—I, Richard S. McCaffery. Blast Furnace & Steel Plant, vol. 7, no. 5, May 1919, pp. 209-212. Operation of large and small Bessemer converters from viewpoint of metallurgical and physical chemistry.

Electric-Furnace Steel

Electric Furnace Steel, William K. Booth. Jl. Am. Steel Treaters Soc., vol. 1, no. 6, Mar. 1919, pp. 207-214, 6 figs. Characteristics of Booth-Hall electric furnace. General principle of design is hearth which becomes conductive of electricity when hot, and use of auxiliary electrode which acts as a return for the electric current until the hearth becomes heated and conductive.

Making Electric Steel for Roller Bearings. Machy. (Lond.), vol. 14, no. 344, May 1, 1919, pp. 131-137, 11 figs. Practice of Timken Roller Bearing Co., Canton, Ohio, in operating Héroult electric furnaces forging ingots, rolling billets and cold-drawing steel into solid bars and seamless tubing.

Flaky Fractures

Flaky Fractures and Their Possible Elimination, Haakon Styri. Chem. & Metallurgical Eng., vol. 20, no. 9, May 1, 1919, pp. 478-483, 1 fig. Review of literature bearing upon oxides and other inclusions in steel, together with application of principles of physical chemistry to conditions in a steel melt.

Graphitization

Graphitisation in Iron-Carbon Alloys, Kunii-chi Tawara and Genshichi Asahara. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 14, 16 pp., 4 figs., also abstracted in Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 578-579, 2 figs. View is held that in fluid alloys there exist atoms of free carbon; these free-carbon items may serve as nuclei for the graphitization when conditions are favorable.

Hardening

The Hardening of Steel, H. C. H. Carpenter. Engineering, vol. 107, nos. 2776 and 2777, Mar. 14 & 21, 1919, pp. 340-341 and 386-390, 18 figs. Exposition of various views as to scientific explanation of this property. Discourse delivered at Roy. Instn.

The Experimental Investigation of the Influence of the Rate of Cooling on the Hardening of Carbon Steels, A. M. Portevin and M. Garvin. Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 599-607, 25 figs. (Abridged.) Reported that with temperature falling regularly formation of troostite corresponds with rapid transformation at high temperature (about 650 deg. cent.), and that of martensite with relatively slow transformation and at about 300 deg. cent. and under. Paper read before Iron & Steel Inst.

High-Speed Steel

The Manufacture and Working of High-Speed Steel, J. H. Andrew and G. W. Green. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 1, 32 pp., 40 figs. Also abstracted in Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 588-590, 2 figs. Investigation of various forging operations of cogging, rolling, etc., disclosed, in opinion of writers, that for efficient forging temperatures must be used which are appreciably higher than those which are generally accepted as correct. Also photomicrographs are interpreted as showing that whether reduction is effected by rolling or hammering, or a combination of both, no difference is produced in the microstructure of the steel.

The Molecular Constitutions of High-Speed Tool Steels and Their Correlations with Lathe Efficiencies, John Oliver Arnold. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 2, 24 pp., 5 figs. Experiments to ascertain compositions of the carbides of chromium, vanadium, tungsten, and molybdenum and to examine electrolytic differential analyses of carbides and tungstide.

Ingot Production

Safeguarding Steel Ingot Production. Raw Material, vol. 1, no. 2, Apr. 1919, pp. 138-143, 6 figs. Indicates how some of methods of ingot production can be improved wherever steel price justifies expense of changing established practice. (To be continued.)

Lime in Open Hearth

Deoxidation, and the Influence of Lime on Equilibrium in the Acid Open-Hearth Furnace, B. Yaneske. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 17, 16 pp. Also in Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 576-578. While writer admits that for certain classes of steel such as that required for ship and similar plates it is unnecessary to obtain a very highly deoxidized bath, yet he considers that for special steel, particularly nickel-chrome, which has to undergo severe mechanical tests, forging and machining operations, it is essential that such a condition of the bath be obtained before the finishing alloys are added.

Liquidus

Note on the Liquidus in the Iron-Carbon Diagram, G. Cesaro. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 4, 9 pp., 1 fig. Based on deduction from experiments by Carpenter and Keeling, writer endeavors to ascertain cause of curve joining points at which molten iron-carbon alloys commence to solidify.

Malleable Cast Iron

Effects of Phosphorus on Malleable Cast Iron, J. H. Teng. Foundry, vol. 47, no. 320, Apr. 1, 1919, pp. 151-156, 9 figs. Curves indicating effect of increasing phosphorus on tensile properties of both the pure-iron series and the common-iron series. From paper presented before Iron & Steel Inst.

Manganese in Open Hearth

The Use of Manganese Alloys in Open-Hearth Steel Practice, Samuel L. Hoyt. Metal Trades, vol. 10, no. 5, May 1919, pp. 227-230, 1 fig. Investigation to determine (1) condition in open-hearth practice that lead to conservation of manganese both during working of heat and in making final addition; (2) satisfactory metallurgical conditions for use of manganese in form of low-grade or special alloys, and (3) effect on finished steel, both as to quality and "condition" of various methods and processes studied. From Bul. no. 11 of War Minerals Investigation Series, U. S. Bur Mines.

Metallurgy

Modern Steel Metallurgy, Chas. H. F. Bagley. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 3, 49 pp. Also Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 565-571. Method of calculating consumption of materials and technical results in manufacture of steel from any kind of pig iron by any standard process.

Quenching

The formation of Troostite at Low Temperature in Carbon-Steels and the Influence of the Emersion Temperature in Double Quenching (La formation de la troostite à bassee température dans les aciers au carbone et l'Influ-

DUMPS

that operate from the side make the work of cleaning easier and keep the boiler on the line no matter how poor the fuel.

TYPE "E" STOKERS

DUMP FROM THE SIDE

SEATTLE, WASH. SALT LAKE CITY, UTAH ALBANY, N. Y.
OMAHA, NEB. TAYLOR ENGINEERING CO., VANCOUVER, B. C.

ence de la température d'émersion dans les trempes interrompues), M. Portevin and M. Garvin. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 14, Apr. 7, 1919, pp. 731-733. Concluded from experimental investigations that in vicinity of critical quenching velocity, troostite will form even after cooling to 450 deg. cent., such formation being always accompanied with a pronounced characteristic recalescence.

Refractories

See Refractories, under MECHANICAL ENGINEERING.

Rolling Mills

See Mechanical Processes, (Steel Mills), under MECHANICAL ENGINEERING.

Slag

The Acid Hearth and Slag, J. H. Whiteley and A. F. Hallimond. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 16, 44 pp., 29 figs. Also abstracted in Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 579-583, 3 figs. Microstructure of slags, structure of slowly cooled acid slags and reactions occurring in molten slag during process. From observations and experiments.

Transformations in Iron

On the Non-Allotropic Nature of the A2 Transformation in Iron, Kôtarô Honda. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 9, 8 pp., 3 figs. Also abstracted in Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 575-576. Reported experiments evidenced three transformations, A2, A3 and A4, in the case of pure iron; last two are said to be allotropic transformations, while the first cannot properly be so called.

MICROPHOTOGRAPHS

Macro-Etching and Printing

Macro-Etching and Macro-Printing, J. C. W. Humfrey. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 10, 14 pp., 12 figs. Also abstracted in Iron & Coal Trades Rev., vol. 98, no. 2671, May 9, 1919, pp. 607-609, 4 figs. Writer's etching reagent used in course of investigation into flow of steel during process of punching and drawing a shell blank, was prepared by addition of hydrochloric acid to Heyn's reagent.

NON-FERROUS ALLOYS

Metallography

Metallography Applied to Nonferrous Metals—IV, Ernest J. Davis. Foundry, vol. 47, no. 6 & 7, May 1 & 15, 1919, pp. 263-266 & 304-307, 15 figs. Equilibrium diagram of copper-aluminum, aluminum-zinc and aluminum-magnesium series, and photomicrographs of various alloys.

OCCLUDED GASES

Hydrogen

The Occlusion of Hydrogen by the Metallic Elements and Its Relation to Magnetic Properties, Donald P. Smith. Jl. Physical Chemistry, vol. 23, no. 3, Mar. 1919, pp. 186-200, 1 fig. From review of literature it is deduced that resulting alloys are to be distinguished from other types of binary hydrogen compounds and that metals which form the alloys probably occupy a definite region in the periodic table of Werner.

Aeronautics

AIRCRAFT

Lift of Airships

Lighter-than-Air Craft, T. R. Cave-Browne-Cave. Aeronautics, vol. 16, no. 285, Apr. 3, 1919, pp. 365-371, 4 figs. Technical study of factors governing variation of lift of an airship and its significance in design of envelope. Paper read before Roy. Aeronautical Soc.

Non-Rigid Airships

The Development of Airship Construction, C. I. R. Campbell. Engineer, vol. 127, no. 3303, Apr. 18, 1919, pp. 384-386, 3 figs. General dimensions and dates of three typical non-rigid airships, Zodiac, Parseval and Astra types. Paper read before Instn. Naval Architects.

Rigid Airships

Rigid Airship Design: The Tension in the Diagonal Bracing Wires, E. H. Lewitt. Aeronautics, vol. 16, no. 287, Apr. 17, 1919, pp. 402-403, 2 figs. Formula based on assumption that ship bends about a neutral axis, that longitudinal girders take the bending stresses only, while diagonal bracing wires take all the shear, and that all loads are concentrated at transverse frames.

APPLICATIONS

Air Navigation Regulations

Air Navigation, H. E. Wimperis. Flight, vol. 11, no. 19, May 8, 1919, pp. 600-604, 10 figs. Technical problems in air navigation, similar to those presented by sea navigation and manner of solving same. Paper read before Roy. Aeronautical Soc.

Air Navigation Regulations. Flight, vol. 11, no. 19, May 8, 1919, pp. 608-615, 2 figs. Legislation concerning conditions of flying, aerodromes, safety provisions, licensing of personnel, lights and signals, registration and nationality marks.

Commercial Transportation

Commercial Transportation and High-Speed Services by Air, G. Holt Thomas. Aeronautics, vol. 16, no. 287, Apr. 17, 1919, pp. 404-405. Visualizes trade conditions when "there will be no place on the earth's surface more than four days' journey from London by air."

Air Transports (Aéro-Transports), Ernest Archdeacon. L'Aérophile, vol. 27, nos. 3-4, Feb. 1-15, 1919, pp. 33-37, 3 figs. Analysis of types developed during war which indicate possibilities of commercial utilization for air service.

Latin-American Republics

Aviation as a Solution of the Economic and Sociological Problems of Latin American Republics (Lo que puede hacer la aviacion en pro de la solucion de los problemas economicos y sociologicos de las republicas latinoamericanas), Henry Woodhouse. Flying, vol. 8, no. 4, May 1919, pp. 350-351 & 374. Argues that since lack of adequate means of transportation has prevented growth of Latin America, its development by establishing air routes will solve problem.

AUXILIARY SERVICE

Air Fans

Air Fans for Driving Generators on Airplanes, G. Francis Gray, John W. Reed and P. N. Elderkin. Mech. Eng., vol. 41, no. 6, June 1919, pp. 527-530, 11 figs. Difficulty of problem in designing is represented as having been the production of fan which was turned at constant speed in air streams of widely varying speeds set up by airplane in flight. Paper for June meeting of A.S.M.E.

Navigation Apparatus

Determining True Course in Aerial Navigation (Indicateur-jalonneur de route pour la navigation aérienne à l'estime), L. Dunoyer. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 14, Apr. 7, 1919, pp. 728-729. To simplify composition of triangle of velocities a system is suggested which involves placing on pilot's chart at place of departure an indicator having concentric circles whose radii are proportional to distances made under wind of 2, 4, 6 .... meters per sec., and at place terminus of voyage a similar indicator in which the radii of concentric circles are proportional to distances travelled by airplane in calm weather. Their operation is illustrated by examples.

Telephone Apparatus, Radio

Aeroplane Radio Telephone Apparatus, Edgar H. Felix. Aerial Age, vol. 9, no. 8, May 5, 1919, pp. 397-399, 10 figs. Types of microphones, headgear and generators developed by Signal Corps.

DESIGN

Aerofoil Design

Some Future Possibilities of Aerofoil Design, W. E. Astin. Flight, vol. 11, no. 16, Apr. 17, 1919, pp. 506-509, 7 figs. Considers possible that rigid wings will not persist, but will in time be replaced by wings which may be of variable area, of variable angle of incidence, variable camber, or again of any suitable combination of these variables.

Commercial Engines

Machines for Commerce and Pleasure. Aeronautics, vol. 16, no. 286, Apr. 10, 1919, pp. 380-381, 3 figs. Graham White Co., Ltd., has decided on seven types: instructional machine, Bantam sporting single-seater, express airmail machine, four-seater aero-limousine, five-seater aero-limousine, 24-seater passenger machine, and Dominions-type machine.

Radius of Action

Air Mileage of Aeroplanes Intended for Long Distances and for Transport, J. Dennis Coales. Engineering, vol. 107, no. 2783, May 2, 1919, pp. 557-560, 6 figs. Technical study of limitations with reference to problem of transatlantic flight. (To be continued.)

ENGINES

Cooling

The Cooling of Aero Engines. Autocar, vol. 42, no. 1227, Apr. 26, 1919, pp. 609-612, 9 figs. Physical conditions of the atmosphere to which engine must adapt itself. Discusses means being adopted for preventing overcooling of front valves.

Design

The Design of Airplane Engines—V, John Wallace. Automotive Eng., vol. 4, no. 4, Apr. 1919, pp. 166-168, 11 figs. Crank-effort diagram; calculation of inertia forces of reciprocating mass. (To be continued.)

Hispano-Suiza

Hispano-Suiza Motors (Les moteurs Hispano-Suiza). L'Aérophile, vol. 27, no. 5-6, Mar. 1-15, 1919, pp. 78-81, 8 figs. Five types considered are: 150 hp., 180 hp., 200 hp., 220 hp., and 300 hp. (To be continued.)

King-Bugatti Engine

King-Bugatti 16-Cylinder Aero Engine—II. Automotive Industries, vol. 11, no. 18, May 1, 1919, pp. 956-959, and 986, 7 figs. Consists virtually of two 8-cyl. all-in-line engines mounted on common crankcase and geared to common propeller shaft; designed to permit a 37-mm. cannon to shoot through hollow propeller shaft.

Liberty Engine

Mechanical Details of the Liberty Engine—III. Automotive Eng., vol. 4, no. 4, Apr. 1919, pp. 178-179 and 192. Specifications of both the cast-iron cylinder forms for tank use and the steel cylinder type with sheet-metal water jackets for airplane power plants.

Maybach Engine

Details of the 300-Horsepower Maybach Airplane Engine. Automotive Eng., vol. 4, no. 4, Apr. 1919, pp. 169-173, 10 figs. Mechanical construction and design features. Cylinders, crankcase and shaft, pistons and wrist pins. (To be continued.)

Puma Engine

The Siddeley-Deasy "Puma" Aero Engine. Aerial Age, vol. 9, no. 9, May 12, 1919, pp. 441-442 and 453, 4 figs. Engine has 6 cylinders; outstanding features claimed are special construction of cylinders and arrangement of mechanism actuating valves, these features being designed to facilitate dismantling and erection for repairs.

Superchargers

Maintaining Constant Pressure Before the Carburetors of Aero Engines Regardless of the Altitude, Leslie V. Spencer. Aerial Age vol. 9, no. 8, May 5, 1919, pp. 387-389, 7 figs. Mechanical features of Moss and Sherbondy turbo-superchargers. (Concluded.)

Zeitlin Engine

The Zeitlin Aero-Engine. Engineer, vol. 127 no. 3304, Apr. 25, 1919, pp. 408-410, 10 figs Nine-cylinder rotary 220-hp. engine. Differ fundamentally from other motors in that pis ton stroke is not of uniform length in eac of the four movements constituting a complet cycle.

See also MECHANICAL ENGINEERING Mechanical Processes (Liberty Motor Port Production of.)

INSTRUMENTS

Anemometers

Design of Pressure Plate Anemometers, H. Powell. Aviation, vol. 6, no. 7, May 1919, pp. 374-375, 3 figs. Technical points design. Writer takes up case of constructi instrument to give direct readings witho making it necessary to have recourse to tri and error methods.

MATERIALS OF CONSTRUCTION

Glues

The Manufacture and Use of Glues in Aer plane Construction, B. C. Boulton. Aer Age, vol. 9, nos. 8 & 9, May 5 & 12, 1919, 390 and 395-396, and 451-453, 2 figs. Bas upon technical reports prepared for Bur. A craft Production. Factors affecting quality casein; Bur. of Aircraft Production specific tion for glues.

Veneers

Veneer Body Construction. Aviation, vol. 6, no. 8, May 15, 1919, pp. 434-436, 3 figs. Results of investigations conducted at McCook Field in endeavor to develop satisfactory veneer bodies of USC-2 and USXB-1 combat planes. (To be continued.)

METEOROLOGY

Cyclone Compression

Examples of "Cyclone Compression" (Sur quelques exemples de "compression de cyclone"), Gabriel Guilbert. Comptes rendus des séances de l'Académie des Sciences, vol. 168 no. 13, Mar. 31, 1919, pp. 691-693. Cases quoted in substantiation of rule: Depressed region surrounded with converging strong winds shows maximum barometric compression in center.

MODELS

Aeroplanes

Model Aeroplanes—XXIII. F. J. Camm. Aeronautics, vol. 16, no. 285, Apr. 3, 1919, p. 363, 6 figs. Built-up plane: covered with proofed transparent silk. Illustrations indicate construction details.

Elementary Aeronautics and Model Notes. John F. McMahon. Aerial Age, vol. 9, no. 9, May 12, 1919, p. 457, 1 fig. Model in which regular tested wing curve is used.

Air Screws

Model Aeroplanes—XXIV. F. J. Camm. Aeronautics, vol. 16, no. 287, Apr. 17, 1919, p. 409, 4 figs. Carving model airscrews.

Speed Models

Elementary Aeronautics and Model Notes. John F. McMahon. Aerial Age, vol. 9, no. 8, May 5, 1919, p. 403, 2 figs. Speed model said to have developed speed of 55 miles per hour.

PLANES

B. A. T.

The B. A. T. Four-Seater Biplane. Flight, vol. 11, no. 16, Apr. 17, 1919, pp. 494-498, 11 figs. Designed for commercial work—either passengers or carrying mail; provides accommodation for four passengers besides pilot.

Curtis M-F Flying Boat

Curtiss M-F Flying Boat. Aerial Age, vol. 9, no. 8, May 5, 1919, pp. 384-385, 5 figs. Equipped with 8-cyl., 4-stroke cycle water-cooled V-type engine, rated at 100 hp. at 1400 r.p.m.; bore and stroke $4\frac{1}{2}$ in. by 5 in.

Halberstadt

The Halberstadt Two-Seater Fighter. Aviation, vol. 6, no. 7, May 1, 1919, pp. 384-386, 11 figs. Constructional features.

Lepere

The Lepere Two-Seater Fighter. Aviation, vol. 6, no. 8, May 15, 1919, pp. 426-429, 8 figs. Belongs to class of DeH.-4 and Bristol type. One peculiarity of design is that there are no incidence or stagger wires in the plane, these being replaced by a system of portal-framed struts.

Pfalz

The Pfalz (D XII) Single-Seater Fighter. Flight, vol. 11, no. 17, Apr. 24, 1919, pp. 528-533, 16 figs. This airplane was brought down near Dury on Sept. 15, 1918. Report covering design and details issued by Technical Dept. (Aircraft Production) Ministry of Munitions.

Tarrant Triplane

The Tarrant Giant Triplane. Flight, vol. 11, no. 19, May 8, 1919, pp. 592-593, 2 figs. Power plant consists of Napier "Lion" engines, four of which are mounted on bottom plane, the other two being placed between the middle and the top plane and driving tractor screws. Warren type of girder has been adapted in regard to wood construction.

Torpedoplane

The Torpedoplane, the New Weapon which Promises to Revolutionize Naval Tactics. Henry Woodhouse. U. S. Naval Inst., Proc., vol. 45, no. 5, May 1919, pp. 743-752. Constructed for dropping torpedoes from airplanes.

PROPELLERS

Variable Pitch Propeller

Pilot Motor Variable Pitch Propeller. Alfred Vischer, Jr. Aviation, vol. 6, no. 7, May 1, 1919, pp. 380-381, 3 figs. SCR-73 synchronous rotary-gap transmitter designed and developed to be adjustable to nine wave lengths supplemented by five notes obtained from interchangeable-gap rotors to prevent interference and to aid in identification.

PRODUCTION

Fire Hazard

Features of Fire Hazard in Airplane Manufacture. W. D. Milne. Quarterly of the Nat. Fire Protection Assn., vol. 12, no. 4, Apr. 1919, pp. 345-352. Notes on prominent fire hazards as observed by writer in various airplane factories; he advocates incorporating in plans for these plants measures necessary for their protection against fire.

National Aeroplane Factory, England

National Aeroplane Factory Near Manchester. Engineer, vol. 127, no. 3301, Apr. 4, 1919, pp. 422-424, 10 figs. on supp. plate. Factory covers area of 15 acres and comprises assembling and erection shop, woodworking shop, timber drying shed for spruce conditioning and two ash-drying plants.

Naval Aircraft Factory, Philadelphia

Aeroplane Construction, F. G. Coburn. Jl. Engrs. Club, Philadelphia, vol. 36-4, no. 175, Apr. 1919, pp. 121-126, 6 figs. Brief account of construction and development of Naval Aircraft Factory at Philadelphia Navy Yard.

TESTING

Engine Trials

The Analysis of Engine Trials. Automobile Engr., vol. 9, no. 126, May 1919, pp. 134-136, 9 figs. Empirical methods of calculation for analyzing results of aero-engine trials, particularly where tests have obviously been faulty or incomplete.

Full-Scale Experiments

Full Scale Aeroplane Experiments. W. S. Farren. Aeronautical Jl., vol. 23, no. 98, Feb. 1919, pp. 34-63, 14 figs. Formulæ derived from model experiments cannot be employed in designing calculations, it is stated, without first testing their validity in full-scale experiments.

TRANSATLANTIC FLIGHT

Navy (U. S.) Fliers

The Navy's Trans-Atlantic Fliers. Motor Boat, vol. 16, no. 10, May 25, 1919, pp. 5-7, 5 figs. Weights and principal dimensions.

Winds

Trans-Atlantic Flight and Meteorology. Willis Ray Gregg. Aviation, vol. 6, no. 7, May 1, 1919, pp. 370-372, 1 fig. Wind velocity and direction as affecting Newfoundland-Ireland and Newfoundland-Labrador-Greenland-Scotland routes. Paper read before Phil. Soc. of Washington.

VARIA

Aviators, Physiology

The Physiology of the Aviator. Yandell Henderson. Science, vol. 49, no. 1271, May 9, 1919, pp. 431-441. Development of this branch of science during the war and account of the principles laid down from experience.

Aviators, Tests of

Psycho-Physical Tests of Aviators. George M. Stratton. Sci. Monthly, vol. 8, no. 5, May 1919, pp. 421-426. Stress is laid upon two qualifications, viz.: coolness and power to make rapid decisions.

Camera, Aero

A New Aero Camera. Aeronautics, vol. 16, no. 286, Apr. 10, 1919, p. 389, 2 figs. Taking photograph, moving exposed plate out of position, resetting camera shutter and moving up of fresh plate into position performed by one movement.

Mapping, Aero

Methods Used in Aero-Photographic Mapping. Eng. News-Rec., vol. 82, no. 21, May 22, 1919, pp. 1000-1004, 8 figs. Outgrowth of experience in use of panoramic camera in Alaska with exposition of principles on transforming camera. From Geographical Rev.

Present Status of Photographic Mapping from the Air. J. B. Mertie, Jr. Eng. News-Rec., vol. 82, no. 21, May 22, 1919, pp. 996-999. Airplane mapping is considered possible and practicable, but it is observed that two great problems, horizontalization of camera and effects of surface relief, must be solved.

Marine Engineering

AUXILIARY MACHINERY

Anchors

New Type of Anchor. Iron Age, vol. 103, no. 19, May 8, 1919, pp. 1225-1226, 4 figs. Allison cast-steel product with spoon-shaped flukes.

Compasses

The Gyro Compass. An Essential Navigation Instrument. M. R. Lott. Monthly Jl., Utah Soc. of Engrs., vol. 5, no. 2, Feb. 1919, pp. 28-41, 8 figs. Points of difference between a gyro-compass and a magnetic compass.

Electrical Auxiliaries

Merchant Marine Electrical Auxiliaries. Walter E. Thau. Jl. Am. Soc. Marine Draftsmen, vol. 5, no. 4, Jan. 1919, pp. 55-59, 5 figs. Advantages claimed for electrical appliances over steam appliances are economy, flexibility, lessening of noise and greater reliability.

Propellers

Propeller Patterns. Machy. (Lond.), vol. 14, no. 344, May 1, 1919, pp. 125-129, 8 figs. Methods of laying out propeller patterns, assembling different sections and working blades to required form.

Investigations into the Causes of Corrosion or Erosion of Propellers. Charles A. Parsons and Stanley S. Cook. Engineering, vol. 107, no. 2781, Apr. 18, 1919, pp. 515-519, 21 figs., also Shipbuilding & Shipping Rec., vol. 13, no. 16, April 17, 1919, pp. 494-495, and Engineer, vol. 127, no. 3301, Apr. 4, 1919, pp. 427-428. Result of investigation on nature of surface and state of initial stresses in blades under working conditions; impingement of water at high velocity; cavitation; water hammer produced by vortex cavities. Paper read before Instn. Naval Architects.

SHIPS

Boilers

The Work of the British Marine Engineering Design and Construction Committee, A. E. Seaton. Engineering, vol. 107, no. 2781, Apr. 18, 1919, pp. 519-522, and Shipbuilding & Shipping Rec., vol. 13, no. 16, Apr. 17, 1919, pp. 483-484. Object of committee was unification of all rules which govern design and construction of all marine machinery, especially of that pertaining to boilers. Paper read before Instn. Naval Architects.

Cast-Steel Ship

The Cast-Steel Ship Development, Myron E. Hill. Iron Age, vol. 103, no. 21, May 22, 1919, pp. 1351-1352, 2 figs. Standard units cast in sand, assembled in position and automatically welded.

Coastal Motor Boats

Coastal Motor Boats for the Navy. Engineer, vol. 127, no. 3303, Apr. 18, 1919, pp. 369-371, 3 figs. Design aimed at smallest possible dimensions consistent with carrying of torpedo, speed of at least 30 knots and full capacity for wide radius of action.

The Mysterious "C. M. B.'s" Motor Boat, vol. 16, no. 10, May 25, 1919, pp. 8-9, 4 figs. British 55-ft. coastal motor boat designed to run at high speed and to withstand hard sea work, carries two torpedoes which are discharged over stern.

Compartment Designs of Hull

Italian Two-Floodable Compartment Cargo Steamers, Salvatore Orlando. Engineering, vol. 107, no. 2782, Apr. 25, 1919, pp. 533-537, 9 figs. Design to permit keeping ship afloat after torpedo explosion, according to specifications proposed by engineers and technical men assembled in Genoa on August 18, 1917, to examine from a technical standpoint the urgent question of reconstruction of mercantile fleet and conservation of remaining vessels. Paper read before Instn. Naval Architects.

Protection of Freight Steamers (Per una maggiore difesa del naviglio da carico), Mario Taddei. Rivista Marittima, vol. 51, no. 11, Nov. 1918, pp. 187-206, 2 figs. Technical remarks on compartment designs of hull.

Electric Propulsion

Electric Drive on Merchant Ships. W. L. R. Emmet. Instn. Mar. Eng., vol. 24, no. 5, May 1919, pp. 335-337. Electric propulsion of single-screw cargo vessel proposed.

DO YOU KNOW
what
BADGER SERVICE
means, when applied to the
Re-Cooling of
Condensing Water?
ASK US TODAY—and we will show you that we have the most economical and efficient system of cooling water by sprays, for condensers, water jackets or transformers.
WRITE FOR OUR BULLETIN NO. 101—and you will learn how the Badger System of Cooling Water with sprays will reduce power plant operating costs, save fuel, and meet the demands of any industry requiring an abundant supply of cold water.
WHY NOT ACCEPT OUR SUGGESTION—and consult with able specialists—men who have been real pioneers in the development of spray cooling systems and who are qualified to solve any water cooling problems.
All Badger Spray Cooling Equipment is constructed in our own shops with the same careful workmanship and best materials that have always been used for 77 years, in the establishment of our enviable reputation.
E. B. Badger & Sons Co.
American Spray Dept.
67 Pitts St.
Boston, Mass., U. S. A.

Electric Drive from a Military Point of View, S. M. Robinson. Mar. Eng. & Can. Merchant Service Guild Rev., vol. 9, no. 4, Apr. 1919, pp. 137-138. Based on technical considerations and performance of S. S. "New Mexico."

Merchant Shipbuilding

Some Recent Developments Towards a Simplification of Merchant Ship Construction, Eustace Tennyson d'Eycourt and Thomas Graham. Engineering, vol. 107, nos. 2781 & 2782, Apr. 18 & 25, 1919, pp. 503-505 and 554-556, 16 figs., also Shipbuilding & Shipping Rec., vol. 13, no. 16, Apr. 17, 1919, pp. 488-493, 17 figs. Design was intended to fulfill three conditions: (1) employment of labor unaccustomed to shipbuilding, (2) construction which would fully avail itself of such labor, and (3) process of obtaining parts of ship from various sources of supply and subsequently assembling such parts at the building berths. Paper read before Instn. Naval Architects.

Model Experiments

Some Experiments on Full Cargo Ship Models, James Semple. Shipbuilding & Shipping Rec., vol. 13, no. 16, Apr. 17, 1919, pp. 495-497, 5 figs. Results of experiments made in order to determine effect on performance (1) of fullness, and (2) of longitudinal distribution of displacement. Paper read before Instn. Naval Architects.

Model Experiments on the Effect of Beam on the Resistance of Mercantile Ship Forms, J. L. Kent. Engineering, vol. 107, no. 2782, Apr. 25, 1919, pp. 550-553, 11 figs., also Shipbuilding and Shipping Rec., vol. 13, no. 16, Apr. 17, 1919, pp. 501-503. Research on effect upon resistance of change in maximum beam, carried out at William Froude National Tank. Paper read before Instn. Naval Architects.

Speed, Cost of

On the Great Cost of High Speed, Sidney Graves Koon. Int. Mar. Eng., vol. 24, no. 5, May 1919, pp. 357-359, 1 fig. Analysis of relative costs in power for moderate increases in speed in slow- and high-speed vessels.

Stability of Ships

Stability of Ships, George Nicol. Shipbuilding & Shipping Rec., vol. 13, no. 18, May 1, 1919, pp. 562-564, 7 figs. Method of obtaining cross curves of stability by employment of longitudinal sections. Paper read before Instn. Engrs. & Shipbuilders in Scotland.

Submarine Chasers

The 110-Foot Submarine Chasers and Eagle Boats, J. A. Furer, U. S. Naval Instn. Proc., vol. 45, no. 5, May 1919, pp. 753-767. How British Admiralty solved problem of providing effective patrol boats for war zone and for combating activity of submarine.

United States 110-Foot Submarine Chasers, R. P. Sanborn. Int. Mar. Eng., vol. 24, no. 5, May 1919, pp. 337-343, 10 figs. Construction, equipment and engineering data, also part this type of naval vessel played in the war.

Submarines

Below Deck on a U-Boat, Warren O. Rogers. Power, vol. 49, no. 20, May 20, 1919, pp. 784-787, 5 figs. Notes on engine room and torpedo room.

Tankers

The World's Largest Oil Tanker. Petroleum Times, vol. 1, no. 14, Apr. 12, 1919, pp. 289-292, 5 figs. Vessel has d.w. carrying capacity of over 18,000 tons.

Tonnage

The Tonnage of Modern Steamships, A. T. Wall. Engineering, vol. 107, no. 2782, Apr. 25, 1919, pp. 549-550, also Shipbuilding & Shipping Rec., vol. 13, no. 16, Apr. 17, 1919, pp. 479-481. Effect of recent legislation on modern machinery on tonnage measurement. Paper read before Instn. Naval Architects.

Turbine Machinery

Turbine Machinery for Standard Ships. Engineer, vol. 127, no. 3303, Apr. 18, 1919, pp. 371-373, 11 figs., partly on supp. plate. Two Turbines driving one screw propeller through toothed reduction gearing considered as most economical design because it is said that by splitting up power between two units, turbines can be designed to utilize high vacuum without making machines unduly large or adopting inconveniently high speed.

Marine Geared Turbines Have Shown Great Economy and Efficiency, William H. Easton. Marine News, vol. 5, no. 12, May 1919, pp. 110-111, 5 figs. Discussion of relative advantages of turbines and reciprocating engines.

Modern Ships

3500-Ton D. W. Auxiliary Schooners Built for France. Rudder, vol. 35, no. 5, May 1919, pp. 244-247, 5 figs. Built of Oregon fir in long lengths. Machinery consists of two triple-expansion steam engines and two Roberts water-tube boilers with 1800 sq. ft. heating surface.

The Uses of Wood, Hu Maxwell. Am. Forestry, vol. 25, no. 304, Apr. 1919, pp. 973-983, 21 figs. Wooden boats and their manufacture. Twentieth article.

See also MUNITIONS AND MILITARY ENGINEERING (Battleships); MECHANICAL ENGINEERING, Foundries (Ship Work).

TERMINALS

Coaling

Coaling Ships Mechanically—II, Wilbur M. Stone. Coal Trade Jl., vol. 50, no. 19, May 7, 1919, pp. 527-529, 4 figs. Trimming mechanism, driving motor and reduction gearing. Concluding article.

Shanghai

The Port of Shanghai, Paul Page Whitman. Pac. Mar. Rev., vol. 16, no. 5, May 1919, pp. 71-77, 17 figs. General description. Maritime customs report for 1917 shows foreign trade of this port to be a little over one-half billion dollars.

Wharf Equipment

Wharf Equipment, Roy S. MacElwee. Professional Memoirs, Corps Engrs., U. S. Army & Engr. Dept., vol. 10, no. 54, Nov.-Dec., 1918, pp. 820-840, 12 figs. Determining size of transit shed. Reference is made to conditions in several of principal ports in the world.

See also CIVIL ENGINEERING, Harbors.

YARDS

British Columbia

British Columbia's Part in Ship Programme, A. F. Menzies. Can. Machy., vol. 20, no. 26, Dec. 26, 1918, pp. 722-729, 15 figs. Program undertaken by Imperial Munitions Board Wooden Shipbuilding Dept. report completed and to have resulted in addition of 27 wooden steamers of total d.w. capacity of over 75,000 tons.

Castings

Steel Foundry to Cast Ships, E. C. Kreutzberg. Mar. Rev., vol. 49, no. 6, June 1919, pp. 269-271, 4 figs. Methods of Cast Steel Ship Corp., New York, for casting component parts of ships. Parts are afterwards permanently joined by welding.

Concrete Car Floats

New Concrete Shipyard on Lake Erie. Int. Mar. Eng., vol. 24, no. 5, May 1919, pp. 352-356, 14 figs. Method of constructing concrete car floats.

Concrete Shipyards, British

British Concrete Shipyards, W. Noble Twelvetrees. Engineering, vol. 107, no. 2776, Mar. 14, 1919, pp. 334-338, 21 figs. partly on separate plates. Two yards are dealt with, (1) Brentford, of limited capacity, as only one vessel not exceeding 150 ft. can be built there at a time; and (2) Rochford, equipment of which provides for simultaneous construction of three vessels up to nearly 200 ft. in length.

Hog Island Shipyard

The Electrical Features of Hog Island Shipyard, H. W. Osgood. Jl Engrs. Club, Philadelphia, vol. 36-5, no. 174, May 1919, pp. 165-173, 8 figs. Problem was to anticipate where and in what amount electric service would be required in yard, which was expected to grow up in a few months, at a time when only partial plans were known. Paper read before Assn. Iron & Steel Elec. Engrs.

The Hog Island of Today. Pac. Mar. Rev., vol. 16, no. 5, May 1919, pp. 83-94, 21 figs. and supp. chart. Technical data of engineering features connected with design and construction of ships being built and construction and management of yard.

Welding

Some Experiences with Electric Welding in Warships, W. H. Gard. Shipbuilding & Shipping Rec., vol. 13, no. 16, Apr. 17, 1919, pp. 485-486. Repairing cast-steel stern post of battleship and similar work carried out during the war. Paper read before Instn. Naval Architects.

Electric Welding in Ship Construction. Elec. Eng., vol. 52, no. 5, Nov. 1918, pp. 14-15. Projects and some experimental results obtained by British Admiralty.

Electric Welding, Thomas T. Heaton. Steamship, vol. 30, no. 359, May 1919, pp. 252-253. Systems applied to welding of mild steel. Paper read before Instn. Mech. Engrs.

Industrial Technology

Ammonia Oxidation

The Oxidation of Ammonia, W. S. Landis. Chem. & Metallurgical Eng., vol. 20, no. 9, May 1, 1919, pp. 476-477, 5 figs. Review of early investigations beginning in 1839 with Kuhlman; Ostwald process and apparatus; improvements made in catalyst screens platinum activation to foreign gases such as acetylene and phosphine; cyanamide process at Muscle Shoals. Paper read before Am. Electrochemical Soc.

Boron

The Production of Amorphous Boron (Ueber die Darstellung des amorphen Bors), Wilhelm Kroll. Zeitschrift für anorganische & allgemeine Chemie, vol. 102, no. 1, Jan. 4, 1918, pp. 1-33, 4 figs. Writer describes experiments made and results obtained by reduction with aluminum, magnesium, calcium, natrium, and by electrolysis. Apparatus for quick distillation of boric acid with methylene alcohol is described.

Cements, Rubber

Notes on Cemented Seams and Rubber Cements, Junius David Edwards and Irwin L. Moore. India-Rubber Jl., vol. 57, no. 15, Apr. 12, 1919, pp. 1-6, 8 figs. Tests and examination of micro-sections. It is concluded that a good seam requires a good cement, smoothing and cleaning of surface.

Dust Elimination

Removal of Dust, Gases and Fumes in Metal-Working Plants, J. J. Rosedale. Metal Trades, vol. 10, no. 5, May 1919, pp. 223-226, 6 figs. Recommended specifications for design, construction and operation of exhaust systems. From Cal. Safety News.

Electrical Precipitation of Solids from Flue Gases, J. M. Wauchope. Elec. Rev., vol. 74, no. 19, May 10, 1919, pp. 744-747, 7 figs. Application of Cottrell process to waste gases of smelters. Article dwells particularly on apparatus used, operating conditions, and troubles.

Explosives

Modern Explosives, J. Young. Jl. & Trans. Soc. Engrs., vol. 10, no. 3, 1919, pp. 109-130. Historical sketch of development during last 50 years leads writer to assert that no epoch-making discovery has been made during this time, but he examines the work which has been accomplished in inventing mixtures of old materials and grading them in order to make them suitable for various purposes.

Fertilizers

Sodammonium Sulphate. A New Fertiliser. The Utilisation of Nitre Cake in the Fixation of Ammonia, H. M. Dawson. Jl. Soc. Chem. Indus., vol. 38, no. 8, Apr. 30, 1919, Trans. pp. 98T-101T, 1 fig. Diagram illustrating crystallization of solutions containing sodium and ammonium sulphate.

Gas Masks

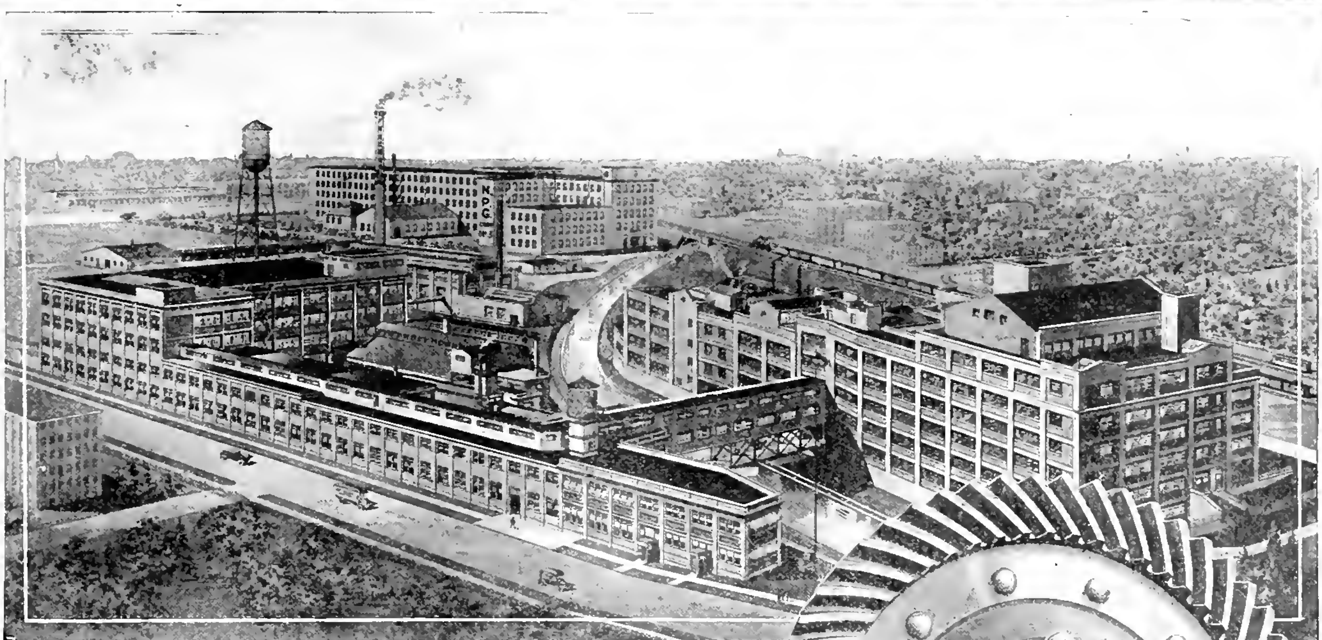
Effect of Exposure to Weather on Rubber Gas Mask Fabrics, G. St. J. Perrot and A. E. Plumb. Jl. Indus. & Eng. Chem., vol. 11, no. 5, May 1919, pp. 438-443, 6 figs. Investigation by Research Division, Chem. Warfare Service.

Gas Mask Absorbents, Arthur B. Lamb, Robert E. Wilson and N. K. Chaney. Jl. Indus. & Eng. Chem., vol. 11, no. 5, May 1919, pp. 420-438, 10 figs. Reasons underlying choice of mixtures used by Chemical Warfare Service. Mixture used in canisters contained 60 per cent 6 to 14 mesh coconut-shell charcoal and 40 per cent 8 to 14 mesh soda-lime-permanganate granites. Other combination selected was 75 per cent specially impregnated coconut charcoal and 25 per cent of soda-lime containing no permanganate.

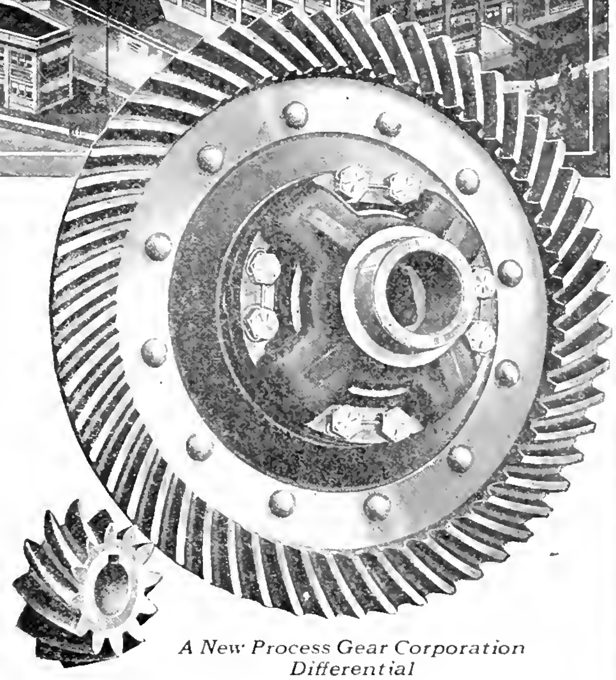
Nitrogen Fixation

The Present Status of Nitrogen Fixation, Alfred H. White. Sci. Am. Supp., vol. 87, no. 2264, May 24, 1919, pp. 330-331, 1 fig. Several processes contrasted on basis of recent experience. Address delivered at meeting of Am. Inst. of Chem. Engrs.

How the Nitrogen Problem Has Been Solved—III, Henry Jermain Maude Creighton. Jl. Franklin Inst., vol. 187, no. 5, May 1919, pp. 599-610, 2 figs. Outline of principles underlying formation of calcium cyanide from calcium carbide and atmospheric nitrogen. (To be concluded.)



The Ten-Acre Plant of the New Process Gear Corporation



A New Process Gear Corporation Differential

Six Acres of Manufacturing Space

in these buildings are devoted to the manufacture of *differentials* and *gears.*

Hearty co-operation of the gear specialists with the best of modern equipment combine to produce gears of quality.

New Process Gear Corporation
Syracuse New York

New Process Gears

Paints

The White Pigments, S. J. Cook. Can. Chem. Jl., vol. 3, no. 5, May 1919, pp. 145-147. Survey of present practice and magnitude of these paint industries. Address delivered before Ottawa Branch, Soc. Chem. Indus.

Salt

The Salt Industry and the Possibilities for the Future Development in Canada, L. Heber Cole. Can. Min. Jl., vol. 40, no. 19, May 14, 1919, pp. 346-366, 1 fig. Flow sheet indicating method employed in recovery of commercial salt from nature; deposits of British Columbian, Albertan, Manitoban, Ontario and Maritime provinces.

Seaweed Products

Industrial Uses of Seaweed (Sjotang som raastof for Sorindustri). Teknisk Ukeblad, vol. 66, no. 12, Mar. 21, 1919, pp. 172-174, 4 figs. "Norgin" manufactured from seaweed is used as dressing for cotton and linen fabrics and by painters for the preparation of inside walls and ceilings.

Soda Ash

Huge Industrial Development by Brunner Mond Co. at Amherstburg, Ont. Contract Rec., vol. 33, no. 18, Apr. 30, 1919, pp. 403-406, 5 figs. Process to be employed in manufacture of soda ash utilizes as two of principal raw materials limestone and salt.

Thallium

Note on Extraction of Thallium from Pyrites Flue Dust, George Sisson and J. S. Edmondson. Chem. News, vol. 118, no. 3078, Apr. 11, 1919, p. 75. Method depends upon solubility of chloride and sulphate, operation being to treat the dust with boiling water acidified with sulphuric acid.

Wood Pulp

The Chemistry of Wood Pulp Production. Arthur Klein. Paper, vol. 24, no. 10, May 14, 1919, pp. 15-19. Theories concerning constitution of cellulose. Paper read before German Assn. of Cellulose and Paper Chemists. (To be continued.)

Railroad Engineering

FOREIGN

European Train Speeds

European Train Speeds. Ry. Gaz., vol. 30, no. 16, Apr. 18, 1919, pp. 685-687, 2 figs. Survey of highest, longest and fastest non-stop runs, speed of trains between two places and geographical distribution of important services. Balkan States, Roumania, Germany. (Continuation of serial.)

Foreign Developments

Railway Developments in Foreign Countries. Ry. Age, vol. 66, no. 19, May 9, 1919, pp. 1163-1164. Proposed extension in Peru; suggestions for trading with Greece; South African news.

Norway

Transport Conditions on Norwegian Railways During the War (Vore jaernbaners transport forhold under Krigen), Chr. Platou. Teknisk Ukeblad, vol. 66, vo. 11, Mar. 14, 1919, pp. 147-156, 15 figs. Development and present conditions. Railways are state-owned. Figures indicating traffic during the war.

CONSTRUCTION

Welding Outfits

Local Building of Railway Special Work with the Aid of an Oxygen-Acetylene Cutting and Welding Outfit, Montelle C. Smith. Stone & Webster Jl., vol. 24, no. 5, May 1919, pp. 402-409, 4 figs. Experience in building frogs, switchmates and switches.

ELECTRIC RAILROADS

Battery Locomotives

Electric Battery Locomotives. Quarry, vol. 24, no. 267, May 1919, pp. 125-126, 1 fig. Consideration given to Brush type by Ministry of Munitions. These locomotives haul loads of three to four tons on level track.

Locomotive Design

The Progress of Electric Locomotive Design, W. B. Potter and S. T. Dodd. Ry. Age, vol. 66, no. 19, May 9, 1919, pp. 1157-1158. States that geared motors mounted directly on the axle will probably be continued for freight and slow-speed passenger work, while locomotives for high-speed passenger service will be preferably of gearless design.

Regenerative Braking

The Economics of Electric Operation of Railways, W. G. Gordon. Jl. Eng. Inst. Can., vol. 2, no. 5, May 1919, pp. 398-401. Costs of maintenance of electric locomotive for an average of five years for three railroads, an average of four years for two roads, an average of 2 years for C., M. & St. P. RR., with figures of saving effected by regenerative braking obtained by this road.

Substations, Railway Converter

Railway Converter Substations, C. E. Lloyd. Elec. Eng., vol. 53, no. 3, Mar. 1919, pp. 108-112, 3 figs. Plan of Taggart Street substation, Pittsburgh Railways Co.

Westinghouse Pneumatic Controller

Westinghouse Pneumatic Controller of French Suburban Locomotives (Equipment Westinghouse pour la commande électro-pneumatique des automotrices de banliene des chemins de fer de l'Etat), Lucien Pahin. Industrie Electrique, vol. 28, no. 644, Apr. 25, 1919, pp. 145-148, 1 fig. Scheme of connections and description of operation. (Concluded.)

ELECTRIFICATION

Electrification and Policies

Some Possibilities of Steam Railroad Electrification as Affecting Future Policies, Calvert Townley. RR Herald, vol. 23, no. 6, May 1919, pp. 133-135. Fundamental difference between electrification and steam propulsion. Emphasizes, among other features, practically unlimited power electricity can furnish as compared to strictly limited motive power of locomotives.

France

Partial Electrification of French Railways; Experiences Acquired in France and in Other Countries Concerning Electrification of Main-Line Roads (Programme d'électrification partielle des chemins de fer français; expérience actuellement acquise en France et à l'étranger dans l'électrification des grandes lignes), A. Mauduit. Bulletin de la Société Française des Electriciens, vol. 9, no. 78, Mar. 1919, pp. 127-160, 8 figs. Figures indicating fuel economy; types of locomotives, particularly three-phase designs used in Simplon tunnel; operating practice.

Iowa

Electrification of Steam Road Results in Service and Success. Elec. Traction, vol. 15, no. 5, May 1919, pp. 290-293, 9 figs. Iowa Southern Utilities Co.'s experience.

Limiting Factors

Main Line Railway Electrification. Times Eng. Supp., vol. 15, no. 534, Apr. 1919, p. 127. Some limiting factors.

Locomotive Characteristics

Railroad Electrification, F. H. Shepard. Jl. Eng. Inst. Can., vol. 2, no. 5, May 1919, pp. 402-406 and (discussion) pp. 406-409, 10 figs. Examples of track arrangement and details of locomotive design. Graphs indicating comparative steam- and electric-locomotive characteristics.

Pantagraph Shoe Design

Railroad Electrification Facts and Factors, A. J. Manson. Ry. Elec. Engr., vol. 10, no. 5, May 1919, pp. 147-149, 4 figs. Pantagraph shoe design is governed by class of service in which the locomotive operates.

Progress

Steam Railroad Electrification, Calvert Townley. Elec. Eng., vol. 53, no. 4, Apr. 1919, pp. 170-172. Blames electrical men for slow progress during last 20 years.

Swiss Railways

Electrification of Swiss Railways (Die Elektrifizierung der Schweiz. Bundesbahnen), E. Huber-Stockar. Schweizerische Bauzeitung, vol. 73, no. 15, Apr. 12, 1919, pp. 174-178, 4 figs. Difficulties encountered concerning supply of labor and material. Idea of electrification was suggested and work hastened by steadily increasing shortage of coal. Description of various power stations and single-phase a. c. 15,000 60,000-volt transformer for Riton power station. (To be concluded.) Paper read before Zürcher Ingenieur & Architekten Verein.

LOCOMOTIVES

Comparative Efficiencies, Compound and Simple Locomotives

Comparative Efficiency of a Compound and a Simple Locomotive Both Using Superheated Steam, C. J. Mellin. Loco, vol. 10, no. 1, May 1919, pp. 3-11, 4 figs. Diagrams worked out from investigation as to ranges in temperatures and expansion of superheated steam.

Electric Locomotives

See Electric Railroads.

Feedwater Heaters

Feed Water Heaters and Their Development, J. Snowden Bell. RR. Herald, vol. 23, no. 6, May 1919, pp. 143-148, 5 figs. Forms of feedwater heaters being applied in the U. S. A. by various locomotive works. (Continuation of serial.)

Pulverized Coal

Utilization of Pulverized Coal in Locomotives (L'emploi du charbon pulvérisé sur les locomotives), E. Lasseur. Génie Civil, vol. 74, no. 18, May 3, 1919, pp. 345-349, 7 figs. Present development of this application, notably as practiced by the Locomotive Pulverized Fuel Co., N. Y.

Pulverised Fuel Locomotive. Engineer, vol. 127, no. 330A, Apr. 25, 1919, pp. 400-402, 8 figs. on supp. plate. In order to make fire-box suitable for use of pulverized fuel, grate and ashpan were removed and two openings, each $7\frac{1}{2}$ in. in diameter, were made through the water space; through these openings pulverized fuel with a certain proportion of air is injected. Apparatus located on tender and steam-driven throughout.

Standard Locomotives

Standard 4-6-2 Type Locomotives. Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 230-235, 14 figs. Locomotive is somewhat similar in its proportions to M., K. & T. locomotive, which, however, has more heating surface, but a considerably smaller grate and a smaller ratio of firebox heating surface to total heating surface.

The Administration Standard Light Mountain Type. Ry. Age, vol. 66, no. 20, May 16, 1919, pp. 1193-1196, 5 figs. Weight 327,000 lb., tractive effort 53,900 lb. with factor of adhesion of 4.2.

Swiss Locomotives

Brown-Boveri Locomotives for the Swiss Federal Railways, J. Buchli. Engineering, vol. 107, no. 2783, May 2, 1919, pp. 562-565, 12 figs., partly on supp. plate. Spur gearing and coupling rods transmit power from motor to driving axles. (To be continued.)

Tank Engines

2-6-4 Tank Engine, Class K, South Eastern and Chatham Railway. Ry. Engr., vol. 40, no. 472, May 1919, pp. 102-103, 2 figs. Design drawings with dimensions.

Tests

Locomotive Performance—IV, E. G. Young. Loco, vol. 10, no. 1, May 1919, pp. 12-17, 4 figs. Curves obtained in tests made on a Pacific-type locomotive at Pennsylvania laboratory, Altoona.

Uniflow

New Express Locomotive with "Uniflow" Cylinders, North Eastern Railway. Ry Gaz., vol. 30, no. 19, Ma .., 1919, pp. 801-803, 5 figs. Boiler has length of 15 ft. $10\frac{1}{2}$ in. and diameter of 5 ft. 6 in.; cylinders, $16\frac{3}{4}$ in. diameter by 26 in. stroke.

MAINTENANCE

Car Trucks

Problems in Design and Maintenance of Car Trucks in Relation to Maintenance of Roadway, W. J. Hyman. Official Proc. Can. Ry. Club, vol. 18, no. 4, Apr. 1919, pp. 15-22 and (discussion) pp. 23-35, 3 figs. Wheel-base trucks in relation to tracks and flat spots from viewpoint of Car Department.

Progress

Progress in Railroad Engineering and Maintenance, as Developed in the Annual Convention of the American Railway Engineering Association, Chicago, March, 1919, J. C. Irwin. New England RR. Club, Apr. 8, 1919, pp. 65-104. Following subjects are touched upon: Flat spots on wheels; economics of railway labor; war emergency yard improvements; umbrella vs. butterfly sheds; screw spikes.

PATENTED

BIGNESS

Bunting Bushing Service is typically American—Big production, highly intensified.

Someone says we have the largest factory in the world devoted to Bushings exclusively—anyway we're BIG.

Specialized, exceptionally accurate, high speed machinery brings LOW PRICES and " INSTANT " SERVICE.

Long experience and an intense faith in the commercial value of a good article keeps Bunting Bushings a QUALITY PRODUCT.

Get Our Figures

Plain Bronze Bushings and Babbitted Bearings —pattern and tool equipment for over 10,000 standard designs or " specials " as ordered. 107 compositions on file—alloys compounded with absolute accuracy.

THE BUNTING BRASS AND BRONZE CO.

729 Spencer Street **TOLEDO, OHIO**

OPERATION AND MANAGEMENT

Accident Prevention

The Prevention of Accidents at Railroad Grade Crossings. Proc. Pac. Ry. Club, vol. 2, no. 12, Mar. 1919, pp. 12-22. Present methods for preventing accidents were discussed as practiced in various parts of the country by different members of the club.

Fuel Conservation

Reduction of Fuel Consumption on the Northern Pacific Railroad, M. A. Daly. Official Proc., N. Y. R. R. Club, vol. 29, no. 6, Apr. 18, 1919, pp. 5632-5636, also Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 237-240, 21 figs. Fuel-instruction car employs laboratory demonstrations and moving pictures.

Oil-Fuel Trials

Oil Fuel Trials; North Western State Railway, India. Ry. Engr., vol. 40, no. 472, May 1919, pp. 90-92, 4 figs. Report of trials which have been in progress since 1913. Result is said to be that locomotives are to be fitted to burn 60,000 tons of oil per annum. Technical paper no. 193, Gov. Printing Dept., Calcutta.

PERMANENT WAY AND BUILDINGS

Abutments

Reinforced Concrete Framed Railway Abutments, Albert M. Wolf. Eng. World, vol. 14, no. 9, May 1, 1919, pp. 23-24, 3 figs. C., M. & St. P. R. R. abutments carry tracks over ends of high embankments, and instead of retaining the embankment, allow it to slope out between and around the abutment posts or piers.

Grade Crossings

Engineering Treatment of Necessary Railroad Grade Crossings, Rodman Wiley. Mun. & County Eng., vol. 56, no. 5, May 1919, pp. 191-193, 1 fig. Recommends that important crossing be well paved, paving to be level with top of rails, so as to prevent man killing his engine on track.

General Aspects of Grade Separation. Contract Rec., vol. 33, no. 19, May 7, 1919, pp. 440-443. Report issued by Division of Grade Separation and Bridges of city of Detroit. Question is viewed in its relation to city planning and cost of elevating railroads.

RAILS

Weight of Rail and Axle Load

Relation of Weight of Rail to Axle-Load, G. Richards. Ry. Gaz., vol. 30, no. 17, Apr. 25, 1919, pp. 715-716. Reasons for scales of axle loads prescribed in "Schedules of Maximum, Minimum and Recommended Dimensions to be observed on all 5-ft. 6-in., 2-ft. 6-in. and 1-metre gauge railways in India," for 1913 and limitations for spacing of sleepers. From Roy. Engrs. Jl.

ROLLING STOCK

Draft Gear

Freight Car Draft Gear Test Demonstrations. Ry. Age, vol. 66, no. 18, May 2, 1919, pp. 1097-1100, 6 figs, also Ry. Mech. Engr., vol. 93, no. 5, May 1919, pp. 249-252, 6 figs. Method of recording action under impact between cars devised by Inspection and Test Section of Division of Operation, U. S. R. R. Administration.

Perishable-Food Cars

On the Design of Railway Wagons for the Carriage of Perishable Foods. Dept. Sci. & Indus. Research, Food Investigation Board, special report no. 1, 1919, 8 pp. Among other suggestions it is advised that doors be laid in two portions, being divided horizontally.

Refrigerator Cars

Report on English Refrigerator Cars. Cold Storage & Produce Rev., vol. 22, no. 253, Apr. 17, 1919, pp. 87-90. Document from Government Research Sub-Committee. Urges, among other things, that special attention be directed to airtightness, especially as regards fitting of doors.

SAFETY AND SIGNALING SYSTEMS

Block-Signaling Practice

Block Signaling Practice on a British Railway. F. B. Holt and A. B. Wallis. Ry. Signal Engr., vol. 12, no. 5, May 1919, pp. 159-161, 3 figs. Electrical equipment used in signal tower on the Midland. First of series of three articles.

Low Frequency System

Supply and Transmission for Modern Railway Signalling, A. E. Tattersall. Ry. Engr., vol. 40, no. 472, May 1919, pp. 92-95, 2 figs. Advantages of low frequency are claimed to be possibility of using standard d. c. apparatus, economy in installation, improvement of power factor and greater variation in operating values of apparatus.

Reinforced-Concrete Appliances

Reinforced Concrete for Signal Work in England, A. C. Rose. Ry. Signal Engr., vol. 12, no. 5, May 1919, pp. 152-154, 6 figs. Types of reinforced-concrete signal and telegraph poles, stakes and other appliances.

SHOPS

Dipping and Baking

Insuring Electrical Equipment by Efficient Dipping and Baking, W. G. Lamb. Elec. Traction, vol. 15, no. 5, May 1919, pp. 307-309, 5 figs. Experience with dipping and baking process of Waterloo, Cedar Falls & Northern Railway.

Halifax Car Repair Shops

Car Repair Building for C. N. R. at Halifax, J. J. MacDonald. Contract Rec., vol. 33, no. 19, May 7, 1919, pp. 427-429, 5 figs. Shell of building consists of plain concrete base wall rising to level of window sills, a series of narrow wall piers between windows and reinforced-concrete entablature and parapet wall above window openings.

Omaha Car Barns

New and Modern Car Barn in Omaha. Elec. Traction, vol. 15, no. 5, May 1919, pp. 293-296, 5 figs. Structure of 100 cars capacity, including feature of single line of columns, giving maximum unobstructed floor space.

Roundhouse Design

Some Modern Tendencies in Roundhouse Design, Exum M. Haas. Ry. Age, vol. 66, no. 20, May 16, 1919, pp. 1199-1201. Economy in permanent construction. Paper read before Western Soc. of Engrs.

Welding

Welding Locomotive Drive Wheel. Welding Engr., vol. 4, no. 5, May 1919, p. 29, 2 figs. Pin was broken off flush with wheel; job was performed without removing wheel or preheating.

SPECIAL LINES

Narrow-Gage Repair Shop Trains

Repair Shop Train Used on Narrow Gage in Flanders, F. C. Coleman. Ry. Age, vol. 66, no. 19, May 9, 1919, pp. 1139-1140, 3 figs. Portable machine shop equipped with electric-motor-driven tools and gasoline generator sets.

See also MINING ENGINEERING, Transportation.

STREET RAILWAYS

New Orleans

Suggested Changes in the Operation of the Street Railway System of New Orleans, W. T. Hogg. Proc. Louisiana Eng. Soc., vol. 5, no. 1, Feb. 1919, pp. 25-78, 22 figs. Analysis of present routes from viewpoint of principles said to be scientifically based on geographic relations of commercial, industrial, residential and recreative centers. Present system found inadequate and modifications suggested.

New York

Six Years of Rapid-Transit Progress in New York, D. L. Turner. Eng. News-Rec., vol. 82, no. 18, May 1, 1919, pp. 865-869, 8 figs. Graphs showing cost of labor, comparison and work accomplished on old and new subway lines.

Rehabilitation Track Standards

Chicago Rehabilitation Track Standards Prove Successful. Elec. Ry. Jl., vol. 53, no. 18, May 3, 1919, pp. 865-869, 5 figs. Five standard types adopted in 1907 and 1909. Study made of rail corrugation as influenced by several types of construction.

Wheels and Axles

Steel-Tired Wheels and Axles, H. Vernon. Elec. Ry. Jl., vol. 53, no. 20, May 17, 1919, pp. 961-963, 7 figs. Practice at tramway sheds of Belfast, Ireland.

TERMINALS

Coaling Station, Lehigh Valley RR.

Modern Railroad Coaling Station, M. V. Bailliere. Coal Trade Jl., vol. 50, no. 19, May 17, 1919, pp. 519-520, 2 figs. Facilities provided for coaling on six different tracks in station built for Lehigh Valley R. R. at Manchester, N. Y.

D. & R. G. Freight Terminal

Novel Features in New D. & R. G. Freight Terminal. Ry. Age, vol. 66, no. 18, May 2, 1919, pp. 1083-1085, 7 figs. Facilities at Salt Lake City include two freight houses, transfer platforms and a team yard.

N. Y. C. Engine Terminal

New York Central R. R. Engine Terminal, Gardenville, N. Y. Ry. Rev., vol. 64, no. 19, May 10, 1919, pp. 677-681, 10 figs. Engine house is equipped with boiler-washing and filling apparatus, portable electric-welding equipment, hoists and trolleys for handling heavy locomotive parts, etc.

Munitions and Military Engineering

Airdromes

American Combat Airdromes, Charles C Loring. Architectural Rec., vol. 45, no. 4, Apr. 1919, pp. 311-324, 18 figs. Plans show characteristic irregular grouping necessary to render plants less vulnerable as targets.

Ammunition, Artillery

The Design of Artillery Ammunition and Some Recent Developments at Frankford Arsenal, J. Wallace Taylor. Jl. Engrs. Club Philadelphia, vol. 36-4, no. 173, Apr. 1919, pp. 127-137, 8 figs. Pressure-velocity curves of a medium-caliber gun; graphs showing travel of projectile against twist torque; table indicating atmospheric resistance to flight of projectile with ogival head of 2-caliber radius.

Artillery, Railway

Railway Artillery, E. D. Campbell. Jl. Engrs. Club of St. Louis, vol. 4, no. 2, Mar.-Apr. 1919, pp. 142-160, 9 figs. Historical sketch and forecast of future types.

Railway Mounted Artillery in the War. Ry. Age, vol. 66, no. 20, May 16, 1919, pp. 1205-1209. Development of mobile guns from 1863 to time of armistice with special reference to American types.

Automobile Service, French

French Military Automobile Service (Le service automobile militaire française), Robert Altermann. Génie Civil, vol. 74, no. 15, Apr. 12, 1919, pp. 291-294, 3 figs. Account of its operation during the war.

Battle Cruisers

The Battle Cruiser, E. F. Eggert. U. S. Naval Inst. Proc., vol. 45, no. 5, May 1919, pp. 719-728. Suggests a type which is said to combine high speed of cruiser and fighting ability of battleship. It is to be 650 ft. long with 28 ft. draft, 20,000 tons displacement, 32 knots speed and have power of 100,000 i. hp.

Battleships

United States Battleship New Mexico, S. M. Robinson. Int. Mar. Eng., vol. 24, no. 5, May 1919, pp. 323-334, 26 figs. Description of propelling machinery; trial data.

Camouflage

A System of Camouflage for Railway Mounts, John M. Goodwin. Jl. U. S. Artillery, vol. 50, no. 3, May 1919, pp. 253-267, 14 figs. Two systems: (1) five-color system for concealment of heavy railway mounts in which great mass of solid surface must be broken up into several separate masses and shadow cast by mount must also be hidden; (2) three-color system which consists principally in an endeavor to hide field piece by blending its form and shadow with landscape, this being accomplished by use of green, yellow and cream.

Camps

The Army's Utilization of Camp Wastes, F. C. Bamman. Mun. Jl. & Public Works, vol. 46, no. 17, Apr. 26, 1919, pp. 304-308, 2 figs. Results of changing from incineration to utilization. (To be concluded.)

Camp Wastes

The Army's Utilization of Camp Wastes, F. C. Bamman. Mun. Jl. & Public Works, vol. 46, no. 18, May 3, 1919, pp. 322-325. Form of contract said to secure great economy in use of food, more material from which glycerine can be derived, and larger revenue.

Engineering, Italian

Notes on the Operations of the Italian Engineers, James H. England. Prof. Memoirs, Corps Engrs., U. S. Army & Engr. Dept., vol. 11, no. 5, Jan.-Feb. 1919, pp. 128-133, 5 figs.

Deals with waterways and roads, the latter being designed and constructed with a view to accommodating 10-ton power trucks.

Fortifications

The Future of Permanent Fortifications, C. Beard. Prof. Memoirs, Corps of Engrs., U. S. Army & Engr. Dept., vol. 11, no. 55, Jan.-Feb., 1919, pp. 47-64. Author holds that by paying the price it will be possible in the future to construct fortifications capable of withstanding projectiles of large caliber, but remarks, quoting Napoleon, that "like cannon, fortresses are arms which alone cannot fulfill their missions."

Gas Masks

Gas Defense, Oscar E. Stevens. Stone & Webster Jl., vol. 24, no. 5, May 1919, pp. 365-371, 7 figs. Types of gas masks used by various belligerents during war.

Gun Emplacements

Notes on the Field Emplacement of a German Large Caliber Gun, G. P. Pillsbury. Professional Memoirs, Corp Engrs., U. S. Army & Engr. Dept., vol. 10, no. 54, Nov.-Dec., 1918, pp. 846-853, 3 figs. Foundation was wholly of structural steel and forged plates, no concrete being used. It had been prepared by excavating pit of required horizontal dimensions, about 7 ft. deep. No signs of overstrain were found in any part of foundation structure.

Gun Mounts

Making Naval Gun Mounts—III, Franklin D. Jones. Machy. (N. Y.), vol. 25, no. 8, Apr. 1919, pp. 745-749, 14 figs. Fixtures for broaching, milling and drilling operations, and testing methods. (Concluded.)

Gun, Photographic

The Photographic Gun, Edgar H. Felix. Aerial Age, vol. 9, no. 4, Apr. 7, 1919, pp. 198-199, 13 figs. Mechanism of gun camera showing Geneva movement and shutter mechanism, which automatically continues to take photos as long as trigger is depressed.

Gun Sights

Making Gun Sights for Anti-Aircraft Guns, Fred H. Colvin. Am. Mach., vol. 50, no. 15, Apr. 10, 1919, pp. 681-684, 10 figs. Mechanism consists primarily of a yoke attached to the recoil cyclinder which allows sight to be swung up and down on gun by means of curved rack governed by worm-actuated pinion in a case.

Guns

Making the U. S. 75-Millimeter Field Gun—II Erik Oberg. Machy. (N.Y.), vol. 25, no. 8, Apr. 1919, pp. 716-721, 27 figs. Methods developed by Wisconsin Gun Co., Milwaukee, Wis.

America's Great Effort in Ordnance—II. Sci. Am., vol. 120, no. 17, Apr. 26, 1919, pp. 432-433 and 444 and 446, 9 figs. Features of proving ground for testing army ordnance at Aberdeen, Md.

Guns, Location of

Listening for the Enemy. Sci. Am., vol. 120, no. 20, May 17, 1919, pp. 510-511, 8 figs. How a gun is located by timing its report as heard at three points.

Mine Protection

The Protection of Ships Against Mines II. Engineer, vol. 127, no. 3300, Mar. 28, 1919, pp. 293-294, 5 figs. Arrangements for towing projector-type paravanes on war ships and mercantile vessels.

Mining

The Work of the Miner on the Western Front, 1915-1918, H. Standish Ball. Bul. Instn. Min. & Metallurgy, no. 175, Apr. 1919, pp. 1-53, 32 figs., partly on 19 separate plates. Empirical formulæ by means of which fairly accurate calculations are said to have been made of the size and depth of the crater resulting from an explosion.

Mining in Chalk on the Western Front with Some Notes on the Explosion of Large Charges of High Explosives, L. B. Reynolds. Can. Min. Inst. Bul. no. 85, May 1919, pp. 483-493, 1 fig. Diagrammatic illustration of manner in which enemy works were located.

Motor-Transport Salvage Park

M. T. C. Salvage Park in France—I & II W. F. Bradley. Automotive Industries, vol. 40, nos. 16 & 17, Apr. 17 and 24, 1919, pp. 860-863 and 902-905, 19 figs. Reconstruction plant erected by Motor Transport Corps of U. S. army 120 miles behind front.

Munitions, Canada

Canada Made a Remarkable Record in Production of Munitions. T. M. Fraser. Can. [illegible], vol. 20, no. 26, Dec. 26, 1918, pp. 717-721. Imperial Munitions Board gives figures of total production in various plants.

Projectors

Projectors—British and German, Byron C. Goss. Nat. Service & Internat. Military Digest, vol. 5, no. 5, May 1919, pp. 276-280, 4 figs. Features of design and construction.

Railroad Transportation

Modern Armies and Modern Transport. Ry. Gaz., vol. 30, no. 14, Apr. 4, 1919, pp. 601-602. Work of North-Eastern Railway Co. during the war.

Roads

Military Roads as Constructed and Projected by the Construction Division, War Department, U. S. A., in 1918, Daniel B. Goodsell. Mun. & County Eng., vol. 56, no. 4, Apr. 1919, pp. 140-142, 10 figs. Typical cross-sections of cement concrete and bituminous pavements.

Submarine Detectors

The Wonderful Submarine Detector, Brewster S. Beach. Am. Mar. Engr., vol. 14, no. 4, Apr. 1919, pp. 8-14. Effort made by American scientists to perfect instrument for locating submarines while in a submerged condition.

Listening Devices in U-Boat War. Telephony, vol. 76, no. 15, Apr. 12, 1919, pp. 23 and 26-27. Development of submarine detecter by research laboratory experts of General Electric Co.

Stokes Gun

The Stokes Gun and Shell and Their Development, Wilfred Stokes. Professional Memoirs, Corps Engrs., U. S. Army & Engrs. Dept., vol. 10, no. 54, Nov.-Dec., 1918, pp. 765-788, 24 figs. Setting-up mechanism modified by introducing leg of heavier design and with only half the traverse. Similar improvements made in mechanism and accessories.

Supply Bases

Yard Tracks for Brooklyn Army Supply Base. Ry. Rev., vol. 64, no. 17, Apr. 26, 1919, pp. 609-611, 1 fig. Terminal arrangements and water-front development.

See also CIVIL ENGINEERING, *Bridges (Military), Building and Construction (Army Construction.)*

General Science

CHEMISTRY

Adsorption

Adsorption of Precipitates, Harry B. Weiser and J. L. Sherrick. Jl. Physical Chemistry, vol. 23, no. 4, Apr. 1919, pp. 205-252, 2 figs. Adsorption of following anions by precipitated barium sulphate said to have been determined: Chloride, bromide, iodide, chlorate, permanganate, nitrate, nitrite, cyanide, sulphocyanate, ferrocyanide and ferricyanide. Order of adsorption was not in accord with Schulze's law.

Analysis, Coke

Precautions Necessary in Grinding Samples of Coke for Analysis, A. E. Findley. Jl. Soc. Chem. Indus., vol. 38, no. 7, Apr. 15, 1919, pp. 93T-94T. Reports that samples of coke ground in an iron mill were found to be magnetic; consequently recommends placing coke in strong linen bag and grinding it to fine powder in agate mortar.

Analysis, Gas

An apparatus for the Automatic Estimation of Small Amounts of Oxygen in Combustible Gas Mixtures or of Combustible Gases in Air, H. C. Greenwood and A. T. S. Zealley. Jl. Soc. Chem. Indus., vol. 38, no. 7, Apr. 15, 1919, pp. 87T-90T, 3 figs. Principle involved is that of combustion of oxygen or impurity by means of intermittently heated platinum wire.

The Determination of Sulphites, and of Sulphur Dioxide in Gaseous Mixtures, Percy Heller. Jl. Soc. Chem. Indus., vol. 38, no. 5, Mar. 15, 1919, pp. 52T-56T. It is concluded from experimental research that the addition of 5 per cent glycerin to solutions or sulphites, or to caustic soda solutions used in absorbing sulphur dioxide, prevents any loss by spontaneous oxidation to sulphate.

Analysis, Phosphorus

The Estimation of Phorphorus in the Presence of Tungsten, G. Watson Gray and James Smith. Iron & Steel Inst., Ann. Meeting, May 8 & 9, 1919, no. 5, 4 pp. Method devised by writers.

Analysis, Steel

Determination of Uranium, Zirconium, Chromium, Vanadium and Aluminium in Steel—I, Charles Morris Johnson. Chem. & Metallurgical Eng., vol. 20, no. 10, May 15, 1919, pp. 523-524, 1 fig. Method based on fact that when ammonia is added to iron in the ferrous state the unoxidized iron is first converted to double sulphate of ferrous iron and ammonium and remains in solution. Addition of ammonia forms precipitate.

Colloids

The Colors of Colloids—III & IV, Wilder D. Bancroft. Jl. Physical Chemistry, vol. 23, nos. 3 & 4, Mar. & Apr. 1919, pp. 154-185 and 253-282. Rayleigh's discussion of visibility of polished surfaces; phenomena exhibiting invisibility due to uniform illumination; soap bubbles, oil or tar upon water, tempered steel, the brilliant colors of lead skimmings, Nobili's metallochrome, insects' wings, and other objects exhibiting colors of thin plates. Survey and analysis of various theories.

Rubber

Rubber as a Colloid, D. F. Twiss. Jl. Soc. Chem. Indus., vol. 38, no. 5, Mar. 15, 1919, pp. 47T-49T and (discussion) pp. 49T-50T. Suspensoid character of rubber is deduced from its behavior in electrolytic process of separating it from latex.

Solubility

Theory of Solubility (Théorie de la solubilité), Albert Colson. Comptes rendus des séances de l'Academie des Sciences, vol. 168, no. 13, Mar. 31, 1919, pp. 681-684. Thermodynamic interpretation of sense of phenomenon, eutectic concentrations, angular points, etc. A formula of solubility is developed from the chemical principle established by Chesneau that the concentration of a solution varies in the same sense as the osmotic pressure.

Solutions

Sulphur as a Cryoscopic Solvent (Schwefel als kryoskopisches Losungsmittel), E. Beckmann and C. Platzmann. Zeitschrift fur anorganische & allgemeine Chemie, vol. 102, no. 3, Apr. 9, 1918, pp. 201-214. Describes results of series of tests. Adjustment of "natural" melting point; determination of cryoscopic constant; catalytic influences; some applications of cryoscopic constant to anorganic substances.

On the Determination of Boiling Points of Solutions, F. G. Cottrell. Jl. Am. Chem. Soc., vol. 41, no. 5, May 1919, pp. 721-729, 1 fig. Particulars of method described consist in placing thermometed bulb in gas phase as in the case of a pure liquid and making the boiling of the liquid itself pump some of the latter mechanically in a thin film over it, thus duplicating as far as possible the same relations of gas, liquid and thermometer which ordinarily obtain in boiling-point determinations of pure substances.

Ultra-Violet Rays

Use of Ultra-Violet Rays—XXIV. Chem. Engr., vol. 27, no. 4, Apr. 1919, pp. 102 and 20 (adv.) Description of absorption spectra apparatus and ultra-violet light filters.

MATHEMATICS

Bessel-Clifford Function

The Bessel-Clifford Function, G. Greenhill. Engineering, vol. 107, no. 2776, Mar. 14, 1919, p. 334. Claims to simplify formula relating to stability, statistical and dynamical of a beam, strut or whirling shaft.

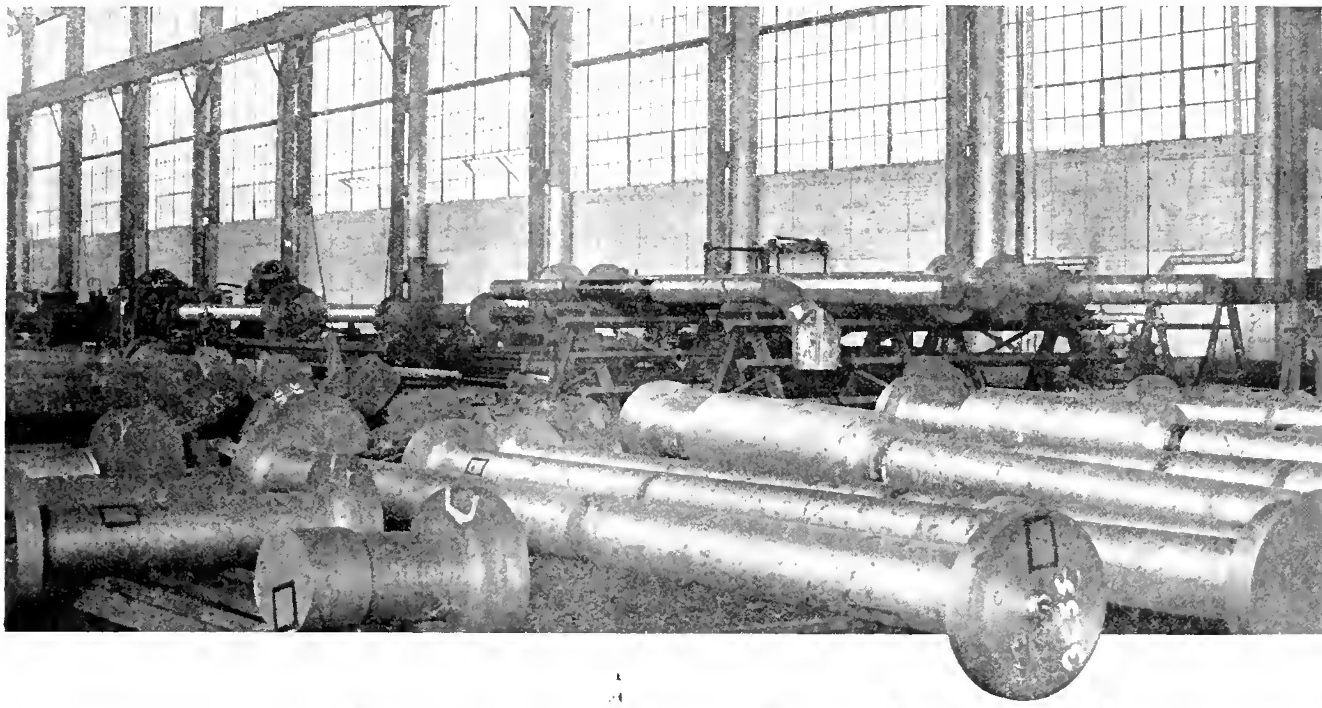
Equations

Linear Equations with Unsymmetric Systems of Coefficients, A. J. Pell. Trans. Am. Mathematical Soc., vol. 20, no. 1, Jan. 1919, pp. 23-29. Theory for linear equations in infinitely many unknowns. Method followed consists in reduction, by means of biorthogenal system, to system of linear equations with limited symmetric matrix of coefficients.

Solution of Simultaneous Linear Differential Equations and Certain Problems in Mechanics by means of D Symbol (Applications du calcul symbolique a l'integration des éguations différentielles linéaires simultanées et à la résolution de certains proldèmes de mécanique), H. Vogt. Revue Générale de l'Electricité, vol. 5, no. 16, Apr. 1919, pp. 581-589. In R. G. E., vol. 2, Sept. 29 and Oct. 13, 1917, pp. 483 and 563, writer applied this system of solution to single differential equations occurring in electrotechnics; in present note application is extended to simultaneous equations and exemplified in various cases of vibratory motion and gyroscopic action.

The General Solution of the Indeterminate Equation: $Ax + By + Cz + \ldots = r$, D. N. Lehmer. Proc. Nat. Acad. Sciences, vol. [illegible] no. 4, Apr. 1919, pp. 111-114. Treats equation in same non-tentative way that is found in continued fraction solution for two variables.

CAMDEN



DON'T STOP

to wonder whether we can make your forgings.

CAMDEN FORGINGS

are made for innumerable purposes.

We are interested in knowing of your forging requirements. We know that we can interest you in our plant and its product.

Let these considerations lead to our receipt of your forging inquiries.

BUYERS' MEMO

High and Low Carbon Bars
Press Columns and Rams
Pull Back Cylinders
Water Cylinders
Valve Bodies
Plungers
Weldless Steel Rings
Lathe Spindles, solid and hollow bored
Long Feed Screws
Power Press Crank Shafts
Rudder Arms

Rudder Stocks
Cam Shafts
Eccentric Shafts
Crusher Shafts
Gear and Pinion Blanks
Locomotives: Side and Main Rods; Crank Pins; Axles; Rod Straps; Guides; Parts of frame both in iron and steel

Hammered Iron Bars for locomotive repairs
Marine Shafts
Marine Connecting and Eccentric Rods
Rolls: Bending; Feed; Straighten'ng; *Embossing*
Large Wrenches
Saw Arbors

Steam Engine Forgings
Pump Crank Shafts
Pump Connecting Rods
Large Nuts
Turbine Shafts
Mill Shafting
Trolley Car Axles
Electric Motor Axles
Any forging to your print, and specifications, in either iron or steel

CAMDEN FORGE CO.
CAMDEN, N.J., U.S.A.

Functions

Approximation Polynomials and the Existence of Derivatives (Sur les polynomes d'approximation et l'existence des dérivées), Paul Montel. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 4, Jan. 27, 1919, pp. 215-217. Theorem establishing relation between differential properties of function to order of nearest approximation $u(n)$ of this function by polynomial of degree inferior or equal to n.

Fundamental Geometric Magnitudes

Fundamental Geometric Magnitudes of Euclidian Space (Les géométries fondamentales de l'espace euclidien), René de Saussure. Archives des Sciences Physiques et Naturelles, year 124, vol. 1, Jan.-Feb. 1919, pp. 29-47. Study of figures possible in one-dimensional space and of quanta of two and three paramaters. (To be continued.)

Implicit Functions

Implicit Functions (Sur les fonctions de lignes implicites), Paul Lévy. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 3, Jan. 20, 1919, pp. 149-152. Conditions under which inversion of point transformation is constant and uniform.

Integration

On the Analytical Extension of the Integrals of Certain Systems of Equations to the Linear Partial Derivatives (Sur le prolongement analytique des intégrales de certains systemes d'equations aux derivées partielles linéares), M. Riquier. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 3, Jan. 20, 1919, pp. 144-147. Considers as illustrative example case of five independent variables in seven arbitrary functions.

Isomorph

A Partial Isomorph of Trigonometry, E. T. Bell. Bul. Am. Mathematical Soc., vol. 25, no. 7, Apr. 1919, pp. 311-321. Isomorph considered as the algebra of sets and parities, and the related properties of functions $f(\epsilon_1, \epsilon_2 \ldots \epsilon_r; \eta_1, \eta_2, \ldots \eta_s)$.

Orthogonal Projection, Model

A New Geometrical Model for the Orthogonal Projection of the Cosines and Sines of Complex Angles, A. E. Kennelly. Proc. Am. Academy of Arts & Sciences, vol. 54, no. 5, Apr. 1919, pp. 371-378, 4 figs. on separate plates. Three-dimensional structure constructed to permit verification of sines and cosines of complex angles by two successive orthogonal projections on to X-Y plane, one projection being made from a rectangular hyperbola, and the other from a circle selected among a theoretically infinite number of non-coplanar circles, all concentric at origin.

Quadrics

On the Deformation of Quadrics (Sur la déformation des quadriques), C. Guichard. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 4, Jan. 27, 1919, pp. 200-204. Homographic transformation of parametric functional quantic. Determination of integral systems by Laplace's method.

Ruled Surfaces

Trajectories and Flat Points on Ruled Surfaces, J. K. Whittemore. Bul. Am. Math. Soc., vol. 25, no. 5, Feb. 1919, pp. 223-229. Determination of points of ruled surface, with real rulings, where curvature of every normal section is zero.

Spiral Minimal Surfaces

Spiral Minimal Surfaces, J. K. Whittemore. Tran. Am. Math. Soc., vol. 19, no. 4, Oct. 1918, pp. 315-330. Study of Minding parallels and meridians of minimal surfaces with reference to Z axis.

Triad System Trains

The Trains for the 36 Groupless Triad Systems on 15 Elements, Louise D. Cummings. Bul. Am. Mathematical Soc., vol. 25, no. 7, April 1919, pp. 321-324. Triad system being regarded as an operator, covariants of that operator are deduced. These covariants are called trains or systems.

The Vapor Tensions of the Metals, J. W. Richards. Jl. Franklin Inst., vol. 187, no. May 1919, pp. 581-598, 4 figs. Vapor-tensi curves, straight-line equation, Trouton's ru and Richards' rule discussed in their appli tion to physical phenomena taking place sherardizing and calorizing.

X-Ray Spectra

Researches on the X-Ray Spectra (Recherches sur les spectres des Rayons X), A Muller. Archives des Sciences physiques naturelles, vol. 1, 5th period, Mar.-Apr. 1919, pp. 127-132, 2 figs. Experimental verificati of law of Einstein.

Pulverized Coal as a Fuel

This Paper Together With the One Which Follows, on Pulverized Coal for Stationary Boilers, and the Discussion Thereon, Represent the Predominating Thought of the Fuel Session Held During the Spring Meeting

By N. C. HARRISON,[1] ATLANTA, GA.

This paper first reviews some of the uses of pulverized coal in the industries—such as the cement, steel and copper industries, and then gives a technical definition of pulverized coal, describes the process by which it is prepared for use and furnishes a table of cost of preparation. The pulverized-coal-burning open-hearth steel plant of the American Iron & Steel Manufacturing Co., Lebanon, Pa., is described and the advantages of pulverized coal, compared with producer gas as a fuel for open-hearth furnaces, are listed.

The use of pulverized coal in stationary boiler plants is discussed, five determining factors in the successful operation of such a plant being taken up in detail. As compared with mechanical-stoker plants the advantages of the pulverized-coal plant are enumerated and certain precautions to be observed with the latter type of plant are brought out.

A report of a test of a 468-hp. Edge Moor boiler with pulverized-coal equipment is included in the paper and the efficiency obtained is compared with the efficiency of a stoker-fed boiler in the same plant, a greater net efficiency being found in the pulverized-coal plant. The paper concludes with a statement of some advantages obtained in the pulverized-coal plant.

THE gradual disappearance of fuels, like natural gas, and the shortage in the supply of crude oils, have compelled in recent years a consideration of pulverized coal as a fuel. Pulverized coal was first used in the United States about twenty-six years ago for the economical burning of cement rock in the rotary kilns of the portland-cement industry and the growth of the industry has had a great bearing on the development and use of pulverized coal. Because of this growth pulverizing machines were also brought to their present high state of development, for in the manufacturing of cement not only is the coal pulverized but for every barrel of cement manufactured (weighing 380 lb.) there are required about 600 lb. of raw material such as limestone shale or cement rock and 380 lb. of clinker produced by the kilns, all of which must be pulverized in order to make the finished product. As there are a hundred million barrels of portland cement made in this country annually, these figures will give one a reason why pulverizing machines have been so highly developed. Fine grinding of the raw material means reduction in the quantity of fuel required and also makes possible the highest quality of the finished product, so far as the chemical analysis or combination is concerned. Fine grinding of the clinker means increased strength for the reason that the hydraulically active units in cement are in direct proportion to the percentage of fine or impalpable powder in the finished product.

The application of this form of fuel has been gradually taken up by engineers connected with other industries, and its recognized value is such that the steel industry today is using in the neighborhood of two million tons of pulverized coal annually in various types of furnaces such as open-hearth, heating, puddling, soaking pits, continuous-heating, reheating, annealing, and forging furnaces.

The copper industry is also using between one and two million tons per year in ore-roasting furnaces, reverberatory and copper-melting furnaces of all types. Large amounts of pulverized coal are used in rotary kilns (other than the cement industry) for the desulphurizing and roasting of various grades of ores; for nodulizing blast-furnace flue dust so as to make available products heretofore very expensive to recover; for burning lime to oxide of lime for use in open-hearth furnaces; for burning dolomite for open-hearth furnaces; and for the calcining of various minerals, from which are obtainable such commodities as plaster of paris, stucco, potash, etc. A total of approximately 10 million tons of pulverized coal are burned annually in the United States in the above industries.

A still further and very important development is now going on, which will, when it attains its growth, require more pulverized coal than probably all of the other industries combined, and that is in its application to locomotives, particularly in the West. There is still another field in which enormous quantities of this fuel will be used and a field in which we are all concerned, and that is in the generation of power in stationary power houses.

Practically any coal can be burned in pulverized form with a proper furnace and burning equipment. Each application however must necessarily be governed by the quality of the fuel available in the district in which it is made. Generally speaking, the coals which give the most satisfactory results are those in which the ash content is less than 10 per cent, the volatile averaging between 30 and 40 per cent and the fixed carbon between 40 and 50 per cent. The sulphur content should be low although coal with a sulphur content running as high as $4\frac{1}{2}$ to 5 per cent is being burned in pulverized form under boilers and without any detrimental results. The ash should have a high melting point. These statements, however, are tentative, as most excellent results have been obtained from all sorts of coals, differing widely from the ideal analysis stated.

What is Pulverized Coal?

From a technical standpoint pulverized coal is that coal which is properly dried, crushed and pulverized so that the product contains the highest percentage of impalpable powder. Merely powdering coal does not fulfill the requirements. Coal must be pulverized so that at least 95 per cent will pass through a 100-mesh sieve having 10,000 openings to the square inch, or in terms of dimension 95 per cent must be less than one two-hundredth of an inch cube.

The average person does not fully realize to what a high degree of fineness it is possible to reduce the coal today by pulverization. The finer the coal is pulverized the more efficiently it can be burned and the more readily it will be diffused when mixed with the air for combustion and fed into the furnaces.

Pulverizing certainly does not change the nature of the coal, but it does change its form to a certain extent in that the coal is changed from a solid into a fuel having liquid properties. As the coal is pulverized it is mixed with air, and when handled in the conveyor it flows like water; when fed to the furnaces it is more or less like a gas, and the furnaces must be designed to burn a gaseous mixture.

Description of a Coal-Pulverizing Plant

A pulverizing plant consists of three main units: a crusher, a crushed-coal drier and a pulverizer, the number of each depending on the size of the plant. The coal is dumped in a track hopper and conveyed by either a belt or apron conveyor into a hopper feeding a single-roll coal crusher, or where slack coal is at hand, direct to an elevator pit. After being crushed to about one inch in diameter, it passes by gravity to an elevator pit, where it is taken by bucket elevators to the drier storage bin. Automatic weighing scales may be installed if desired before the drier storage bin. Magnetic-separator pulleys are also installed (where a belt

A Report prepared for the Atlantic Steel Company, Atlanta, Ga., and later presented at a meeting of the Local Section, Atlanta, and at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form, and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

[1] General Supt., Atlantic Steel Company, Atlanta, Ga. Mem. Am. Soc. M. E.

conveyor is used from the track hopper) to remove iron or steel scrap in the shape of nuts, bolts, pick-points, wedges and such foreign matter, which would interfere with the pulverization.

From the drier storage bin the coal passes to a coal drier. This drier must be of a size to deliver the required quantity continuously and thoroughly dried. The drier is heated either by hand firing on grates or by pulverized coal, so arranged in either case to avoid igniting the drying coal. The cylinder of the drier is rotated by power, either a small motor or line shaft being used. The dried coal falls from the drier through a chute into the pit of an elevator. In this chute the coal passes over another magnetic separator to remove any pieces of metal which might be left in the coal and which were not removed by the magnetic separator previously mentioned.

This elevator carries it to a storage bin set aloft for supplying the pulverizer. By spouts and gates the coal is permitted to enter the pulverizer as desired. This pulverizer grinds the coal to the fineness required. From the pulverizer the coal is conveyed in various ways to the pulverized-coal bins. With the type of mill used at the plant of the Atlantic Steel Company, Atlanta, Ga., the pulverized coal is carried by spouts from the mill to the pit of an elevator, which carries it aloft to the screw conveyor, and the latter feeds the pulverized-coal bins. In another type of mill the finely pulverized coal is conveyed by suction fan from the mill to a cyclone separator, properly located over the pulverized-coal storage bin. This separator will allow the coarser particles to fall back to the mill to be reground, while the fine dust passes to the storage bin. No fine-dust elevator is necessary with this mill.

These pulverized-coal storage bins are of a capacity proportional to the service and hold a supply in excess of the amount required in the intervals when the grinding is not going on. Thus the mills may supply in eight to ten hours all that the furnaces may use in 24 hours.

If the pulverizing plant is located within 200 ft. of the furnaces and the furnaces are of large capacity, these storage bins are located directly at the furnaces, but if there are numerous small furnaces located at a considerable distance from the pulverizing plant, then the storage bins are located at some central point and the pulverized coal conveyed from these points to the various furnaces by means of one of three methods: first, screw conveyor; second, in a mass by means of compressed air; third, in suspension in a current of air.

Costs of Pulverizing Coal

The cost of pulverizing coal depends upon four items: first, the amount of moisture that must be expelled from the coal before pulverizing; second, the cost of labor; third, the cost of coal delivered at the pulverizing plant; fourth, the cost of electricity. Table 1, issued by a pulverized-coal engineering company, gives the cost of pulverizing plants, including buildings, and costs of pulverizing coal in plants of capacity from 10 to 250 tons per day. These figures include all costs, except interest and depreciation, in the pulverizing plant proper, and deliver the dust from the top of the last elevator to the screw conveyor, which feeds the pulverized-coal storage bins.

TABLE 1 COSTS OF COAL-PULVERIZING PLANTS AND COSTS OF PULVERIZING COAL PER TON NET

Tons daily	Total cost pulverizing per ton, dollars	Cost of plant including building, dollars
10	0.56	31,000
20	0.51	31,000
30–40	0.49	31,000
50–90	0.39	37,000
100–130	0.34–0.33	45,000
140–180	0.32	50,000
190–250	0.30	62,000

Pulverized Coal in Metallurgical Furnaces

The development and use of pulverized coal in this country has primarily been due to its application in the cement industry and its gradual application to other types of metallurgical furnaces. Marked economies, and in some cases increased production, have been obtained from this fuel and within the last few years it has been applied very successfully to various kinds of heating furnaces, including forging, continuous-heating, busheling, puddling and open-hearth furnaces. Pulverized coal is also being used on continuous-heating furnaces with very gratifying results, and as a fuel for soaking pits its promises to be used more extensively in the future.

One of the first applications of pulverized coal to the various types of metallurgical furnaces was made by the American Iron & Steel Manufacturing Co., now the Bethlehem Steel Co., Lebanon, Pa., at whose plant this form of fuel was successfully applied to heating, busheling and puddling furnaces, this being practically the first attempt to apply it to the iron and steel industry. Taking into consideration the knowledge obtained from the experience at the above-mentioned plant, and also that obtained from other installations, it has been found that furnaces can be successfully operated by various methods of applying this fuel. Each type of metallurgical furnace presents different requirements as to the kind of burners to be used. Probably the greatest recent development in its use has been as a fuel for open-hearth furnaces and boilers.

All open-hearth furnaces using pulverized coal as a fuel are of the reversing type. There has been only one exception in this country to this, as far as the writer knows, and that exception was at the plant of the American Iron & Steel Manufacturing Co., Lebanon, Pa., where they fired their open-hearth furnaces from one end only. On the other end they installed waste-heat boilers and economizers. As an open-hearth proposition this turned out to be a failure, but as a waste-heat boiler proposition it was a wonderful success. During 1918 they remodeled these furnaces and fired them from both ends.

In the open-hearth furnaces the pulverized coal is delivered into storage bins located at each end of the furnace. On the bottom of these bins are screw feeders, driven by variable-speed motors for supplying the amount of coal desired. This carries the coal by gravity into the burner pipe. These burners are usually a combination of compressed air at from 60 to 80 lb. pressure and fan air at about 8 oz. pressure. In some cases compressed air alone is used as the medium for conveying this coal into the furnaces. The hearth of a pulverized-coal open-hearth furnace is practically the same as the hearth of any other open-hearth furnace but the uptakes, slag pockets and checker chambers are entirely different. The uptakes are made as small as possible so as to hold the gases in the furnace as long as possible without blowing, and the slag pockets are made large so that the gases will have a slow velocity going through them, thereby depositing a large percentage of the heavy particles that are in the outgoing gases. On account of this heavy deposit, removable slag pockets, or very deep stationary pockets, should be used, so as to collect this accumulation over the run of the furnace. Where removable slag pockets are used, they are taken out and cleaned and replaced about every two weeks.

Only one checker chamber is needed on each end of the furnace. If the checker chamber is large enough, these chambers should be built up with large tiles and laid in such a manner as to form vertical flues, having openings of at least 6 by 9 in., or better, 9 by 11 in. In some cases, no checkers at all are used but the chambers are filled with baffle walls with openings from the outside, so that the accumulation between these baffle walls can be raked out. All passages from slag pockets to stack must be as straight as possible and wherever any bends must be made, some agitating device should be installed at these points. The reversing valves are usually of the mushroom and damper-slide type.

The best coal for use in pulverized form in open-hearth practice is a bituminous coal as high in volatile matter as possible, and preferably low in ash. It should never contain below 32

per cent of volatile, nor more than 8 per cent of ash. For open-hearth furnace use it is necessary that the coal be as finely ground as possible and it should be so fine that about 97 per cent will pass through the 100-mesh sieve, preferably 90 to 93 per cent and not less than 85 per cent through the 200-mesh sieve, and from 70 to 75 per cent through the 300-mesh sieve.

This very fine pulverization is necessary for quick combustion and for the removal of sulphur in the coal; and in order to obtain this complete combustion before the flame strikes the bath, some 6 or 8 ft. are necessary from the end of the burners to the bath.

Pulverized Coal vs. Producer Gas

The advantages and disadvantages from the use of pulverized coal, as compared to gas producers, as a fuel for open-hearth furnaces, from observation of its use up to date are as follows:

a Since the coal is of a more even chemical composition all the heat units are consumed in the furnace, while in the case of the gas producer from 18 to 25 per cent of the heat units are lost in the producer itself when converting the coal into gas. This will result in a greater number of heats per week.

b Open-hearth furnaces using powdered fuel operate on a very low fuel consumption equal to the best producer-gas practice, and much better than the average of the older plants in this country; at the writer's plant (The Atlantic Steel Company, Atlanta, Ga.) about 50 per cent less.

c Coal can be pulverized in plants of about 100 tons daily capacity and delivered to the furnace for approximately 50 cents per ton, which is about the same as the costs for gasifying coal in gas producers.

d Although the use of this fuel in metallurgical furnaces has been developed only about 75 per cent, it is believed that this development is steadily increasing. In the writer's plant the pulverized-coal open-hearth furnace has been shut down more often than the producer-gas furnace of the same size. This has been due to checkers and slag pockets filling up with cinders and slag after about 80 heats; these troubles, however, are being gradually overcome by decreasing the size of the uptakes and enlarging the slag pockets, thereby holding the gases in the furnace longer and passing them slowly through the large slag pockets, so that the heavy particles can settle, and now only the fine particles are going to the checkers, which particles are being blown off daily by compressed air. By these means it is expected to get a much longer life out of the checkers, and consequently longer runs out of the furnace, since the filling up of the checkers has always been the deciding factor in the length of run of the furnace.

e Sulphur does not give any trouble as long as there is a good draft and the furnace is working hot, as this plant is now using over 1 per cent sulphur in its coal and getting good results, although when checkers get clogged up and the furnace begins to blow, due to lack of draft, there is trouble with the bath taking up sulphur. This takes place during the last week's run of the furnace, just before it goes down for repairs.

f The pulverized-coal open-hearth furnace is under complete control of the first helper as to the amount of coal being used at all times, air blast and temperature.

g The flame, using the same coal as on gas producers, is hotter, which allows the use of a greater percentage of scrap per ton of steel, thus reducing the consumption of high-priced pig iron.

h The finished steel is quieter in the molds, due to not being overly oxidized, as the coal coming directly in contact with the bath has a greater reducing action. All gas-house troubles are eliminated (cleaning fires, burning out flues, etc.) although the pulverizing plant must be given attention as to dryness and fineness of coal.

i Up to date, the refractory costs have been very much greater on the furnace using pulverized coal than on the gas-producer furnaces and was almost twice as great a year or so ago, although the writer believes that on account of the steadily increasing development of the use of this fuel, these refractory costs will be steadily decreased.

Table 2 shows a comparison of fuel costs for all fuels now used on open-hearth furnaces and it will be seen that natural gas is not only the ideal fuel but is the cheapest.

Pulverized Coal in Stationary Plants

Many engineers who attempted to burn coal in pulverized form obtained unsatisfactory results, and concluded it was "impossible." In many of the earlier trials to burn pulverized coal under boilers the usual method was to install coal-feeding devices of some kind in the furnace as it stood, with the result that the fire bricks melted down and the tubes were plastered with unconsumed carbon, ashes and soot. So destructive were the results

TABLE 2 FUEL COSTS FOR OPEN-HEARTH FURNACES

Kind of fuel	Remarks	Amount per ton steel	Rate cost fuel, dollars	Cost of fuel and labor, dollars	Cost per ton steel, dollars
Natural gas..	....	6000 cu. ft.	0 04 per M	....	0.24

[2] Tar is a waste product at some plants and has to be burned.

that those making the tests can hardly be blamed for arriving at the conclusion they did. How close some were to success was not fully realized. Conditions were not ripe. Today results are being obtained that are of sufficient importance to warrant careful investigation and consideration.

For the proper combustion of coal under boilers, there are five main points which must be given serious consideration, otherwise the burning of this fuel will not be a success. These five points are coal fineness, size of combustion chamber, necessary air opening, proper damper regulation, and clean tubes.

Coal Fineness. The pulverized coal should run about 96 per cent through the 100-mesh screen and about 85 per cent through the 200-mesh screen. If it runs below 80 per cent through the 200-mesh screen, particles of carbon will fly through the air inside of the combustion chamber, and as these particles are not completely burned when the gases reach the tubes, they will deposit themselves on the tubes. These heavy particles in the pulverized-coal mixture will sometimes settle on the bottom of the combustion chamber and will soon build up in the shape of stalactites. This accumulation will continue to build until the bottom of the combustion chamber continues to be raised, until it comes in contact with the flame. These built-up particles will then fuse into a solid mass, which, in a very short time, will cause a shut down of the boiler to dig this fused mass out. It is, therefore, necessary, for the successful burning of this pulverized fuel under boilers, to have this coal as finely pulverized as possible.

Size of Combustion Chamber. Before installing, or considering the use of pulverized coal under boilers, a study of the boiler-house installation should first be made, the rating at which the boilers will be operated decided upon, considering any peak load which may develop. The combustion chamber should be designed large enough to take care of the maximum loads which will be developed from the boilers at any time. After this maximum rating has been determined, the combustion chamber is designed, using a cubical capacity equivalent to approximately 50 cu. ft. per lb. of coal burned per min., or approximately $2\frac{1}{2}$ cu. ft. per hp. developed by the boiler. If it is decided to run this boiler at 150 per cent of this rating and the combustion chamber is designed accordingly, the efficiency will not be decreased perceptibly if the boiler is run under this 150 per cent rating, but if over a 150 per cent of the rating is developed serious difficulties will result. More coal and air must be admitted to the boiler to develop the greater rating, and consequently more combustion space is needed; and finally if this combustion space is not available the flames impinge on the brickwork and cut it away very rapidly. Also, combustion is not complete at the time the gases strike the bottom row of tubes and consequently the gases will pass up the stack unburned. Efficiency is then decreased. The size of the combustion chamber should also be so designed that the velocity of the gases should not pass through this combustion chamber at a speed of more than 6 ft. per sec. The mixture of air and coal entering the combustion chamber, as stated above, should be at as low a pressure as is possible to

bring this mixture in in suspension; or, in other words, breathe it in.

Proper Air Openings. The pressure at which the pulverized coal is admitted to the furnace is as low a pressure as can be used to carry this fine coal in suspension, and is about half an ounce pressure at the nozzle. In some installations the coal falls by gravity from the variable-speed screw conveyor, located on the bottom of the pulverized coal bin, into a fan air line which carries it into the furnace and also supplies the necessary air for combustion. Some few openings are placed in the front wall of the boiler to give any additional air which may be needed, and a few may also be placed on the side walls of the boiler to protect the brickwork at times.

In other installations the amount of air necessary to convey the coal into the furnace varies, according to the rate at which the boiler is being operated. The balance of the air to burn the coal properly is admitted through adjustable air openings in the front, sides and bottom of the combustion chamber. These openings are made adjustable and are placed on all sides of the combustion chamber to take care of the various grades of coal which may be used in the boiler plant. By properly observing the combustion in this chamber, by a little experience the fireman knows at exactly what points to give more, or less air needed for combustion.

Damper Regulation. In order to give the proper velocities of gases passing through the combustion chamber, it is necessary to have very accurate damper regulation to take care of the various load conditions which the boiler is to supply. The damper should be so regulated that it will maintain practically a balanced draft inside of the combustion chamber and only a slight vacuum in the first pass, while at the damper itself not more than 0.10 to 0.15 in. is required. If there is more vacuum than this, it pulls the gases through the combustion chamber too fast, causing them to be unburned before reaching the first row of tubes and will then build up very fast on the outside of these tubes. This very small draft needed at the base of the stack will allow us to operate boilers using pulverized coal with stacks of about 30 to 35 ft. in height.

Clean Tubes. In order to get the maximum evaporation from any boiler it is necessary that the tubes be kept clean. They should therefore be blown at least every 6 hours. Once every 24 hours the bottom of the first row of tubes should also be blown as these are the tubes in which the gases come into contact first after leaving the combustion chamber. This material can be blown off easily if the combustion chamber has been properly constructed and if the tubes are blown regularly as needed. If they are not blown regularly this material accumulates very fast and in time will become fused and cannot be blown off.

Another item, which might have been called the sixth point, is the removal of ash which deposits at the bottom of the combustion chamber. This ash should be removed at regular intervals, which intervals will be determined by the amount of ash in the original coal. If the ash is not removed regularly, it will build up until it comes in contact with the flame, when it becomes fused and has to be dug out. But if removed at regular intervals, it can be easily raked out with the ordinary boiler-room ash rake and will not consume more than half an hour per 24 hours, and will not interfere with the operation of the boiler while this is being done.

Pulverized Coal vs. Stokers

The following are some advantages of pulverized coal as a fuel for boilers over stokers:

a Much wider variation in the quality of the coal usable is obtained when burning coal in pulverized form. Practically any and all grades of coal can be burned in this form with economy.

b The ability to take care of peak loads almost instantaneously. In other words, a pulverized-coal burning system is much more flexible than a stoker installation. Its flexibility approaches that of oil or natural gas.

c The amount of coal that can be burned per square foot of grate surface on stokers is limited so that for increased capacity the boiler setting must be spread out to cover more area. When using pulverized coal, this condition does not exist, for proper furnace conditions can be obtained by increasing the height of the boiler setting or the depth of the combustion chamber.

d By throwing a switch the entire firing operation ceases; an advantage in case of accident or emergency.

e Ash is in much better condition to handle. The ash is in the form of a dust or slag depending upon its melting point. This helps to maintain constant furnace temperature as there are no interruptions to firing conditions on account of cleaning fires.

f Pulverized coal is fired dry, containing less than 1 per cent of free moisture, whereas coal burned on stokers may vary anywhere from 1 to 10 per cent, of free moisture as fired.

g Considerably less excess air is necessary for complete combustion. This item is of the utmost importance when making comparisons. Less excess air means less power for furnishing air supply, particularly where forced draft is used. With less excess air the stack losses are less. Lower grades of coal fired on stokers require more excess air as it is quite difficult for the oxygen to get in close contact with the combustible. An air supply sufficient to furnish all the air for combustion should be available, although at times only 50 per cent of the air is necessary to be injected into the furnace with the coal, the balance being supplied by the induction action of the burner or drawn in by the stack draft through the various adjustable openings in front and sides of combustion chamber. The air going into the furnace should be under control to permit close regulation under all conditions of firing.

h With furnace properly proportioned and with properly designed burning equipment smokeless operation may be maintained indefinitely. This is due to complete combustion of all the particles of coal before coming in contact with the cold surface of the tubes of the boiler.

The following few points must be kept in mind for the successful burning of pulverized coal under boilers:

a A boiler furnace using pulverized coal should have as few burners as is possible consistent with good regulation. The burners must be proportioned for the maximum rating of the boilers, and they must be adjustable. Simplicity of design is desirable. It has been found much more desirable to introduce coal into the furnace as far away from the side walls as possible so that the rapid continuous expansion of the gases will not develop high velocities in close contact with the furnace refractories. Furnaces under boilers should be proportioned so that the velocity of the gases should not be excessive, particularly at the smallest cross-sectional area of the furnace. Vertical baffles should replace all horizontal baffles.

b A boiler of any size can be fired successfully with pulverized coal. Various designs and makes of boilers can be readily arranged for pulverized-coal firing, but those containing the smaller percentage of space for the lodgment of ash are preferable.

c Feeders for regulating the flow of pulverized coal to the furnace must be designed so that at all times the variation in quantity will be directly proportional to the speed of the screw and no flooding allowed. The speed of the feeder should be so regulated that operating at its maximum r.p.m. the supply of pulverized coal to the furnace will not exceed the capacity of the furnace. Soot blowers should be installed in settings where pulverized coal is used.

d The equipment for using pulverized coal is standard for any grade of coal so far as handling, preparing and delivering to the furnace is concerned. Only a slight change is necessary in the furnace to take care of coals of very low volatile content, such as anthracite, culm and coke breeze, and increased drying capacity is desirable when lignite coal is used. With stokers this is not the case as the varying quality of coals require different type stokers to obtain highest efficiency.

Test of a Boiler Using Pulverized Coal

The following is a report of a test made on a 468-hp. boiler using pulverized coal as fuel. This installation is noteworthy not only by reason of the high efficiency obtained, but also because of the fact that it has made clear some of the conditions necessary for the successful operation of boilers utilizing powdered fuel.

When the boiler was first put into operation, a number of undesirable conditions resulted. An insufficient air supply caused high furnace temperature resulting in fusion of the ash particles and a consequent accumulation of slag between the tubes, on the furnace walls and in the ashpit. The removal of the molten slag presented considerable difficulty. It was also found that the combustion chamber was of insufficient size. High gas velocities resulting from insufficient air in the chamber tended toward destruction of the refractory surfaces of the furnace.

A new furnace was therefore designed. The combustion chamber was enlarged and a regulated air supply was provided for by means of a number of auxiliary air openings equipped with dampers. The accumulation of slag in the pit was prevented by raising the point of admission of the fuel into the

furnace. As a result the flame path has been raised above the base of the pit, hence particles of ash dropping from the flame are not fused. The ash, therefore, can be drawn from the pit in the form of a powder and small slugs of slag. Analysis has shown that the ash contains practically no carbon.

Having established satisfactory furnace-operating conditions, a series of efficiency and capacity tests were conducted preliminary to proving the contract guarantees. The brickwork was then given a thorough trial by carrying the boiler at a continuous rating of 180 per cent over a period of several days. On August 12 and 13 a final efficiency test was made. The results are given in Table 3. The boiler is a three-pass water-tube boiler, equipped with a superheater.

At this same plant are other boilers fired by one of the most efficient types of underfeed stokers. A comparison is made between results of above test and tests made on the stoker-fired boilers.

Pulverized Coal vs. Mechanical Stokers

Under this heading fuel-preparation costs will first be considered. In the case of powdered coal this can be classed under three general divisions:

a The cost of crushing the coal. This expense is the same for pulverized-coal equipment as for stokers.

b The cost of drying and pulverizing the coal. Although no cost records are available at present, it is estimated that 32 cents per ton will cover this preparation cost on a 200-ton-per-24-hr. plant using bituminous coal containing about 12 per cent moisture.

c The maintenance costs of the drying and pulverizing plant. This unit has not been determined from actual experience; however, it is estimated that 3 cents per ton will cover the maintenance. In stoker practice the maintenance cost per ton of fuel fired is close to 5 cents per ton.

TABLE 3 LOG OF TEST OF A PULVERIZED-FUEL-BURNING STATIONARY BOILER. DATE AUGUST 12–13, 1918

Make of boiler				Edge Moor
Rated hp				468
Heating surface, sq. ft				4685
Time fired or test started				11 15 a.m. 8/12/18
Time fire out or test finished				11 15 a.m. 8/13/18
Duration of test hr				24
		Maximum	Minimum	Average
Temperature of boiler room, deg. fahr		99	85	93.3
Temperature of feedwater		168	135	157.2

Motor operation, kw-hr				449.3
Coal equivalent at 3 lb. per kw-hr., lb				1,348
Total deduction, lb.				2,488
Resulting net efficiency, per cent				81.1

[1] No deduction made for stand-by losses in drier.

Summarizing the above facts it is evident that, with fuel at $5 per ton, the gross efficiency shown by the pulverized-fuel boilers will have to exceed that shown by the mechanical-stoker-fired boilers by 6 per cent in order to offset coal-preparation costs. A 6 per cent deduction from a gross efficiency of 85.22 per cent results in a net efficiency of 79.22 per cent for the powdered-coal burner. In stoker practice the maximum attainable gross efficiency at any of our plants has been 80.54 per cent. Deducting the 2.5 per cent for auxiliary uses, the resulting net efficiency is 78.04 per cent, which is lower by 1.18 per cent than the figure obtained in pulverized-fuel practice.

Other advantages resulting from the use of pulverized fuel are summarized herewith:

a Continuous boiler operation at a uniform rating as well as a constant efficiency is made possible. At no time is there a loss in capacity due to the clinkering of coal on the grates or the cleaning of fires, as is the case in stoker practice.

b Heavy overloads can be taken on or dropped off in a very brief time through adjustment of the coal feeders and the furnace drafts.

c From 97 to 98 per cent of the combustible in the coal is utilized, regardless of the quality of the fuel.

d The ash-handling costs are reduced to a minimum due to the reduced volume.

e The banking conditions when operating with pulverized coal are somewhat different from those obtained in stoker practice. By stopping the fuel supply and closing up all dampers and auxiliary air inlets a boiler can be held up to pressure for about 10 hr. The furnace brickwork having been heated to incandescence during operation gives off a radiant heat which is absorbed by the boiler rather than being sent out through the stack. The ease of controlling the fuel, feed and drafts, the ability to take on heavy overloads in a brief time, the thorough combustion of the coal and the uniform high efficiency obtainable under normal operating make pulverized coal a most satisfactory form of fuel for central station uses.

The full story of maintenance expense is only partly known, however, but all indications are that no unusual difficulties will be met. The cost of fuel preparation and labor for operating a boiler room fully equipped with pulverized-coal-burning boilers will be a question for the engineer to decide for himself according to his particular conditions. If properly installed with respect to capacity of storage, size of drier and pulverizers, and on a sufficient number of boilers to properly and fully employ the minimum number of men, the pulverized-fuel installation will undoubtedly be more advantageous. The main item that must be borne in mind by engineers is that the ease with which a high efficiency is obtained and the constant nature of that efficiency, as compared to the lack of constancy of efficiency in a stoker-fired boiler, unless very closely supervised, is the one factor which justifies the burning of pulverized fuel. There is no doubt that with a well-equipped plant burning pulverized fuel, having all the necessary recording and indicating instruments to guide the operators in maintaining the proper conditions, a lower cost of generating steam will be possible than has heretofore been the case in any type of equipment.

Pulverized Coal for Stationary Boilers

By FRED'K A. SCHEFFLER,[1] NEW YORK, N. Y., and H. G. BARNHURST,[2] ALLENTOWN, PA.

It is the purpose of this paper to present those facts which the authors believe indicate the coming general adoption of pulverized coal as a fuel for boilers. Since stoker firing is the most efficient method when solid fuels are used, a comparison of stoker and pulverized-fuel plants is given, with particular reference to reliability, cost, adaptability and efficiency. The cost of pulverizing coal and the cost of stoker operation are discussed in detail and tables given showing results of tests on pulverized-fuel plants and data regarding boiler installations using pulverized coal as a fuel.

Although a very great interest has been aroused throughout this country and abroad in the adaptation of pulverized coal to boiler furnaces, it is remarkable how little is known, in a practical way, of what is actually being done, how it is accomplished, and what results have been obtained. The purpose of this paper is therefore to set forth the facts which indicate the coming general adoption of pulverized coal as a fuel for boilers, the discussion being presented in the form of a comparison with stoker firing—the most efficient method in general use for burning solid fuel under boilers. It is hoped that the data and illustrations presented will prove of interest and will call forth discussion which will serve to develop further this study of the best method of reducing power-operating costs.

The ultimate adoption of a new method depends entirely on its overall commercial efficiency. In the generation of power, overall efficiency may be considered as composed of the following factors: reliability, cost and adaptability. A method may acquire a wide field if it shows improvement in any one or two of these points. Improvement in all three points leads to the general superseding of other methods.

Reliability. This factor depends on two items: apparatus for preparing and presenting the fuel for combustion, and continuity of operation of the furnace itself. In a stoker installation the first of these includes the stoker itself. Neglecting the inherent defects of any system that presents a metal mechanism to the action of high temperatures, it may be admitted that the stoker system is satisfactorily reliable, with respect to its apparatus, for preparing and presenting the coal for combustion.

The corresponding mechanisms for pulverized fuel are equally reliable. This fact is proved by their widespread use for years in the cement industry and more recently in an ever-increasing variety of industries. It should be recognized that these mechanisms are not innovations, but are the result of years of development under operating conditions. Proper design of equipment by engineers of standing who are specialists in this line has made negligible the danger of dust explosions, the occasional occurrences of which in years past have furnished ammunition to the opponents of pulverized fuel.

The second condition for reliability is the continuity of operation of the furnace. Here again there will be found an apparent balance between stoker and pulverized-fuel installations. The advantage, however, lies with pulverized fuel, and for several reasons. The mechanism is altogether outside the furnace, hence cleaning and adjustment and the making of the few repairs required need not interrupt the operation of the boiler. In case of sudden necessity the fire may be ignited and quickly brought to full intensity, or it may be extinguished almost instantly. The greater uniformity of flame and temperature is also conducive to longer life of the furnace lining in a properly designed furnace, and to a minimum variation in furnace efficiency. Finally, the pulverized-fuel installation relieves the power plant from dependence upon the availability of a certain grade of coal. Stokers will not handle all grades of coal.

Cost. This second factor refers to the cost per B.t.u. delivered to the boiler. The various items entering into this cost by the stoker system comprise power, repairs and maintenance, labor, interest on investment, depreciation, insurance and taxes.

With pulverized-coal equipment the cost of fuel for the drier should be added to the preceding items, as it is clearly cheaper to remove the excess moisture content from the coal in a drier, from which the gases leave at very low temperature, than in the furnace itself, where the evaporation of the moisture damps the fire, increases the content of inert gases and carries off a very perceptible amount of heat.

Returning to the balanced cost items, it appears that these show a saving in favor of pulverized fuel in a large power plant and for the stoker in a small power plant. The figures in question are discussed further on in detail. It should be noted that when central pulverizing plants are built they will relieve small power plants of the necessity for maintaining pulverizing equipment and will make pulverized fuel considerably cheaper than stoker-fed fuel, regardless of the size of installation. This feature is already being carried out successfully.

The final item of the cost, namely, furnace efficiency, which governs all the others, results in all respects to the advantage of pulverized fuel for the following reasons:

First: The fuel enters the combustion chamber in a finely divided state, being introduced with air at low pressure, and is approximately perfectly mixed with the air for theoretically perfect combustion. Therefore no excess air is required for complete combustion. Should it be desired for other reasons to introduce excess air with pulverized fuel, it can be done in exact amounts, evenly distributed, without affecting the uniform nature of the flame and flue gases. This uniformity, which cannot be obtained in either grate or stoker installations, means maximum efficiency in all parts of the furnace and a maximum rate of heat transference to the boiler throughout its exposed area. It also means that flue-gas analysis gives an accurate determination of conditions in the furnace, and that control of coal delivered and air supply can be adjusted with great accuracy.

Second: In pulverized form all of the combustible is burned, a consummation certainly impossible in lump-coal firing by either hand or stoker. It is not unusual to find 20 to 30 per cent of carbon in ash refuse from grate- or stoker-fired boilers.

Third: With pulverized fuel there are no stand-by losses, either with change of load or when shutting down, such as banked fires, etc.

Fourth: With properly designed pulverized-fuel apparatus nothing of a mechanical nature takes place in the furnace. In stoker and grate firing not only is the mixing with the air done in the furnace, but the presentation of fresh surfaces of combustible to the air supply must take place by the removal of the ash and its discharge through the grate bars, or the pressure must be great enough to force the air supply through the ash bed.

Adaptability. The third factor of overall efficiency is adaptability. Pulverized fuel is here preëminent. The primary feature is the possibility of burning all grades of fuel without affecting the efficiency of the furnace. To burn anthracite and very low grades of fuel requires a furnace allowing a return flow of the flame past the incoming flame, to heat up the incoming fuel, and in a furnace of this type fuel containing over 50 per cent ash has been burned with high efficiency.

The flexibility in the use of pulverized fuel is perfect, and the fire may be instantly adjusted to suit any condition of overload or lower load, including the cutting in and out of the boilers. The paramount importance of this feature and the utter impossibility of approaching it with stoker or grate firing is readily evident. Furthermore, the operation and the determination of conditions for complete combustion may be made automatic, the result being a smokeless and sootless boiler plant, which is essential in modern cities.

Presented at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

[1] Manager Pulverized Fuel Dept., Fuller Engineering Co.

[2] Chief Engineer, Fuller Engineering Co.

Furnace Design. The primary requisite for good results is to maintain low velocities in the furnace in order to avoid damage to the linings and their erosion. A furnace cubical in shape usually gives the most satisfactory results. The burners should inject the coal under low pressure and should permit of varying the density of the mixture in the burner itself. Their location and number will depend upon the size of the boiler and rating required, and also may be varied to suit the grade of fuel. High boiler ratings such as are used in modern boiler practice can be obtained when desired, and such overratings should be predetermined and the furnace volume designed accordingly.

In Table 1 will be found an itemized statement of the costs of pulverizing coal, and in later paragraphs some statements as to the cost of stoker operation for purposes of comparison. Table 2 gives reports of preliminary tests made on some of the pulverized-fuel installations now in operation. A third table in the complete paper gives particulars regarding 19 installations since August 1916, comprising 96 boilers of various types and sizes ranging from 100 to 600 hp. and aggregating 25,000 hp. in capacity. While these do not show the maximum efficiency to be expected with the further development of the art, they nevertheless indicate that the inherent difficulties have been solved and that at the present moment pulverized fuel is in a position to compete advantageously with any other method of burning solid fuel under boilers.

TABLE 1 COST OF DELIVERING PULVERIZED FUEL TO BOILERS

	100-ton plant, dollars per net ton	1000-ton plant, dollars per net ton
Power at ¾ cent per kw-hr. and 17 kw-hr. per net ton	$0.1275	$0.1275
Labor at 40 cents per hr	0.14	0.04
Drier coal at $5 per net ton delivered	0.06	0.06
Repairs	0.07	0.07
Total actual cost of pulverizing per net ton	$0.3975	$0.2975
Interest at 6 per cent	0.105	0.039
Depreciation	0.12	0.04
Taxes and insurance	0.035	0.013
Total cost per net ton	$0.6575	$0.3895

Comparison on an Efficiency Basis

One of the most prominent engineers in this country, a member of the Society, has stated that the combined boiler and furnace efficiency by the month, day in and day out, of a modern stoker-fired power plant with the best average plant operation is not better than from 63 to 65 per cent, although a carefully conducted test on one boiler and furnace might show during several hours' run 75 per cent efficiency. This statement has been confirmed by other engineers. The results with pulverized fuel, however, would be totally different. There is no apparent reason why a combined furnace and boiler efficiency of 75 per cent, and even higher, could not be maintained throughout the year, as the operation of the plant would be practically equivalent to that of a fuel-oil installation, in which stand-by losses, banked fires, etc., are almost entirely eliminated. Unquestionably there should be a saving, under these circumstances, of 12 to 15 per cent of the total coal consumption in favor of pulverized coal, and this reduction, on a basis of even a 2000-boiler-hp. plant, will show a very fair return on the investment, neglecting the fact that a lower-grade and cheaper coal could be used.

Cost of Pulverizing Coal

The cost of pulverizing the coal is of prime importance, as low costs are essential for success and are achieved when the quantity used per day of 24 hr. exceeds 100 tons. The cost of pulverizing is made up of a number of items, namely, power, repairs, coal for drying, labor, interest, depreciation, taxes and insurance.

Power. The power required in an up-to-date pulverized coal plant is from 12 to 13 kw-hr. per net ton of coal crushed, dried and pulverized. The additional power required for transferring the coal to the point of use and feeding it to the boilers will vary considerably, depending upon the distance transported, the size and number of the boilers, and the conditions under which they operate. The power required for this latter purpose varies between 4 and 6 kw-hr. per net ton, so that the total power for the entire process from the track and storage delivered to the boilers is 17 or 18 kw-hr. per net ton. In the following paragraphs the cost of power has been assumed at ¾ cent per kw-hr.

Repairs. The item of repairs, including material, labor and general upkeep of the plant or maintenance, for the entire pulverizing plant and burning equipment will vary from 7 to 10 cents per net ton of coal handled. The figures depend upon local conditions and the size and general arrangement of the entire installation.

Coal for Drying. This item depends directly upon the percentage of moisture and upon the price of coal. Ordinarily only from 1 to 1¼ per cent of the total amount of coal used is required for drying. Assuming coal to have an average of 7 per cent moisture as received and the cost to be $2.50 per net ton, the cost per net ton of drying the coal will be 3 cents. At $5 per net ton the cost of the drier coal will be 6 cents.

Labor. This item is the greatest variable in connection with the pulverizing of coal, due to the increased output that can be obtained in larger plants per man employed. It is also subject to local rates of wages. For example, assuming labor at 40 cents per hour, a plant of 100 tons daily capacity, properly designed

TABLE 2 REPORT OF PRELIMINARY TESTS MADE ON PULVERIZED-FUEL PLANTS

Date of test	Location of plant	Duration, hr.	Coal used	Efficiency maintained, per cent	B.t.u. per lb. of coal as fired	Ash, per cent	Rating per cent

and equipped, will require approximately 34 labor hours to prepare the fuel and deliver it to the conveyors, whereas in a plant having a daily capacity of 1000 tons, approximately 115 labor hours are required. Therefore the labor cost would be 14 cents per net ton in a 100-ton plant, only 4 cents per net ton in a 1000-ton plant, and as low as $2\frac{1}{2}$ cents per net ton in a plant of 5000 tons daily capacity.

Interest. The interest item is based on 6 per cent of the entire investment, and the cost of the pulverized-coal plant and burning equipment will of course vary considerably with the conditions under which the plant is installed. Roughly speaking, however, the actual investment will vary from $12.80 per kw. output in a 5000-kw. plant down to $4.80 per kw. in a 50,000-kw. plant and $4.12 in a 100,000-kw. plant (assuming a turbo-generator water rate of 16 lb. and continuous boiler and furnace efficiency of 75 per cent).

All these figures in relation to cost are based on the present high prices. The investment required for a 5000-kw. plant using 100 tons of pulverized coal daily is approximately $64,000 and for a 50,000-kw. plant using 1000 tons of pulverized coal daily, approximately $240,000, so that, on a basis of 6 per cent and allowing for 365 days' continuous operation, the interest item will vary from $10\frac{1}{2}$ cents per net ton in a 100-ton plant down to 3.9 cents per ton in a 1000-ton plant.

Depreciation. Depreciation in a coal-pulverizing plant is usually calculated as follows: The life of the building is considered as 40 years, of the coal driers as 15 years and of the remainder of the equipment as 20 years. With a 100-ton pulverized-coal plant and burning equipment the depreciation item will be approximately 12 cents per net ton, and in a plant of 1000 tons daily capacity it will be approximately 4 cents per net ton.

Taxes and Insurance. Taxes and insurance are based on 2 per cent of the entire investment, and for a 100-ton plant this item is approximately $3\frac{1}{2}$ cents per ton and for a 1000-ton plant, 1.3 cents per ton. Summarizing, the foregoing results show that the total cost of pulverizing and delivering pulverized coal to boilers is approximately as given in Table 1. The cost of the pulverizing equipment complete compares favorably with the stoker equipment when everything, such as coal- and ash-conveying machinery, etc., is taken into consideration, and in large plants it is considerably less.

Cost of Stoker Operation

The equipment required for a first-class stoker installation must necessarily be taken into consideration when making a comparison of the costs of the different installations. The cost of pulverizing is an item of expense which must be included with the cost of the fuel, and since it includes the complete handling of the coal, the expense of crushing, handling, power, repairs, maintenance, interest, taxes and insurance covering the stoker equipment must also be considered when making comparisons.

Stoker installations and operation are expensive and the investment is as great, if not greater, than that required for a pulverizing equipment in plants of 10,000 kw. and upward. For example, in a plant using 1000 tons in 24 hours the cost of operation will be approximately as follows:

Power for stoker, 2 per cent of the total boiler hp. developed..	$180.00
Power for fans, 2 per cent of the boiler hp. developed.......	180.00
Coal handling, 100 kw. at $\frac{3}{4}$ cent per kw-hr...............	18.00
Labor for coal handling, 2 men per shift and 3 shifts at 40 cents per hour	19.20
Repairs for stokers at 30 cents per boiler hp. per annum....	17.50
Repairs for coal-handling equipment......................	10.00
	$424.70
Total cost per net ton.......................$0.425	

To this must also be added the cost of fuel used to heat the moisture in the coal, interest, depreciation, insurance and taxes, showing that even on a basis of equal efficiency the cost of operating a pulverized-coal equipment is considerably less than the cost of operating an equivalent stoker installation. It should be stated that the figures just given are based on present average results in both cases.

DISCUSSION AT FUEL SESSION OF SPRING MEETING

The Fuel Session of the Spring Meeting was held on the morning of Thursday, June 19, Vice-President John A. Stevens officiating as chairman. Three papers were presented at this session: namely, Pulverized Coal as a Fuel, by N. C. Harrison; Pulverized Coal for Stationary Boilers, by Fred'k A. Scheffler and H. G. Barnhurst; and Economy of Certain Arizona Steam-Electric Power Plants Using Oil Fuel, by C. R. Weymouth. The latter paper, which was presented by title only, was published in Mechanical Engineering for June, p. 523; the two papers on pulverized coal, which were jointly discussed, appear elsewhere in this issue. Extensive extracts from the discussions of these papers immediately follow.

Discussion of Papers on Pulverized Coal

Thomas A. Marsh[1] (written). The writer would preface his discussion by the statement that the general proposition of taking raw coal with all of its by-products and preparing it to the most expensive size (pulverized) and then burning still raw coal and losing the by-products, appears to be a move very much in the wrong direction. Pulverized coal has a field, no doubt; for instance, such fuels as lignites as cannot be burned on stokers. This field is limited, however, for chain grates are now developed to burn lignites containing 30 to 35 per cent moisture, which embraces practically all but those of the North Dakota field.

Pulverized fuel is adaptable to certain processes as the cement process and certain metallurgical processes. In substantiation of its adaptability for steam boilers, however, the paper by Messrs. Scheffler and Barnhurst represents pulverized fuel at its best, hints at not a drawback or trouble, submits tests of four or five hours' duration and evidently not made under the A. S. M. E. code, and contrasts stokers of the most expensive type to operate as to power to drive and as to power for fans. If it is necessary to resort to such extremities to make a comparable showing for pulverized fuel, it cannot be said that it is on a competitive basis with modern automatic stokers and furnaces.

The following discussion and questions are submitted in the hope that the full answers thereto will provide facts on which to base conclusions in accordance with the Society's past standards.

Reliability. Under the item of "Reliability" in the above-mentioned paper it is stated unqualifiedly that the mechanisms for pulverizing fuel are equally reliable with those for crushing coal for stokers. The extra equipment necessary for this exceedingly elaborate preparation of the fuel is another link to the mechanism (and a high-speed one at that), and I think no engineer will agree that the combination of a crusher system and a pulverizing system is as reliable as a stone crusher alone. Even if this complex system were equally reliable as a crusher, which it is not, the station dependent on pulverized fuel would suffer shutdowns unless the crusher and pulverizer equipment were duplicated. The writer understands that cement plants are usually equipped with duplicate pulverizing systems. This will all have a bearing on investment charges.

Further, it is stated in the paper that all grades of coal can be used. There are stokers which have limitations only on anthracite or coke breeze and in this connection the question arises as to whether a pulverized-coal furnace and burner designed for, say, bituminous 35 per cent volatile will burn anthracite or coke breeze. I ask this because in one of our other technical societies it is a matter of recent record that for burning low-grade

[1] Chief Engineer, Green Engineering Co., Chicago, Ill. Mem. Am.Soc.M.E.

anthracite or coke breeze in pulverized form, reversal of the flame is necessary, a firing method not suitable for the richer bituminous coals. It was also brought out that with coke breeze or anthracite culm the fire was unresponsive and the load had to be varied to suit the fire rather than the fire to suit the boiler load. What occurs when a rich high-grade fuel is used in a furnace and burner designed for low-grade fuels?

Adaptability. Under this heading the authors state that the primary feature is the possibility of burning all grades of fuel without affecting the efficiency of the furnace. In order for this to be true, it is necessary to burn the 50 per cent ash coal with no more excess air than the 3 per cent ash coal and suffer no more ashpit loss in the former case than in the latter. The writer therefore specifically asks if the 50 per cent ash coal requires in practice no more air than the 3 per cent ash coal. When 50 per cent ash coal is used the sensible heat of this amount of refuse leaving the furnace chamber is in itself an item which will affect the efficiency of the furnace. Can efficiencies be independent of these items? The tests show wide variation in efficiencies. What causes these wide variations?

Chain grates are burning coals containing 35 per cent ash and producing some excellent results, and have been for years. It would be desirable along with this statement by the authors regarding high-ash fuels for them to submit figures of tests with over 28.4 per cent ash, which is rather a low percentage as compared with chain-grate practice with western fuels.

As to flexibility with pulverized coal, the writer has seen cases where the furnace became unresponsive when forced. There is certainly no evidence in the paper to indicate that the pulverized-fuel burner is quickly responsive over a wide range of loads; in fact, the evidence is much to the contrary, for of all the tests referred to, the maximum overload indicated is 188 per cent, which is not considered a high overload in modern specifications and practice.

Furnace Design. Under this heading the tests of Table 2 are referred to. Tests of four or five hours' duration should not be included in an A. S. M. E. paper. Efficiencies of 70 to 80 per cent are shown here. Starting and stopping conditions, surging of water in the boiler and other items are so uncertain as to make these short tests absolutely unreliable. Under similar conditions, tests of 100 per cent efficiency and even higher are frequently made.

To be more specific, the writer would inquire if in the test of April 16, 1917, at Seattle, the heating value of the coal was determined by a calorimeter or was it assumed. The even figure of 10,000 simply suggests estimated figures.

What great difference brought about the marked increase in efficiency between the December 4 and December 12, 1917, tests at Chanute, Kan.? This wide difference is inconsistent with the statement of uniform efficiencies, regardless of operatives, coal or other items.

On the January 28, 1918, test at Chanute, Kan., of 25 days' duration, were the water and coal weighed? Did the boiler operate this long without the blow-off being opened, or if the boiler was blown down, how was the blow-off discharge measured?

Tests of April 26 and 28 at Parsons, Kan. Some tests were made at this plant simply by measuring the coal in a spiral conveyor. Was this done in this instance or were the coal and water properly weighed? The writer has a record of other tests made at this plant, as follows:

Horsepower Developed	Combined Boiler and Furnace Efficiency Per cent.
186	53.9
194	73.5
230	67.8
247	67.4
506	61
356	59.0
230.5	71.5

These results indicate the possibility of low efficiencies on tests with pulverized fuel. What, then, may we expect in daily operation? Why should we pick only favorable tests for comparative figures?

On the test of April 26, should not the percentage of rating be given?

The writer is surprised at the high calorific value of the slush anthracite in all tests reported, as it has the highest heat value of any coal in the tabulation. We should not confuse this with low-grade anthracite, which contains less than 9000 B.t.u. The fuel mentioned in the test of December 2, 1918, is evidently incorrect, as it is difficult to imagine a coal containing 23.92 per cent ash and 15,420 B.t.u. This discrepancy is concurrent with the highest-rating test recorded, casting more or less doubt on the entire test.

The complete data of temperatures, draft and CO_2, together with methods of measuring fuel and water, should be given for these tests.

Referring to the statement that a modern stoker-fired power plant with the best average plant operation obtains an efficiency of not better than 63 to 65 per cent, while carefully conducted tests show 75 per cent efficiency, the writer suggests that the authority for this statement be mentioned so that full credit can be given. This may be true with some types of stokers not completely automatic but dependent largely on the firemen's skill. With the chain-grate type, however, it is far from true, in fact the chain-grate plant operates within 2 or 3 per cent of the test figures, and test figures with modern chain-grate furnaces run frequently in excess of 75 per cent net efficiency. It has always been a feature of chain-grate performance that daily operating results approach very closely to maximum test efficiencies with no deductions to be made for fans or other auxiliaries. The fuel costs for modern chain-grate power stations may be adduced to confirm this fact.

The authors have selected for their comparison those types of stokers with which it is most difficult to get high operating efficiencies, whereas if the comparison were made with completely automatic stokers such as chain grates, the statement made of the operating advantage becomes void, as chain grates are evidently more capable of reproducing test results in daily operation than the pulverized fuel furnace.

Cost of Pulverizing Coal. Under the item of Drier Fuel the writer notes that all costs are based on only 7 per cent moisture and yet many of the fuels mentioned in the tests contain more than 7 per cent. Comparatively few fuels have as low as 7 per cent moisture, particularly west of Pittsburgh. The figures run from 10 to 40 per cent in the western section of the country, figures of 15 per cent predominating. The writer suggests therefore that the drying coal cost should be doubled.

Interest. As mentioned earlier, the pulverizing equipment should be duplicated to prevent shutdowns, which would, of course, raise the equipment's interest charge. There are some uncertainties regarding the cost of this equipment, as some of the plants mentioned are reported to have cost several times the figures quoted in the paper. The writer would therefore safeguard this figure by making it at least three times that used by the authors.

Depreciation. In figuring depreciation, everything should be limited to 10 years, inasmuch as we have all seen three or four complete changes in power-plant equipment in the last 30 years and are likely to see the same in the next 30 years. To figure that the fuel-pulverizing building has a useful life of 40 years is making a pretty strong effort to show up pulverized fuel in a favorable light.

The writer would therefore recalculate Table 1 as given on the following page.

Cost of Stoker Operation. In making this comparison, the authors have again selected those types of stokers which show highest operating costs and cause the pulverized-fuel installation to benefit by contrast.

The power to drive some types of stokers may be as high as 2 per cent. Chain grates require but 1/10 of 1 per cent. Power for fans with those types of stokers requiring fans may be 2 per cent of the power developed. Chain grates have no fans, so this item is eliminated. Coal handling would seem to be an item which would cancel out, as it should cost no more to deliver coal to the stoker hoppers than to the pulverizer. However, accepting these

TABLE 1 COST OF DELIVERING PULVERIZED FUEL TO BOILER

	100-ton plant, dollars per net ton	1,000-ton plant, dollars per net ton
Power at 3/4 cent per kw-hr. and 17 kw-hr. per ton..	0.1275	0.1275
Labor at 50 cents per hour (40 cents too low).....	0.175	0.05
Drier coal at $5 ton delivered (15% H_2O)	0.12	0.12
Repairs (no data—accept authors')..........	0.07	0.07
Total cost of pulverizing per net ton[1]	$0.4925	$0.3675
Interest at 6 per cent. (Triple the investment)....	0.315	0.117
Depreciation (10-yr. basis): Multiply authors' figures by 3....................	0.36	0.12
Taxes and insurance (no data—accept authors' figures)............................	0.035	0.013
	$1.2025	$0.6175

[1]In existing plants of 500 to 600 tons daily capacity this figure is reported to actually be $1 or more per ton, indicating that in actual practice and operation many incidental items of cost enter which are not shown in a theoretical estimate.

figures on the authors' basis, we have as follows per 1000 tons of coal:

Power for stokers, 1 hp. per 1000 developed; chain-grate practice, 20 cents per 1000 lb. of steam.......	$ 4.00
Power for fans, standard chain-grate practice........	0.0
Coal-handling power (accept authors' figures)......	18.00
Labor for coal handling (accept authors' figures)....	19.20
Repairs for stokers (accept authors' figures)........	17.50
Repairs for coal-handling equipment (accept authors' figures)	10.00
	$68.70
Total cost per net ton..........$0.0687	

We have, therefore, an additional cost of from 55 cents to $1.13 per ton against the pulverized-fuel plant, a figure that cannot be made up by increased efficiency, for it must be realized that many stoker installations have given performances within 5 per cent of the highest theoretically possible.

Now as to some of the items not mentioned by Messrs, Scheffler and Barnhurst in their paper.

Fine Ash. The writer understands that from 60 to 80 per cent of the ash carries over to lodge in tubes and combustion chambers, but mostly goes out of the chimney to scatter over the surrounding country. This may by comparison not be objectionable in a cement mill or in some of the localities mentioned in the list of installations, but it is evident that if the Commonwealth Edison Company of Chicago were to scatter fine ash from the 5000 or more tons of coal they burn daily, say 600 to 800 tons of ash, it would create a condition compared to which the worst smoke fog would seem like a paradise.

Slag. Some installations have encountered trouble due to the fine ash slagging in the tubes. The writer would inquire how prevalent this is, how it is overcome or prevented and what influence high boiler ratings seem to exert on it.

The refuse from pulverized-fuel firing contains some combustible. It has been reported that the slag containing this combustible causes damage to ashpits. Is this a serious item of maintenance?

It is reported that pulverized fuel if stored will pack and become difficult to handle. Where the container is jarred or vibrated this action is reported to increase. How serious is this action? Does it interfere with the use of stored powdered coal? Does it preclude its use on shipboard?

Turning now to Mr. Harrison's paper, the coals he states as most suitable seem to have (*a*) less than 10 per cent ash, (*b*) volatile 30 to 40 per cent, (*c*) low sulphur, and (*d*) high melting point of ash. This, of course, means a very choice bituminous coal. Such fuel commands a high price in any market, much higher per 1000 B.t.u. than the high-sulphur, high-ash fuels frequently competing. For instance, there are in Illinois and Indiana coals containing 18 to 20 per cent ash, 3 per cent volatile, 6 to 8 per cent sulphur, with the fusion point of ash at 1900 deg. The writer would inquire as to whether in the present state of the art this fuel could be commercially used to develop, say, 150 per cent rating from a boiler by means of pulverization.

It seems to be a prevalent opinion that lignites cannot be burned on stokers. The writer would rectify this at once. Lignites and sub-bituminous coals are being burned and producing high efficiencies and capacities. The following results of a few tests will substantiate this statement:

Fuel..........................	Colo. Lig.	Tex. Lig.	Mont. Sub-Bit.	Mont. Sub-Bit.	Mont. Sub-Bit.	Mont. Sub-Bit.
Moisture, per cent........	23.73	29.93	20.73	15.28	15.27	20.52
Volatile, per cent	35.25	30.96	33.44	37.56	41.24	31.23
Fixed carbon, per cent..........	33.23	25.45	32.50	38.07	30.91	39.00
Ash, per cent..................	7.79	11.66	13.28	15.09	12.58	9.25
B. t. u. (comm.).............	8511	7124	8772	9118	9553	9096
B. t. u. (dry)................	11116	10314	11073	10763	11275	11444
Type of stoker................	Green	Green	Green	Green	Green	Green
Type of boiler................	B & W	B & W	B & W	B & W	B & W	B & W
Coal per sq. ft. per hr., lb.......	28	32	28.91	38.06	30.46	35.31
Furnace draft, in..........	0.232	0.32	0.167	0.221	0.17	0.196
CO_2 at damper, per cent	12	11.81	10.36	12.97	11.77	12.62
Per cent. rating developed.....	128	....	145.8	209.1	181.5	195.09
Combined efficiency, per cent	69.7	69	72	75.6	77.3	78.04

The ability to burn these coals is a development of the last few years, and has opened up a wonderful fuel field to chain grates. Some of these fuels contain as high as 30 per cent moisture, in which case the drying cost when pulverized fuel is used would be 4 2/7 times those given in Table 1 and would make it necessary for the pulverized-fuel installation to obtain somewhere in the neighborhood of 100 per cent efficiency to be on a competitive basis.

Moreover, these fuels do not at this time command a price anywhere near $5 per ton, so that the cost of drying and pulverizing represents probably about 25 per cent of the fuel cost, a figure not to be regained by increased efficiency.

Reference is made to the use of low-grade refuse around the mines, as at Lykens, Pa. Mr. Sheffler and Mr. Barnhurst also refer to this same fact in their paper. The coals they mention, however, have calorific values not only far beyond the average idea of culm piles (12,500 to 15,400 B.t.u.), but are good enough to be used to advertise the coal. Certainly no western fuels and few mid-western fuels will equal these supposedly refuse coals.

It should be understood that when a chain-grate engineer refers to low-grade coal, he certainly has in mind fuel containing less than 9000 B.t.u., dry basis. No such fuels seem to be discussed even as refuse fuels in pulverized-fuel practice.

Mr. Harrison bases his costs of pulverizing on pre-war labor prices (30 cents per hour for millers, 20 cents for firemen and common labor), war coal prices (which is not consistent with 20-cent labor), and 7 per cent moisture in the fuel. His figures for labor should be doubled. For average fuels the moisture percentage should be doubled, and for the real field as mentioned by the author at least quadrupled for coal with 30 to 35 per cent moisture.

Referring now to (*a*) under Pulverized Coal vs. Stokers, the writer would inquire if a furnace suitable for lignite will handle anthracite. High overloads are spoken of freely and he would also inquire just what ratings have been sustained or even reached to confirm this.

Stokers are criticised in (*c*) as requiring more area for high overloads than pulverized-fuel burners. Has this been proved to be commercially true? With chain grates and coals such as mentioned in the average pulverized-fuel test, ratings of over 250 per cent are sustained for long periods, and peaks swung for short periods beyond this rating. Have any pulverized-fuel installations so far equaled this?

Referring to (*e*), the writer would state that not only is ash more easy to handle, but there is only about one-fourth of the usual amount, the remainder going out the chimney. This is one item of decreased cost that pulverized-fuel exponents seem loath to claim. We certainly must overcome this difficulty if we are to make pulverized-coal plants commercially successful, as our city and health ordinances will soon put the ban on this wide distribution of fine ash.

The writer would correct item (*f*) to say that coal burned on stokers may contain from 1 to 35 per cent of free moisture as fired. As a point of interest, he would inquire as to how readily pulverized coal picks up moisture when stored.

Under (*d*) in the following paragraph certain changes in the furnace are mentioned to suit various coals, also rather extensive changes in drying equipment. This is contrasted with stoker practice. The author presents as a favorable argument for pulverized-fuel burners that, with only a slight change in the furnace and some increased drying capacity, the equipment may be changed from one suitable for anthracite to one suitable for lignite. The writer would inquire in what commercial fuel market or location is this a valid benefit. What market receives both anthracite and lignite as steam coals?

Referring to the comparison of costs given under the heading Pulverized Fuel vs. Mechanical Stokers, the writer would question the estimated figure of 32 cents and would state that since the installation had its acceptance test ten months ago, the costs should not be concealed, but should be made part of the paper.

Reference to Table 1 in the complete paper would indicate that pulverizing cost would be

(*a*) For pulverizing and drying 12 per cent moisture coal	\$0.516
(*b*) Labor (use 2 times tabulated cost)	0.08
	\$0.596
Maintenance (use author's estimate)	0.03
	\$0.626

As a matter of fact, in existing installations of from 500 to 600 tons daily capacity, the cost of drying and pulverizing fuel is over \$1 per ton. This makes pulverized fuel prohibitive for steam-making purposes.

From all the figures presented, some good efficiencies are indicated when high-grade coals are burned (no tests are presented on low-grade coals). The advantage in efficiency, however, is insufficient to offset the increased cost of preparing the fuel, even on a basis of \$5 fuel. This causes the pulverized-fuel burner to operate at a loss, regardless of the efficiency obtained. Fuel costs will have to be from 50 to 100 per cent higher before the increased cost of pulverizing will be justified, unless pulverizing and drying costs decrease materially.

Further, no modern ratings are recorded in the paper; furnace and slag troubles are minimized; quick pickups of boiler load over a wide range of rating are not proved and seem very problematic; ash from chimneys is at present a prohibitive feature in cities.

FRED'K A. SCHEFFLER (written). I cannot agree with Mr. Harrison in his statement that when a boiler is being run with pulverized coal it is not necessary to have more than 0.10 to 0.15 in. draft at the damper of the boiler, and consequently the boiler could be operated with stacks about 30 to 35 ft. in height. It is a well-known fact that it is necessary to have at least 0.10 in. in the furnace, and that the average water-tube boilers have a frictional or draft loss through the boiler of about 0.30 in. when run at rating, and when run at 200 per cent of rating this draft loss is almost double, or 0.60 in. Consequently, the stack would have to be at least 125 ft. in height in order to be sure that there is sufficient draft to overcome the frictional resistance through the boiler and allow a suction of at least 0.10 in. in the furnace.

W. N. BEST[1] (written). I should like to inquire how many open-hearth furnaces there are in the U. S. that are successfully burning pulverized coal, and for how long a period they have been operated.

The Boiler Test Code Committee of the A.S.M.E. would like to know of large power plants that are and have been successfully burning pulverized coal for a period of, say, 4 years. We have endeavored to locate such plants for some time in order to examine same and secure some data for the Society. I am aware that many plants have experimented with pulverized coal in the generating of steam, but results were very disappointing.

[1] Pres., W. N. Best, Inc., New York City.

At the beginning of Mr. Harrison's paper, he states: " . . . and the shortage in the supply of crude oils which have become of too great value for ordinary fuel purposes." This, I think, is misleading, for statistics prove that the production of oil has never before been so great, and the demands for it never so great, as today. In Mexico alone there are many reservoirs as large as lakes filled with crude oil awaiting transportation, and hundreds of wells are capped awaiting to be turned on to meet the demand.

The increased price of coal and the liability of further increases in its price have compelled many boiler plants along the Eastern Coast to change to oil as fuel, and many more contemplate changing soon. The cost of oil is now very attractive in boiler plants owing to the fact that it only requires 147 gal. of oil to represent a long ton (2240 lb.) of bituminous coal, the coal having a calorific value of 14,000 B.t.u. per lb. One man can fire and water-tend twelve 300-hp. boilers. Oil is so attractive at the present time as a fuel along the Atlantic Coast that I believe it will only be a matter of a year or a year and a half until all the larger power plants will use Mexican oil as a fuel in their boilers.

It is my opinion from close observation and study that the two distinct fields for pulverized coal are the furnaces of rotary kilns and copper matting furnaces. Both of these are constructed so that the building is quite open, and there is practically no liability of explosions being caused by spontaneous combustion. I believe the large quantities of poor coal and lignite that we have in our country can be successfully burned in combination with oil, the coal and lignite referred to being, of course, in the pulverized state. By this combination practically perfect combustion can be attained and maintained at all times, and this combination could be of value owing to the low calorific value of the coal and lignite, and the high calorific value of the oil. The process of burning this combination of fuels would not be by mixing them together, but each fuel should be delivered separately to the furnace.

W. G. DIMAN[1] (written). So far as the better grades of bituminous coals are concerned, I think that the cost of drying, pulverizing, conveying, feeding and the first cost of the apparatus, together with the fact that all grades of fuel can be burned with a tolerable degree of smokelessness and efficiency in the regular stoker apparatus, will restrict the use of pulverized coal for boiler purposes to special cases. If low-grade waste coal can be utilized for pulverized fuel there is a great field for its use. There must be some limit, however, in the use of low-grade fuel, for the cost of grinding would eat up any advantage in the economy. Where low-grade fuels are high in ash and slate there should be a limit to the proportion that one can afford to grind. The use of high-ash coal will be bad, as it will accumulate rapidly and be difficult to remove, especially if it slags to any extent. This would occur more where the ash deposits are within the limit of the flame. With anthracite, especially culm and of that nature, it might be difficult to pulverize and must be finely pulverized; it needs a higher temperature for combustion, burns more slowly, and in certain boilers like a H. R. T. it would require plenty of brickwork and a large combustion chamber to avoid the chilling effect and to maintain combustion. The best coal to use is one high in volatile and low in ash. Such a coal would not be a very satisfactory one for outside storage in large quantities due to the likelihood of spontaneous combustion. In order to successfully use the pulverized fuel, I am of the opinion that the best results can be obtained by designing the furnace and equipment to meet a specific grade of fuel. I do not think that the average cost per ton for getting the coal from the car into the boiler is as low as stated, and if the overhead is also taken into consideration it will run still higher.

E. H. PEABODY[2] (written). In Mr. Harrison's paper I note that among other important matters he mentions three points which occur to me as particularly significant in the use of pulverized coal for boiler purposes:

[1] Supt. of Power, Amoskeag Mfg. Co., Manchester, N. H. Mem.Am.Soc.M.E.
[2] Marine Dept., The Babcock & Wilson Co., New York City.

1 Very large furnace volume required, or, in other words, the fuel must be burned under conditions which imply a very low rate of combustion per cubic foot of furnace volume;
2 The continual effort necessary to keep the boiler tubes, and, to a less degree, the furnace itself, free from slag and clinker caused by the refuse in the coal; and
3 The very high, and apparently inaccurate, boiler efficiency reported in the tests of August 12-13, 1918, which appears to be due to crediting the boiler with work done by the coal driers.

If, as seems to me proper, the boiler efficiency is figured on the basis of the heat value of the dry fuel, the result should be 76.3 instead of 85.2. The degree of efficiency obtained in the drier itself would in no way affect the results obtained in the boiler in actually transferring the heat in the fuel to the steam.

Oil fuel is undoubtedly superior to all others for boiler purposes. The furnace volume required for this fuel to give satisfactory results is about one-quarter the furnace volume specified in the paper for pulverized coal.

The similarity of action in many features between oil fuel and pulverized coal appears to me to constitute one of the principal attractions of the latter. It would seem, however, that the large furnace, with its extra first cost and extra radiation loss, together with the difficulties due to slag and their effect on operation, would offset the desirability of pulverized coal to a very large extent.

Albert A. Cary[1] (written). To many who have not had occasion to keep informed concerning the previous use and past applications of powdered coal as a fuel, the idea seems to be prevalent that such fuel is a recent development, holding almost unlimited possibilities for all kinds of furnace applications and capable of easily and cheaply accomplishing phenomenal results.

As a matter of fact, inventors have been struggling for almost a century to make powdered coal a practical and successful fuel.

In 1831 an English patent was issued to J. S. Daws for a process for burning powdered coal, and this was rapidly followed by a large number of patents relating to this subject in England, the United States, Germany and elsewhere.

In 1881 a United States patent was issued to C. H. Palmer describing the means for feeding fine coal to a locomotive boiler with an air blast, while in 1870 Whelpley & Storer began to take out a series of patents for using pulverized coal in reverberatory metallurgical furnaces. In 1876 an elaborate series of tests was conducted by the Bureau of Steam Engineering of the Navy Department under the direction of B. W. Isherwood—using the Whelpley & Storer pulverized-coal system applied to a steam boiler.

Thus we are able to understand that the preparation and use of pulverized coal fuel is by no means a recent development, and notwithstanding the considerable expenditure of money, effort and ingenuity by many inventors, including men whose past experiences qualified them to carry on such work; most of these older productions have been scrapped so that today we have left merely the benefit of their varied experiences, which has, nevertheless, proved a valuable source of information for the more recent developments in the preparation and use of pulverized coal.

Turning now from this record to the more recent developments, it will require but little investigation to find that during the last decade (or even for a much shorter period) there have been many powdered-coal installations which have either been rejected or found to give poor satisfaction.

After the presentation of such facts, I may be accused of condemning the use of pulverized fuel as a practical and efficient fuel.

On the contrary, in the light of my experience and with the evidence presented by many satisfactory equipments now in operation, I am an unqualified advocate of the use of such fuel, but I must limit my endorsement to applications where a desirable grade of fuel is available—where proper preparation of the fuel and proper furnace conditions can be obtained and where other methods for burning the available fuel are inferior—to accomplish the desired heating.

About 24 years ago I was called upon to assist in the development of a pulverized coal equipment for a cement plant, and since that time I have been called upon to test, investigate and design a number of pulverized coal equipments for cement kilns, boilers, metallurgical and other industrial furnaces and thus have had an opportunity to follow the development of this art since the early days of its practical commercial adoption in this country.

[1] Consulting M. E., New York City.

Pulverized Coal in Cement Plants

Mr. Harrison has very properly given first place in his paper to the use of pulverized-coal fuel in the rotary kilns of our cement plants, as not only do we owe the present development of our pulverized-coal equipments to the pioneer work done in their development at such plants, but the very form of these long, cylindrical, refractory-lined furnaces furnishes us with the ideal construction for the use of this form and kind of fuel.

They permit the use of the long, air-projected current of finely powdered fuel, giving it ample time to complete its combustion while being held in suspension and without direct flame and ash impingement upon any impeding furnace wall.

The simplest form of burner and fuel-feeding device can be used with such furnaces, and the ash resulting from the combustion of this finely ground coal causes little or no trouble, providing the ash content and its quality remains nearly constant, as this ash drops down and mingles with the burned clinker without materially affecting the quality of the final product.

Pulverized Coal in Metallurgical Furnaces

Next in order of desirability in the way of furnace design for the use of pulverized coal, we have our reverberatory metallurgical furnaces of great length (100 to 150 ft.), such as are used for copper smelting, where the flame is projected from the front toward the rear of these furnaces over the charge of ore on the hearth.

Without the exceptional facilities for taking care of the ash resulting from the combustion of the pulverized coal as found in the rotary cement kilns, ash troubles proved to be a pretty serious matter with the early pulverized-coal installations applied to these furnaces about a dozen years ago.

The ash fused and formed a slag blanket over the top of the ore charge and stuck to the interior of the flue outlets in a way to block these passages; but these and other associated troubles were finally overcome by stopping the infiltration of large amounts of cold air, by stopping the practice of charging large quantities of cold ore into the furnace, by using a better design of burner and coal-feeding device, and by a more careful preparation of the pulverized coal.

By these means a much higher temperature was maintained in the furnace, a very much higher ratio of charge to fuel used was obtained, and a better and more constant regulation was secured at the burner. Then pulverized coal began to be recognized as a most excellent reverberatory fuel.

When pulverized coal was used as a fuel for shorter and smaller reverberatory furnaces and directly fired into their interiors, the above-named troubles were accentuated and due to the imperfect absorption of the heat in these furnaces, the use of waste-heat boilers generally became a necessity in order to obtain efficient results. Accumulations of more or less fused ash piled up rapidly on the heating surface of these boilers necessitating frequent cleanings. Experience has shown that the reversing type of furnace for the production of open-hearth steel, such as described in Mr. Harrison's paper, is the best design of pulverized-coal furnace for that purpose. Checkerwork and baffle walls must be specially designed for use of this fuel.

A modification of the above-described reverberatory furnace, consisting of an extension furnace in front of the main furnace chamber, so proportioned as to retain a large percentage of the ash within this chamber, makes a highly efficient equipment. It requires a burner equipment permitting a close regulation of its

coal and air supply, and one which will produce a short, brush-like flame close up to the burner, which means a very rapid combustion and a high temperature in the combustion chamber.

In some recently-built extension furnaces a large percentage of the ash is separated from the body of the flame and drops into a comparatively cool part of the chamber as a fine, dry ash mingled with but a small percentage of fused ash nodules, which do not interfere with the easy removal of the refuse from the furnace bottom.

With other recent designs of extension furnaces, where very high temperatures are maintained at the burner outlet, the rapid fusing of the ash is expedited, which refuse drops to the slag pit below in a molten mass and under proper conditions may be drawn off through tap holes from the bottom of the extension furnace.

Such a design of extension furnace has been installed by the Lopulco Company in a steel plant near Pittsburgh, in connection with their heating furnaces, where it has given excellent satisfaction.

Application to Stationary Boiler Plants

The application of pulverized-coal fuel to steam boiler furnaces meets with many challenging difficulties, which, however, recent developments have done much to overcome. A number of such installations are in use, some of which are showing very desirable economy and producing a material increase in the steaming capacity of the boilers.

Great care must be taken to prevent any of the unconsumed coal from coming in contact with the chilling water-containing surfaces of the boiler, which, therefore, demands the use of an extension furnace in which the complete combustion of the coal is accomplished, and in which the proper handling of the fine ash (and its resulting slag) is provided for.

All that has previously been said concerning the requirements needed for extension furnaces applied to short reverberatory furnaces apply with equal force here.

With the intense heat generated in burning pulverized coal, much trouble has been experienced in improperly designed boiler furnaces due to the rapid melting down of the refractory linings, which may also be subjected to the scouring or cutting action of impinging ash, thus requiring frequent and expensive relining.

Process of Combustion of Pulverized Coal

Pulverized coal *must* be burned while suspended in the current of air which accompanies it into the furnace.

As the finely divided coal enters the highly-heated furnace, any moisture contained by each minute particle is first driven out, and if this is excessive, it will form a steam cloud around the particle and suppress its further rapid combustion, thus defeating to a greater or less extent the purpose for which the coal was prepared.

One of the necessities for supplying the furnace with very dry pulverized coal is thus appreciated.

With little or no moisture present, the next effect of the very high surrounding temperature in the furnace is to almost instantly distill off the volatile matter occluded in the coal as this gas is liberated at a comparatively low temperature and thus, with properly designed furnace and burner, the dust cloud entering the combustion chamber suddenly becomes thoroughly saturated with a highly inflammable gas, mixed with an ample supply of air.

Under these conditions the gas is raised to its ignition temperature with great rapidity, and the flame produced is propagated with intense speed throughout the atmosphere of fuel and air entering the furnace; all of which is simultaneously subjected to the same action.

With the intense degree of heat thus generated, not only is the temperature of the furnace maintained to stimulate further combustion, but the particles of fixed carbon (or flecks of coke) left behind, after the volatile gases have been driven out of the coal, have their temperature raised with great rapidity to their temperature of ignition and so are most speedily burned leaving behind the non-combustible matter (which we have called ash) to be more or less effectively taken care of in a properly designed furnace, or to give great trouble in furnaces where its importance has been ignored.

Mr. Harrison very tritely states that "The *finer* the coal is pulverized, the more efficiently it can be burned."

With the above analysis of the process of combustion before us, we can more readily understand the reason for this statement. Not only does the greatly increased fuel surface (presented to the highly heated interior of the furnace) facilitate the more rapid distilling off of the volatile gases, but with the volume of the particle itself greatly reduced, the penetration of the heat to its interior takes place in a very much shorter period of time. Aside from these advantages the important fact stands out that the Law of Mass Action applies to such combustion (which is akin to the action of explosives) by which we find that the amount of the reaction in a unit of time is proportional to the active mass, or, in other words, the smaller the particle of coal, the smaller the number of gram molecules of combustible matter found in the unit mass.

Under these most favorable conditions, the velocity of combustion is greatly accelerated, which is the principal object striven for when pulverized coal is chosen for a fuel.

A moment's thought will recall the fact that the volume of a mass varies as the cube of its diameter and thus a particle of coal 1/100 in. in diameter has eight times the volume that is found in another particle that is 1/200 in. in diameter.

The effect of the decreased surface in proportion to the mass results in a very great retardation of the combustion of the larger particles as is very plainly shown in the photographic study of the combustion of coal dust in Bulletin No. 102 of the Bureau of Mines, entitled The Inflammability of Illinois Coal Dusts on Plate IV. B and Plate V. B.

Uniformity in the size of pulverized particles is also very desirable, as we can readily understand that if we have mixed a considerable percentage of each of the above named sizes of coal fed to our furnace, the combustion of the larger size will proceed much slower than the burning of the smaller size, which condition not only reduces the velocity of combustion of the total mass, but it prevents the production of that "gas-like flame," which Mr. Harrison refers to.

When such grades of coal, averaging from 30 to 40 per cent of volatile matter, as described above, are pulverized so that over 90 per cent will pass through a 200 mesh screen, the finer coal accompanying it does not seem to materially affect its even rapid burning effect in general furnace practice; and further, as Mr. Harrison has stated, with this very fine pulverization, which insures rapid and high temperature combustion, the sulphur in the coal burns rapidly to SO_2 gas, which passes to the stack without affecting the product of the reverberatory furnace.

When a coal, running high in fixed carbon, is used as pulverized fuel, we have a different and less desirable set of furnace conditions.

Lacking the production of an ample supply of volatile combustible gases given off by the coal at a comparatively low temperature, and also lacking the heating effect which the burning of these gases produces, to hasten the combustion of the associated fixed carbon, we must necessarily maintain a higher furnace temperature to ignite this fuel, and to obtain the best possible results, the coal should be ground finer, as it will be found that this fuel is slower to ignite. Much of such coal carries a higher ash content, which still further complicates matters and lowers the heat value of the coal.

Mr. Harrison gives a table purporting to give the cost of coal pulverized-coal system upon which these figures are based nor question the reliability of these figures. Nothing is said of the pulverized-coal system upon which these figures are based nor the class of machinery or equipment included.

There is a considerable range in cost of equipments as furnished by different concerns and the figures presented in this table appear low for the better class of equipment.

Much depends upon the class of equipment one is willing to in-

stall, which has much to do with results obtained including cost of future upkeep.

There are many elements entering into the cost of such equipments. For example: should one be obliged to handle very wet coal in the coal dryers, the normal capacity of the drier would be reduced and either larger driers or more driers would be required to obtain a fixed amount of dried coal, which would also require a greater building space.

Again, should one decide to grind the coal very fine to obtain maximum furnace results, the output capacity of the pulverizer would be materially reduced below that needed for coarser pulverization and more or larger mills would be needed, and thus I might continue this list.

Whereas, Mr. Harrison's total cost for pulverizing 80 and 90 tons of coal per day agrees pretty well with the cost estimate given in this table, his cost for producing 100 tons per day runs 21 per cent higher than the figure shown in the table.

In looking over the log of the boiler test quoted by Mr. Harrison I note what appear to be a few discrepancies, but lacking full and complete data, I have been unable to check them up as carefully as I would otherwise do.

Taking his analysis of furnace gases, he gives the maximum result obtained as 15.4 per cent of CO_2 and 5.6 per cent of C with no CO.

This is consistent and possible.

He then gives his minimum result obtained as 12.2 per cent of CO_2 and 3.2 per cent of O with no CO; the sum of these gases giving 15.4 per cent with 84.6 per cent of N by difference.

There is evidently some discrepancy here, as I do not see how it is possible to burn such a coal as he indicates so as to obtain such an analysis.

The percentage of boiler efficiency given in this table as 85.22 per cent seems entirely inconsistent and I cannot find sufficient indication contained in the other data submitted to assure me that the total losses in the performance of this test amounted to only 14.78 per cent.

One very interesting question in connection with this test is, What means were used for accurately weighing the pulverized coal used? As a matter of secondary importance I might also ask, What means were used for ascertaining the weight of water fed to the boiler?

J. E. Muhlfeld[1] (written). Mr. Harrison's excellent paper reviews data that conform in general to my experience during the past few years in the development of systems for the more effective and economical utilization of coals and lignites in pulverized form, for stationary, locomotive and marine boilers, and for metallurgical and chemical heating furnaces, and the information that he has given will be of great assistance to existing and prospective users of this method of firing and burning solid fuels.

Until recently power-plant capacity and efficiency have been dependent upon combustion possibilities. Fortunately, this has now changed and the problem is in boiler design and construction.

In the log of test on a pulverized-fuel-burning stationary boiler given by Mr. Harrison, the operating capacity deductions on account of the power and other items necessary for the preparation of the coal in pulverized form should be 3.17 per cent, in place of 4.22 per cent, as used in arriving at the net efficiency. This figure of 3.17 per cent compares with the power necessary to operate mechanical stokers, and which, in an installation of this kind, would amount to from 2½ to 5 per cent, varying with the boiler load carried.

In connection with this log of test data it may be of interest to give the heat balance for the same 24-hour run, which is as given in Table 2.

Furthermore, to show the definite control over stand-by losses by the use of the same pulverized-fuel system, at the same plant, the data in Table 3 are of interest.

To further show the positive control over the combustion, the performance of one of these boilers in Table 4 is of interest. During the 14-hour run, from 6 p. m., February 1, to 10 a. m., February 2, for which period the boiler was sealed and operated at about 150 per cent rating, it will be noted that there was a change of only 0.2 per cent in CO_2 and 0.4 per cent in O_2, and no slag was produced.

Observations made of the stack from the outside of the power-plant building, when operating the pulverized-fuel and the stoker-equipped boilers in combination and independently have also demonstrated that no smoke was produced from the pulverized-fuel-fired boilers.

The four pulverized-fuel-equipped boilers at this plant were cut in on the main line over 90 per cent of the time during the months of February and March, 1919, and when line banked no fuel was required.

Referring to various information as set forth in Mr. Harrison's paper, I would like to point out the following:

I can hardly agree with Mr. Harrison that the equipment for

TABLE 2 HEAT BALANCE FOR BOILER TEST IN TABLE 3 OF MR. HARRISON'S PAPER

Ultimate analysis of pulverized Indiana and Illinois screenings as fired, given in percentages;

1	Moisture	3.20
2	Carbon	55.66
3	Hydrogen	4.47
4	Oxygen	19.77
5	Sulphur	1.97
6	Nitrogen	1.45
7	Ash	13.48
		100.00

The distribution of the calorific value of one pound of coal as fired among the several items of heat utilized and lost is as follows;

	B.t.u.	Per cent.
Heat absorbed by boiler	9,934	85.22
Loss due to evaporation by moisture in coal	41	0.35
Loss due to heat carried away by steam formed by burning of hydrogen	493	4.22
Loss due to heat carried away in dry flue gases	975	8.37
Loss due to carbon monoxide	0	0.00
Loss due to combustible in ash and refuse	51	0.44
Losses due to heating moisture, in consumed hydrogen, hydrocarbon, radiation and unaccounted for	163	1.40
Calorific value of fuel as fired	11,657	100.00

TABLE 3 SHOWING CONTROL OVER STAND-BY LOSS

Date	August 18-19, 1918
Boiler No. 5	Edge Moor, Rated 468 nominal hp.
Fuel feed shut off, uptake damper closed and auxiliary air inlets closed	9.00 p.m.
Boiler steam outlet to header closed and 175 lb. steam on boiler	9.20 p.m.
Safety valves released about one minute at the following times (p.m.). 9.40, 9.55, 10.08, 10.15, 10.25, 10.38, 10.43, 10.52, 11.02, 11.09, 11.18, 11.28, 11.38, 11.48, 11.52.	
Steam on boiler 155 lb. when fuel feed started and boiler steam outlet to header opened	7.00 a.m.
Drop of steam pressure in boiler, from 9 p.m. until 7 a.m., or during 10 hours while fuel feed was off and during which time safety valves popped 15 times, for one minute each, or a total of about 15 minutes	20 lb.
Time required to bring boiler from 155 to 175 lb.	4 minutes

TABLE 4 SHOWING POSITIVE CONTROL OVER COMBUSTION

preparing pulverized coal has been developed past the experimental stage. There is still considerable to be done in this direction, particularly with respect to the elimination of the reabsorption of moisture and of entrained moisture, which results in condensation in the dry- or pulverized-fuel bins and the consequential trouble that it causes. The type and operation of drier and pulverizer has a great deal to do with these factors, and experience has demonstrated that certain fuels require special treatment in that regard or trouble is bound to occur.

From my experience, when pulverized fuel is used for steam generation the detrimental effect from the ash and sulphur content is nil, regardless as to the melting point of the former.

The economic use of coke breeze is at this time problematical, as the expense of preparing the fuel will, in a large number of cases, offset the fuel value of this by-product. A study should be made of each specific application before the use of coke breeze is gone into.

The utilization of the full thermal value of anthracite silt has been developed to a point where there are no commercial obstacles in its way, and this in itself will release an equivalent amount of commercial size of coal. The shipment of silt to a considerable distance from the mines, however, may not be economical, but the power consumption by the mining and nearby industries is sufficient for the full utilization of this by-product, which should make it unnecessary to ship the silt to other points.

The author's specific statement as to how the coal should be pulverized is not in conformity with my experience on this subject, as the degree of fineness should vary with the character of the fuel. The results of careful analyses and tests have demonstrated that this degree of fineness for effective and economical use cannot be arbitrarily set down, as it varies with the volatile content and the combustion characteristics of the fuel handled.

Commercially the expense of pulverizing increases with the degree of fineness, and consequently the coarser the particles of the fuel the less the cost chargeable against the pulverizing process, for which reason it is advantageous to use coarse pulverization whenever the character of the fuel is such that this is feasible.

From my experience the author's tabulated costs for pulverizing are somewhat misleading, as the cost for preparation will vary over wide ranges. While the information as set forth is valuable from a general standpoint, it must be used with care for the reason that it is not susceptible to specific adaptations.

In the case of open-hearth practice the system to be used for burning the pulverized fuel determines the degree of fineness. The high-velocity method of burning, such as described, will, of course, require much finer grinding than a low-velocity method such as obtains with other systems in which the time limit is increased, thereby permitting combustion to take place more slowly with the same thermal results.

By using a low-velocity flame the length of from 6 to 8 ft. mentioned by the author can be decreased.

Some of the steel companies have reduced their pulverized-coal consumption per ton of output to a little less than 450 lb. instead of 500 lb. as given in the paper.

It has been found in operating practice that pulverized-fuel-burning furnaces, under the best system of combustion, can be reduced to a little less than 1 cu. ft. of volume per b.hp. developed, and that the rating can be increased up to the capacity of the furnace to keep the lower tubes of the boiler free from honeycomb and still maintain effective combustion below the boiler-tube line.

The best system of combustion necessitates—

1 Proper preparation of the fuel
2 Effective means for feeding
3 Furnace properly designed and equipped with auxiliary air supply to insure a distinct hot zone and a distinct cold zone, and gas areas and baffles and draft coördinating with the foregoing.

The pressure at which pulverized fuel can be admitted to the furnace has been found, in service practice, to be not more than plus 0.05 in. of water at the burner nozzle.

In my opinion a boiler cannot be successfully operated at any capacity with the natural draft obtained with a 30- to 35-ft. stack, the reason being that the friction losses of the gases passing through the boiler tubes, and the gas areas produced by the baffles, will reduce the draft, due to this low height. When operating at full capacity about 0.10 in. of water draft in the furnace, plus the friction losses through the boiler setting, is the minimum under which any pulverized-fuel boiler installation should be operated. Anything less than this will limit the factor of regulation and will tend to cause constriction of heat to the furnace chamber and result in slag, which latter, in all cases, is to be avoided. Any pulverized-fuel-burning installation, in combination with a steam generator, in which the formation of slag is of any considerable consequence, can be taken as a failure from the standpoint of effective and economical results.

Under proper combustion conditions the use of a hand-lance steam jet to clean the bottom tubes as recommended by the author is unnecessary. The top of the tubes should, of course, be kept free from the accumulation of ash, which acts as an insulator and which tends to carry the heat in the ash and gases through the boiler to the stack.

While any ash accumulation in the bottom of the furnace should be periodically removed, at the same time with a proper design of hot-zone and cold-zone furnace any ordinary accumulation should not convert into slag.

In comparing pulverized equipment with stoker equipment, the author states that considerably less excess air is required with the former. The amount of air injected with the fuel into the furnace, however, should be a negligible percentage of that required for combustion, the only function of that air being a conveying and commingling medium. In the Edge Moor installation to which the author refers, the percentage of air entering with the fuel is about $1\frac{1}{2}$ per cent of that necessary for combustion, the remaining $98\frac{1}{2}$ per cent being induced by the stack.

[Mr. Muhlfeld supplemented the foregoing discussion and comment upon Mr. Harrison's paper with data upon performance of pulverized-fuel equipment in locomotive and marine practice, which constitute a most acceptable addition to his paper on Pulverized Fuel for Locomotives, given at the annual meeting, December 1916, and published in Vol. 38 of Transactions. Space does not permit the publication of these in this issue, but it is hoped to present them later.—Editor.]

Edwin Lundgren,[1] who opened the oral discussion, called attention to the large combustion space specified in Mr. Harrison's paper for a boiler burning pulverized fuel as compared to a stoker-fired boiler, especially when the boiler was to be operated at, say, 300 per cent of rating. In the matter of draft, he thought Mr. Harrison had not taken the resistance of the boiler into consideration in specifying but 0.10 to 0.15 in. For the ordinary type of boiler a draft of about 0.15 in. was required at 100 per cent rating, which increased to about 0.7 in. for 300 per cent. rating. A stack 100 ft. high would give about 0.6 in. draft, so that a height of 35 ft. was out of the question.

As to the low efficiency (63 to 65 per cent) of stoker-fired plants mentioned in the paper by Messrs. Scheffler and Barnhurst, he would cite the Detroit Edison plant where an average efficiency of 76 per cent was maintained throughout the year, and where Dr. Jacobus' series of 24-hour tests showed efficiencies of 80 per cent or better. Also, the Cincinnati Gas & Electric Co. maintained a combined boiler and furnace efficiency of about 80 per cent in their plant constructed to maintain 365 per cent maximum capacity and 300 per cent continuous capacity.

There was no question but what pulverized-fuel equipment would be useful in burning some of the cheaper grades of fuel, like some of the western fuels, for which it seemed no real type of stoker had been designed. He did not believe, however, that it would be generally applied to modern central stations, for one reason because the pulverized-fuel-equipment buildings, to judge from the slides shown, appeared to be about as large as power stations.

[1] Chief Engineer, Stoker Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

C. F. Hirshfeld[1] said that in modern boiler plants the chief losses were due to carbon in the ash and to heat escaping up the stack. The Detroit Edison Co. operated under good conditions with 10 per cent of carbon in the ash, or a very small per cent of the fuel originally fired, and with but 10 to 12 per cent of excess air. If use of powdered fuel would make it possible to burn all the carbon in the coal—which was contrary to his experience—and with no greater amount of excess air, the saving effected would still be of little consequence. He believed in using powdered coal where conditions were such that it was distinctly economical to do so, but these did not obtain at the Detroit plant. In his opinion there was a greater chance for improvement in the turbine end of the plant than in the boiler room.

As to greater uniformity of flame and temperature, which conduced to larger life of the furnace lining, he believed that the advantage was with the stoker with its smooth bed of incandescent fuel. While powdered fuel might be more adaptable when a wider range of fuels was available, the stoker was just as adaptable so far as the art had developed.

In the paper by Messrs. Scheffler and Barnhurst, the power for operating a stoker was stated to be 2 per cent of the total boiler hp. In the Detroit Edison Co.'s plant, however, it was much less than 1 per cent with the boilers operated at 200 per cent of rating.

H. Wade Hibbard[2] said that in a larger plant he had in mind an increased efficiency resulted from adding moisture to coal that had dried out too much before it reached the stokers. He therefore asked whether drying was necessary in order that the coal might be thoroughly pulverized, and also whether there had been any experiments performed in introducing steam along with the powdered coal. Affirmative replies were respectively made to these queries by Messrs. Scheffler and Barnhurst, the latter adding that he did not know whether the introduction of moisture had increased the efficiency.

P. A. Poppenhausen,[3] referring to a statement made by Mr. Lundgren, said that his company had successfully adapted the chain-grate stoker to the burning of lignites of all grades and containing as high as 30 per cent of moisture, and that 24-hour tests had shown efficiencies of from 76 to 78 per cent. The power to operate a stoker was insignificant—less than 0.5 hp. per unit, whether a 200-hp. or a 600-hp. unit. He thought Mr. Scheffler's figure of $64,000 low for the cost of a pulverizing plant of 100 tons daily capacity, and asked how large a plant should be in order that this cost would not be prohibitive.

John Van Brunt,[4] calling attention to Mr. Harrison's reference to coke breeze, said he could state that over 75,000 hp. of boilers equipped with traveling-grate stokers were now satisfactorily operating on this waste fuel in the large steel plants and gas works of the country.

Gilbert A. Young[5] spoke of successful experimental work carried on for the past two years at Purdue University on a furnace for burning crushed, undried coal containing as high as 20 per cent moisture. The particles after crushing ranged from the size of a match head down to powder passing a 200-mesh screen. He hoped to submit a paper later giving comparative tests of the crushed-coal furnace and several types of stokers, all operating under the same conditions.

W. P. Frey[6] said that his company burned 1,000,000 tons of coal a year for steam and electric power, and that he was interested in pulverized fuel as a possible means of utilizing the twenty-odd million tons of small coal lying on the ground in the anthracite regions. But as it was said to take twice as much power to pulverize anthracite as bituminous coal, and as the minimum wage for the anthracite union laborer was 43 cents per hour, this would make the cost of pulverizing the $1 coal in question about 75 cents, and he did not see how pulverizing would make up for this enormous difference. Firing a boiler at a high rating with anthracite required far more draft at the damper than the 0.10 to 0.15 in. mentioned in Mr. Harrison's paper, and in consequence stacks much higher than 40 ft. The fire-brick problem was a very important one, and he would be obliged if Mr. Scheffler or Mr. Barnhurst would give specifications for bricks that in the long run would stand the steady temperature of over 3000 deg. that they would have with their low supply of air, unless they reduced the temperature in the combustion chamber.

[4] Chief Engineer, Combustion Engineering Corpn., New York. Mem. Am.Soc.M.E.

[5] Head of Department of Mechanical Engineering, Purdue Univ., Lafayette, Ind.

[6] Fuel Engineer, Lehigh Coal & Navigation Co., Lansford, Pa.

C. W. Lotz,[1] in reply to Mr. Frey, said that in his experimental plant the cost of pulverizing anthracite was but 33 instead of 70 cents a ton. They were also burning coke breeze efficiently. As to stack heights, it was to be remembered that the furnace itself acts as a big stack and drives the gases up through the first pass of the boiler.

W. L. Wotherspoon[2] told of tests he had made some ten years ago in South Africa on a Bettington boiler fired with pulverized fuel and a B. & W. boiler with a chain-grate stoker. Both boilers were 1000-hp. units and the efficiencies obtained were practically equal. There were low-grade fuels (9500 B.t.u. and less) available in the Transvaal, and the results obtained with pulverized fuel were such that the plant was still in operation.

Lately he had been paying attention to the use of powdered coal where the combustion took place under pressure—for the generation of heat in a blast furnace smelting nickel ores. On a continuous 18-day run it had been found possible to replace 50 per cent of the coke used, which cost twice as much as bituminous coal. At the Tennessee Copper Co.'s smelter he had not only been able to replace all the coke with powdered coal, but to actually do the smelting with 25 per cent less fuel. Even better results were shortly to be expected. Their pre-war cost for drying and pulverizing was 40 cents per ton. Now it was practically double that figure.

The impression prevailed in the United States that the screw feed was necessary, but in Canada he had experimented and found that by using compressed air at 70 lb. pressure, 2½ tons could be transmitted in 5 min. through a 3-in. pipe over a horizontal distance of 1200 ft. and then elevated 60 ft. This method might prove available for the use of a central pulverizing plant supplying small, isolated power plants through an underground pipe line.

W. E. Snyder[3] felt that while pulverized coal was an ideal fuel in the cement plant, there were, nevertheless, many problems to be solved in regard to its use in steel furnaces and under boilers. The best modern stoker-fired plants showed very high efficiencies, and with the same expenditure of intelligence the pulverized-coal plant might be brought to equal them.

He had experienced difficulty in obtaining definite facts regarding performances of pulverized-fuel installations, and was skeptical as to the accuracy obtained in measuring the coal by observing the revolutions of the feed screw, for it did not always give the same quantity per revolution. Apropos of accurate measurements, Mr. Snyder caused considerable amusement by telling of the man in charge of a small power plant who had succeeded in overcoming troubles he had experienced with a venturi meter by merely boring out the narrow part!

Narrowing down the comparison of the two methods of getting coal into the boiler furnace, he said, it resolved itself into a very simple matter of reducing waste in the ashpit and up the stack,

[1] Pottsville, Pa.

[2] Consulting Metallurgist, International Nickel Co., New York.

[3] Mechanical Engineer, American Steel & Wire Co., Pittsburgh, Pa. Mem. Am.Soc.M.E.

and a possible saving in repairs and maintenance of the means employed to handle the fuel.

W. F. Verner[1] gave estimates that had been prepared covering the comparative costs of operating six 2400-hp. boilers at the Ford Motor Company's blast-furnace plant with pulverized fuel and with stoker fuel. The estimated cost for the pulverizer equipment and buildings was $691,000 and for a corresponding stoker plant $475,000. The cost of pulverizing per ton, including fixed charges, power, maintenance, lubricants, etc., and labor (at $8 per day), was $0.76; for transmission from pulverizing building to boiler room, $0.25; and for boiler room, $1.13; or a total of $2.14. For a corresponding stoker plant the figures were: for transmission from breaker building, $0.24; boiler room, $1.66; total, $1.90. For a plant with twelve 2400-hp. boilers the total for the pulverized-coal installation was $1.63, and for the stoker equipment, $1.49. These figures, in connection with the higher estimated efficiency of the pulverized-fuel plant, indicated for it a saving of 4 per cent over the stoker plant.

One important point in favor of pulverized-fuel plants was that the stand-by losses were reduced to a minimum as compared with stoker installations, where the fires had to be banked over the shutdown periods. An additional reason for installing the former was that blast-furnace gas would be available for use under the boilers and in quantity sufficient to carry the light loads.

John A. Stevens thought that the matter of stand-by losses brought out by Mr. Verner a very important one. In New England factories running on one shift of 9 hours a day, the stand-by coal required in the best hand-fired plants ranged from 20 to 25 per cent of the daily consumption. This, of course, decreased with more shifts, or with continuous runs of, say, 72 hours, as in paper mills. With stoker-fired boilers there was a loss in running full load right up to washing-up time—usually 10 minutes before the quitting hour, and also when burning a bank of coal on the grates and then rejecting it. The elimination of non-productive fuel in shop power plants was also claimed as an advantage by the advocates of oil fuel or the purchase of power from central stations. A prominent engineer had told him that 2¼ per cent of unconsumed carbon passes out of the stacks of these large stations, and to obviate this he trusted that an effective silt separator would shortly be developed.

R. Sanford Riley[2] said that the papers and discussion were valuable in directing attention to the problem involved in all combustion—the carburization of air. The final question regarding the two systems of burning fuel under consideration was which was the better carburizer, and he felt that in the long run the simpler apparatus would win out.

Edward N. Trump[3] spoke of experiments he had made about 25 years ago in burning powdered fuel under a 300-hp. B. & W. boiler. The furnace used had too small a combustion chamber, and the ash accumulated and blocked the passages between the tubes in less than a week. This ash had taken up tar from the combustion products and clung to the tubes, and it proved very difficult to scrape off. It was important, therefore, to see that the combustion chamber was large enough, and, as noted in Mr. Harrison's paper, that the boiler tubes and surfaces were carefully and frequently blown.

H. G. Barnhurst, in closing the oral discussion, said that there were certain arguments in favor of pulverized coal for certain localities and for certain grades of fuel which could hardly be overcome by any other method of burning. One point which had not been brought out was the fact that by pulverizing coal and burning it in a furnace the boiler installation was made entirely independent of any particular quality of fuel. In the course of experimenting his company had burned coal with as low as 2 per cent of volatile matter and up to 40 per cent with an ash content running as high as 51 per cent, just to show that the percentage of ash did not affect or interfere with the combustion conditions. Mr. Trump's main troubles, he thought, were due not only to the small combustion chamber used, but also to the fact that his coal was not finely pulverized. He wished again to emphasize the fact that the coal must be pulverized to a very high degree of fineness in order to get good results—two or three hundred million particles to the cubic inch. This increased the surface exposed to the air about 700 times over that which it was in the form of lumps, and made it very much easier to effect combustion. Moreover, various grades of coal could be burned which could not be handled on stokers.

As to the volume of a furnace per pound of coal burned per minute, he would not care to assign any particular value, because all combustion chambers had different shapes. The essential feature was low velocity of the gases, for the brick became plastic at high temperatures, and if subjected to the action of gases at a high velocity, the under rows of lining would be destroyed.

The question of furnace firebrick was, of course, very important, and the higher the grade used the better would be the results. The ash accumulation in the bottom of the furnace by further refinements might be cared for by movable hearths so that it would not build up in the furnace and interfere with the operation. The ash going out of the stack, in some cases, was now being recovered to a certain extent, and there was certainly a field for recovering ash not only from pulverized-coal-fired furnaces, but also from stoker-fired furnaces, because the percentage of ash from many stoker installations, under forced-draft conditions, rose very high.

Discussion of Mr. Weymouth's Paper on Arizona Power Plants Using Oil Fuel

Mr. Weymouth's paper treated of the performances of three steam-electric power plants situated in Arizona where load factor and high fuel cost demand economical operation. These plants are those of the Inspiration Consolidated Copper Company; the New Cornelia Copper Company; and the Arizona Power Company. Tables and curves of operating characteristics were given in Mr. Weymouth's paper and some of the difficulties encountered in practice were also enumerated.

C. H. Delany[1] (written). The Pacific Gas and Electric Company is operating at Sacramento, Cal., an oil-burning plant which is similar in some respects to the three plants discussed in Mr. Weymouth's paper. This plant was built in 1911 and is equipped with one 5000-kw. Curtiss turbine, Stirling boilers, Peabody-Hammel oil furnaces, and a surface condenser taking water from the Sacramento River. This plant was designed for 175 lb. pressure and 100 deg. superheat at the turbine throttle, and is therefore similar in this respect to the Inspiration Copper Co.'s plant. The plant, however, being essentially a standby plant, is not equipped with economizers, steel casings for the boilers, or automatic fuel-oil regulators.

In comparing the operation of different steam plants operating at variable loads, it is convenient to plot on a diagram the kilowatt-hours generated against the total oil burned, each point plotted representing the average results of a month or a day as the case may be. If a sufficient number of points at different loads is obtained, it is possible to draw a line through them representing their average, and this line in most cases is found to be practically a straight line. Such a diagram for the Sacramento station for the year 1918 is given in Fig. 1, and to it have been added points taken from Mr. Weymouth's paper for the three Arizona plants. The points for the Inspiration Copper Co.'s plant are sufficiently numerous to enable the line AC to be drawn through them, corresponding to the line AB for the Sacramento plant. It will be noted that these two lines intersect the ordinate of zero load at almost the same point, A, indicating about the same quantity of oil (that is, in the neighborhood of

[1] Pacific Gas & Electric Co., San Francisco, Cal. Mem. Am.Soc.M.E.

25 or 30 bbl. per day) required to operate either plant at no load.

There are not sufficient points to enable a similar line to be drawn for either the New Cornelia Copper Co. or the Arizona Power Co. plants. However, assuming the point A for zero load to be the same as for the Inspiration Copper Co., the line AD has been drawn as an approximate average for these two plants.

This diagram brings out more clearly than a mere statement of the kilowatt-hours per barrel of oil, though perhaps somewhat crudely, the essential differences between the various plants.

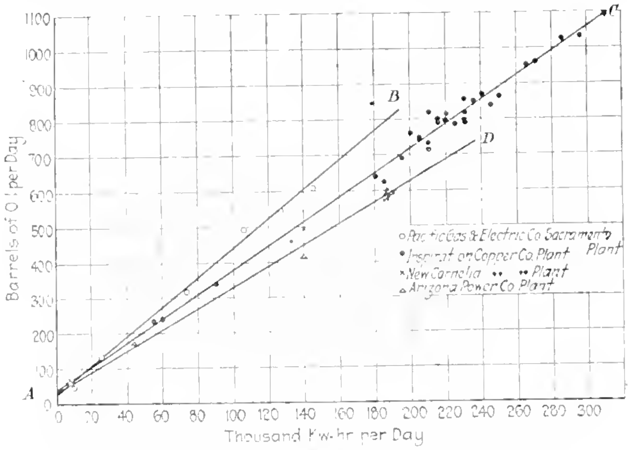

Fig. 1 Diagram Showing Relation Between Barrels of Oil Burned per day and Kilowatt-Hours Generated

Thus a comparison of the lines AD and AC shows at a glance the effect of the higher steam pressure, higher superheat and better vacuum carried at the New Cornelia Copper and Arizona Power Companies' plants. The line AC compared with the line AB shows the economy resulting from the use of economizers, steel casings, fuel-oil regulators, and other minor differences such as the greater age and smaller size of the turbine in the Sacramento plant.

W. W. Jourdin[1] (written). Referring to the fourth paragraph of the paper, the Inspiration power plant is equipped with engine-driven circulating units and barometric hotwell, with sealed sump and lift pumps located on a hillside at a sufficient distance below the condensers to secure positive drainage of the condensate therefrom.

The high-pressure cylinders of the blowing engines are being replaced with poppet-valved cylinders good for 250 lb. pressure, and all new equipment, including boilers recently installed, is designed for the higher pressure. However, until such time as the original boilers may be disposed of, a maximum of only 200 lb. pressure will be available at the throttles.

The cooling tower was not put into service until November 1918, therefore the plant operated under the handicap of poor vacuum, due to insufficient cooling capacity, throughout the period covered by the curves given by the author in his Fig. 3.

Figs. 1 and 2 do not represent present practice—in fact, there has been a very considerable departure in numerous operating features from the original instructions, although these in principle were good. Owing to labor troubles, the plant was shut down from July 2 to September 20, 1917, inclusive, and in the absence of detailed explanation concerning conditions, the curves would better be broken between June and October 1917.

The heat recovery is low in the economizers not so much on account of inadequate heating surface as because the recovery by the boilers is so high, compared with coal-burning practice, that little heat available for warming feedwater is contained in the gases to the economizers.

The Inspiration plant is jointly owned by two companies, and the money involved is so large, due to high fuel costs, that it is essential that the measurement of all quantities shall be so made as to secure the highest possible accuracy. The metering equipment is quite elaborate, and the accounting is on the basis of continuous overall plant test; consequently the operators are enabled to check economic performance more closely than is usually possible even in the most highly developed plants.

The economy reported is based on net electrical production, and no deduction is made for fuel consumed in warming up and stand-by due to changes in electrical load.

[1] Chief Engineer, Power Plant, Inspiration Consolidated Copper Co., Miami, Ariz. Mem. Am.Soc.M.E.

W. D. Ennis[1] (written). The maintenance of high overall efficiency in regular operation is a feature to be expected with well-designed plants using oil fuel. In discussing the reasons for the superiority of the New Cornelia plant over the Inspiration the author omits mention of the higher superheat used. Allowing for differences in pressure and superheat, the steam temperatures in the two cases are 471 deg. and 551 deg. The load factor may have been of weight also, but there seems to be nothing in the table dealing with this plant to show whether or not both turbines were running. If they were, the New Cornelia load factor was around 0.50 as compared with a value of about 0.70 for the Inspiration plant.

A most interesting feature of this paper is the indication of maximum boiler efficiency at about 0.60 rating (Fig. 2). The author attributes this to the tightness and insulating efficiency of the sheet-metal casing. It is regrettable that the boiler proportions are not given in some detail. The curve of boiler efficiency against rating cannot be considered a normal curve. The (actual) rate of evaporation at normal rating works out 3.26 lb., or at 60 per cent rating, less than 2 lb.

W. H. Best[2] (written). There is one particular point to be emphasized in the use of oil fuel in power plants, and that is the importance, wherever possible and wherever plants are of sufficient size, of the company's employing an engineer whose duties will be to see that the oil is properly burned in order that the strictest economy and highest efficiency may be attained and maintained at all times. I have always recommended this in power plants and in forge shops, and I am glad to learn that there is one plant in the United States that really has placed a man in charge, whose duty it is to see that the oil is properly burned. He can save his wages many times by the economy effected in fuel by his attention to his specific duties.

Why Does the Water in a Boiler Lift When the Safety Valve Blows? An editorial written in connection with a recent action of the Boiler Code Committee of The American Society of Mechanical Engineers in regard to the question of safety valves. An attempt is made to answer the question, "What lifts the water from the level of the water line and throws it out of the safety valve?"

When the valve opens the steam rushes out at a rate proportionate to its absolute pressure, resulting in a diminution of pressure in the area immediately below the valve.

When the boiler is steaming, there is, the editor states, no definite water level. The surface is tossing and heaving with the disengagement of steam bubbles. This disengagement will be very active for the first instant that the pressure upon the surface of boiling water is reduced and may be so active right under the valve as to throw up a column of water which, aided by the sweeping action of the steam rushing to the opening with the velocity of a cyclone, is carried out of the boiler.

It is claimed that this lifting action can be avoided by a gradual opening of the valve, the term "gradual" being used in a comparative sense. From this point of view and as far as the relations between the movement of the valve to the lifting of the water are concerned, it appears to be a question more of time operation than of valve lift, and a smaller valve with large lift does not necessarily give a more sudden release. (*Power*, vol. 49, no. 25, June 24, 1919, p. 983, *gt*)

The Organization of an Industrial Laboratory

Following This Paper is One on Industrial Research Laboratory Organization, and the Two, with the Discussion at the Research Session of the Spring Meeting, form a Valuable Digest of the Methods and Importance of Industrial Research

By A. D. LITTLE,[1] CAMBRIDGE, MASS., and H. E. HOWE,[2] CAMBRIDGE, MASS.

During the war industrial research in the United States was naturally stimulated, and as a result there now exists a deeper interest than heretofore in the applications of science to manufacturing processes. New laboratories will undoubtedly be built and many old ones reorganized in order to render more efficient service. It is the purpose of this paper to point out the organization and conduct of such a research laboratory.

The authors first outline the aims of a research organization, following which the divisions of the laboratory are enumerated and discussed, the laboratories of Arthur D. Little, Inc., being taken as a type. The methods of management, writing of reports and the commercial organization of the laboratory are also discussed at some length, and the paper concludes with a description of the building and equipment best suited to carry on this type of work.

PREVIOUS to the war there were about 375 industrial research laboratories in the United States, including those maintained by manufacturers for their own benefit, and commercial laboratories prepared to render similar service. At the present time there are no figures available regarding the number of new laboratories established as a result of the war, but there is no doubt but that the war created a deeper interest in industrial research, and the application of science to manufacturing processes. It is also evident that those laboratories which existed before the war are displaying a greater interest in fundamental research, and in rehabilitating their organizations are paying far more attention to the research phases of their problems than they have been willing to do heretofore.

In discussing the industrial laboratory we may choose between the one organized for the purpose of exploring some small corner of the broad field symbolic of our ignorance and an establishment concerned with the greatest variety of problems. A laboratory of the latter type should consist of a collection of special laboratories carefully articulated to produce results most efficiently, and the work common to all of them should be organized separately in a large general laboratory. Fortunately for our country there are several such laboratories doing splendid work, and notwithstanding the care exercised to avoid undue specialization, nearly all of them contain departments which dominate, due either to stronger men or the greater appeal which these departments make to the company; or perhaps to a seemingly greater importance of their class of problems at the moment. The great majority of these laboratories are maintained in the plants of industry at an annual expense running up to two millions in at least one case, and with many spending hundreds of thousands each year.

Another plan which should be mentioned involves the training of men as a primary consideration, and the Mellon Institute, at Pittsburgh, affords a conspicuously successful example of what may be done in educational institutions in solving the problems of industry, while at the same time men are trained in research.

The Aims of a Research Organization

Broadly stated, the aims of a research organization should be:

a To find, develop and train men

b To create such a background in the public mind as shall insure support for research and the industrial utilization of research results

c To secure coöperation between different branches of science, as, for example, between chemists and mathematicians

d To avoid repetition and duplication of effort, first by rendering present knowledge readily available to research workers, second by applying clearing-house methods to research projects

e To stimulate research by emphasizing the importance of specific problems, making special grants, rendering material and facilities as generally available as possible.

f To furnish a general staff for research which shall work out the plan of attack for major problems, assign the several lines to competent workers and coördinate and focus the whole

g To bring home to manufacturers the advantages of research with the view of promoting the establishment of private, corporation, and group laboratories

h To make and publish a census of available research facilities in men and equipment

i To survey the natural resources of the nation and direct research toward their development

j To appraise our great industrial wastes and develop plans and methods for turning them to profitable use.

As regards any research laboratory, it goes without saying that it is the personal factor which determines performance and this is preëminently true of the laboratory director. Sir Humphrey Davy truly said that his greatest discovery was Michael Faraday, and no greater problem is likely to confront a research laboratory than that involved in the discovery of a director. Successful laboratory directors may be of several types, but a militant optimism, contagious enthusiasm, controlled imagination and quick human sympathy are common to them all. Such a man will naturally in selecting his subordinates look for these personal qualities almost as carefully as he will weigh specialized scientific training, and having been thus guided in his selections will find it relatively easy to inspire throughout his organization those relations of good fellowship and that *esprit de corps* which multiply enormously the effectiveness of any working force.

The so-called commercial laboratory devoting its efforts to industrial research and operated on a strictly business basis will best serve our present purpose, and that of Arthur D. Little, Inc., in Cambridge, Mass., will be taken as a type in the belief that much of interest will be found in this establishment, which is "dedicated to industrial progress." During the past thirty-three years this laboratory has grown from a partnership of two chemists to an organization of sixty people, and scheme after scheme has been devised for the management of the enterprise, only to find new conditions and rapid growth calling for constant revision. Being a corporation, it is managed by the usual officers with a board of directors, all of whom do not devote their entire time to the business.

The Divisions of the Laboratory

Within such a laboratory there are two distinct sets of duties which may be designated as scientific or technical, and commercial or financial. These two divisions have at least two points in contact, one being through a service manager, and the other the department charged with obtaining new business for the organization.

Presented at the Spring Meeting, Detroit, Mich., June, 1919, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

[1] President, Arthur D. Little, Inc., Mem. Am. Soc. M.E.
[2] With Arthur D. Little, Inc.

The fundamental duty of the scientific division is to interpret the results of pure science in the terms of industry. While the work of the commercial laboratory is of the same order as that done in any laboratory even where the dollar is never discussed, it must be conducted with full recognition of the fact that many industrial problems are as intimately concerned with economic questions as with scientific. In other words, while for instance a laboratory process in glass may be intensely interesting and of fundamental importance, the client can hardly be expected to be satisfied with a report unless a commercial method for operating it can be devised. The technical work should be in charge of the president, under whom various departments should be organized, so that each phase of a given problem may have the attention of a specialist, provided with adequate equipment to facilitate the work.

In this connection it may be emphasized that it pays to provide congenial, inspiring surroundings for the laboratory worker. The laboratory can be made attractive without being ornate, or involving unreasonable expense, and every effort should be made to have the workers reasonably happy. Under no other condition can the best work be expected, and it must be remembered that the heaviest investment is in the time of these workers, the salary cost being much greater than that for equipment or material maintenance. Rewards other than monetary for faithful service also play an important part.

The departments into which the technical division are divided will naturally differ in each laboratory, but a fairly definite line can be drawn between research, engineering and standardized or routine work. It is advantageous to have all of the standardized work, including that incident to research and engineering, carried on under one department head, for in this way it can be done to better advantage both as regards efficiency and economy.

The research department should be organized for both laboratory and small-factory-scale work. There will be a multiplicity of subjects, and since special facilities cannot be provided in advance of close acquaintance with the problem, the organization of departments for research along special lines will concern personnel more than a division of floor space or equipment.

Engineering will embody plant inspection, design, construction and operation, and although much of its work will be in the field, many phases of its problems will be worked upon concurrently in the laboratory.

The analytical department will be subdivided under such headings as textiles, fuels, food, metallurgy and metallography, chemical microscopy, water, lubricants, construction materials, pulp and paper, fermentology, etc. Some of these subjects will require special accommodations, while others can share a large laboratory which provides space for certain apparatus kept in place for a large number of similar determinations.

Nothing is more expensive or demoralizing than experimentation in the plant. An industrial research laboratory should therefore be adequately provided with equipment of semi-commercial size. Infant mortality among processes is high in any case and the most critical period in their young lives is that covering the transition from the laboratory to the plant. They require and the research laboratory should provide a nursery to protect and foster them during this period of their development. Some large manufacturers have even found it desirable to operate in connection with and under the sole direction of their research laboratory a small plant in which actual commercial manufacture is regularly conducted. Such extension of the laboratory's function permits the complete reduction to practice of new methods and the commercial demonstration of the sufficiency of the product before the innovations are introduced into the main plant.

Even when no such provision appears feasible, it is, nevertheless, highly desirable to have the industrial research laboratory actually engaged in some small scale, highly specialized, commercial manufacture, preferably of some product which it has itself originated. The least advantage of this procedure is that such manufacture of a properly selected product may frequently defray a substantial proportion of the expenses of the laboratory. The major benefits are the acquirement of a certain commercial sense by the laboratory staff, an appreciation of the conditions and difficulties of actual production, and finally the strengthening of the position of the laboratory through the increase in its turnover and equipment.

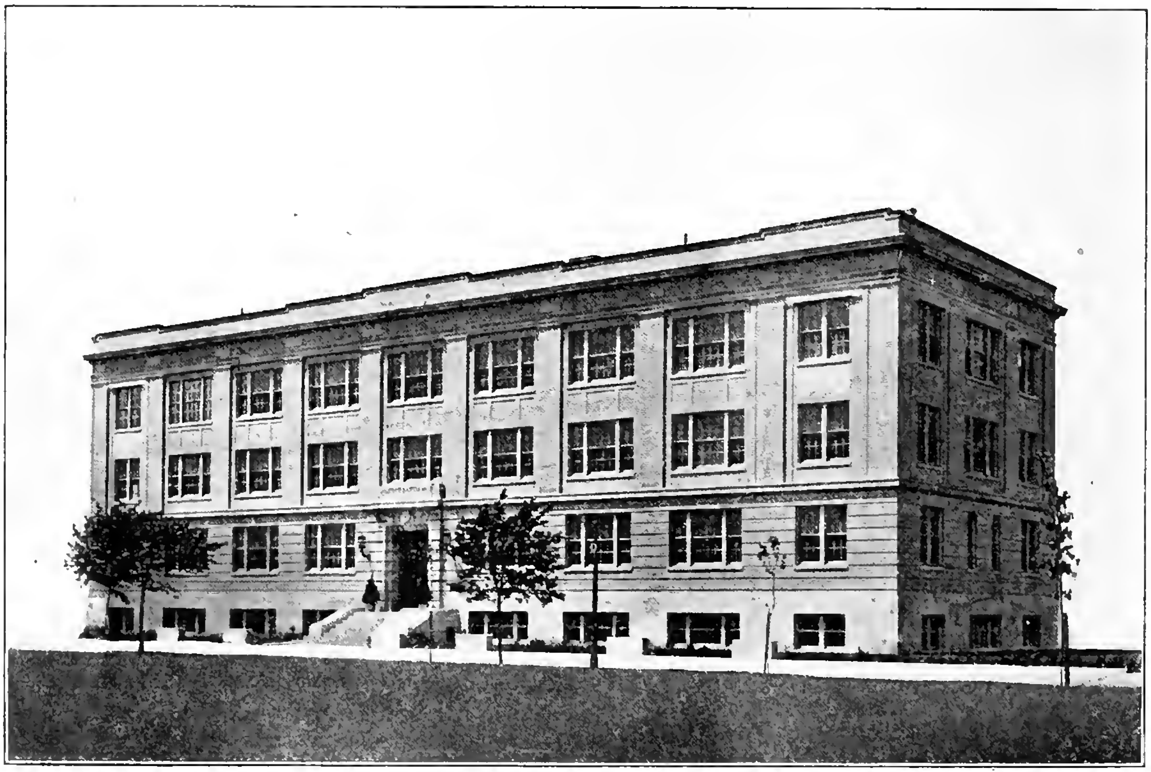

Fig. 1 The Laboratory of Arthur D. Little, Inc.

The Method of Management

It is easy to visualize the organization chart for such a laboratory, and a brief description of how a new piece of work will be handled may therefore convey a better idea of the method of management. The authorization for the work will go to the service manager, who sees all incoming mail, and to the authorization will be attached any correspondence or data bearing on the case, all of which will be given a case number for identification, and this number will be entered in a case register, which will indicate the name of the client, the subject of the problem, the date the authorization is received and the date when the work shall have been completed. The service manager, who must be familiar with the ability of each member of the staff, as well as with the work in hand, will assign the case to the division which can render the best service. Conferences will then be called, into which any member of the organization who can contribute anything to the solution of the problem in hand will be drawn, and outside associates or independent consultants may be included. The problem will then go into work by means of instruction sheets, setting forth what is to be accomplished, suggesting methods of attack, relating any special circumstances, references to literature, and standard methods which may be applicable, and as much light as possible given to the individual who is to do the work. Accompanying the case there will be a tag bearing the case number and upon it a date at which it is expected the work can be completed, or a progress report made, must be indicated. The tag is then returned to the service manager. Through the means of data sheets, time slips and verbal reports the progress of the problem will be readily followed. This procedure will be followed in all the divisions, the individual reporting to his superior, and the service manager will be alert to insure prompt and efficient service to all clients.

At the completion of the work the report, varying in extent from a single printed form to a bound volume of several hundred pages, will pass through the hands of all concerned, and will thus be distinctly the report of the organization and not of an individual in the organization.

Reports

Writing a report requires skill, for it must be comprehensive. It should begin with a clear statement of the problem, followed by the conclusion reached as a result of the work, which may then be described in detail. Patents, cost data, tables, graphs, photographs and samples should be dealt with in an appendix, and in some instances descriptions of apparatus should be included. The whole must be carefully indexed, and a copy sent to the library to be bound and kept as confidential information in locked cases, but as part of the library it should be carded for the library card index. Obviously no fast rule can be laid down for writing reports, but it should be borne in mind that many of those who read technical reports are not interested in minute details, and that the subject-matter must be presented in a form that will be interesting and understood by the layman. It must also have its important points so emphasized that they can be readily picked out by those not caring to read the entire report, but at the same time it should include sufficient data to serve the purpose of a fully qualified technical man to whom the report may be referred at some later time.

This brings up the question of the library, which may easily be considered the backbone of the industrial laboratory. Its extent will depend upon other library material available in the community but there are few things which obstruct research more seriously than the absence of easily accessible proper library facilities. A few dollars spent in books and literature frequently saves as many hundreds otherwise spent in work of duplication. The useful periodicals must be provided, elaborate indexes will be found a good investment, also abstracts and patents; in short, every means for quickly locating literature references should be at hand. The current literature, with articles of interest indicated on an attached slip, should be circulated among the members of the staff whose names are checked on this slip, and some one, preferably a chemist, should have assigned to him the task of constantly reading the literature in order that no scrap of information shall escape. Such a chemist-librarian will conduct searches in other libraries, prepare abstracts, and in fact direct

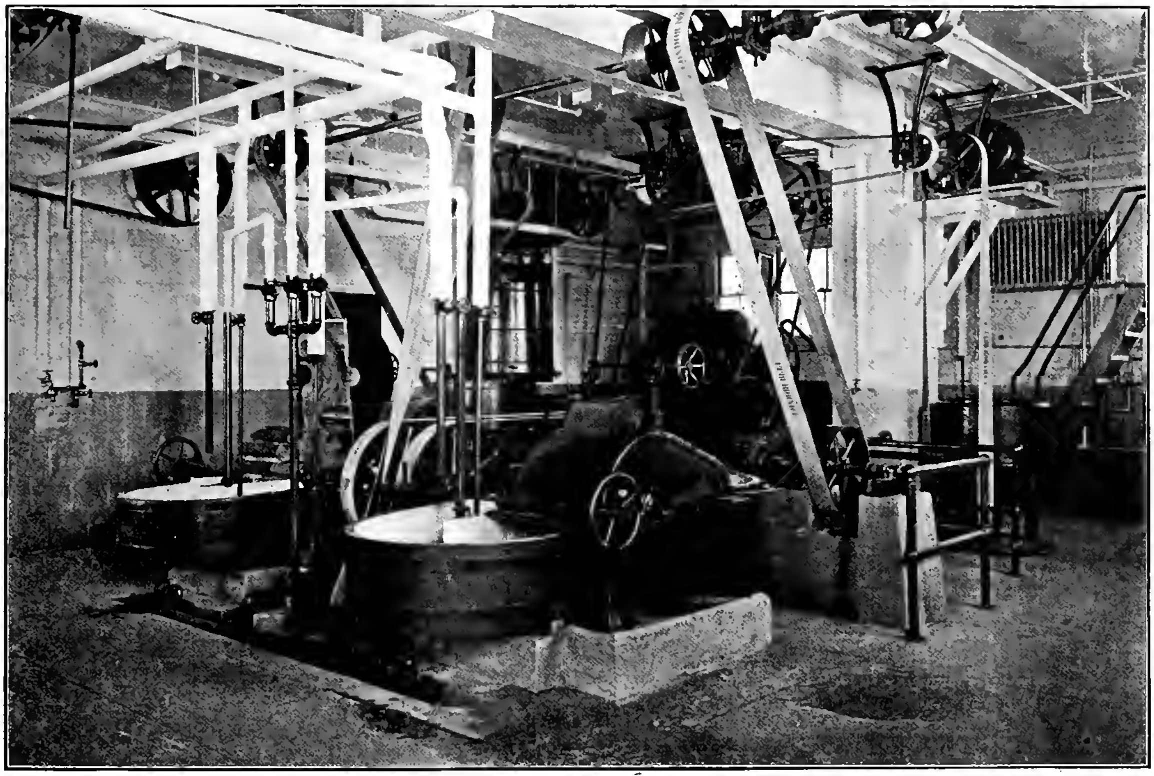

Fig. 2 Experimental Paper Mill, Laboratory of Arthur D. Little, Inc.

the information service for the laboratory, and through the laboratory to its clients.

BUILDINGS AND EQUIPMENT.

With this general plan of management before us, we may now consider the equipment and space required for effective work.

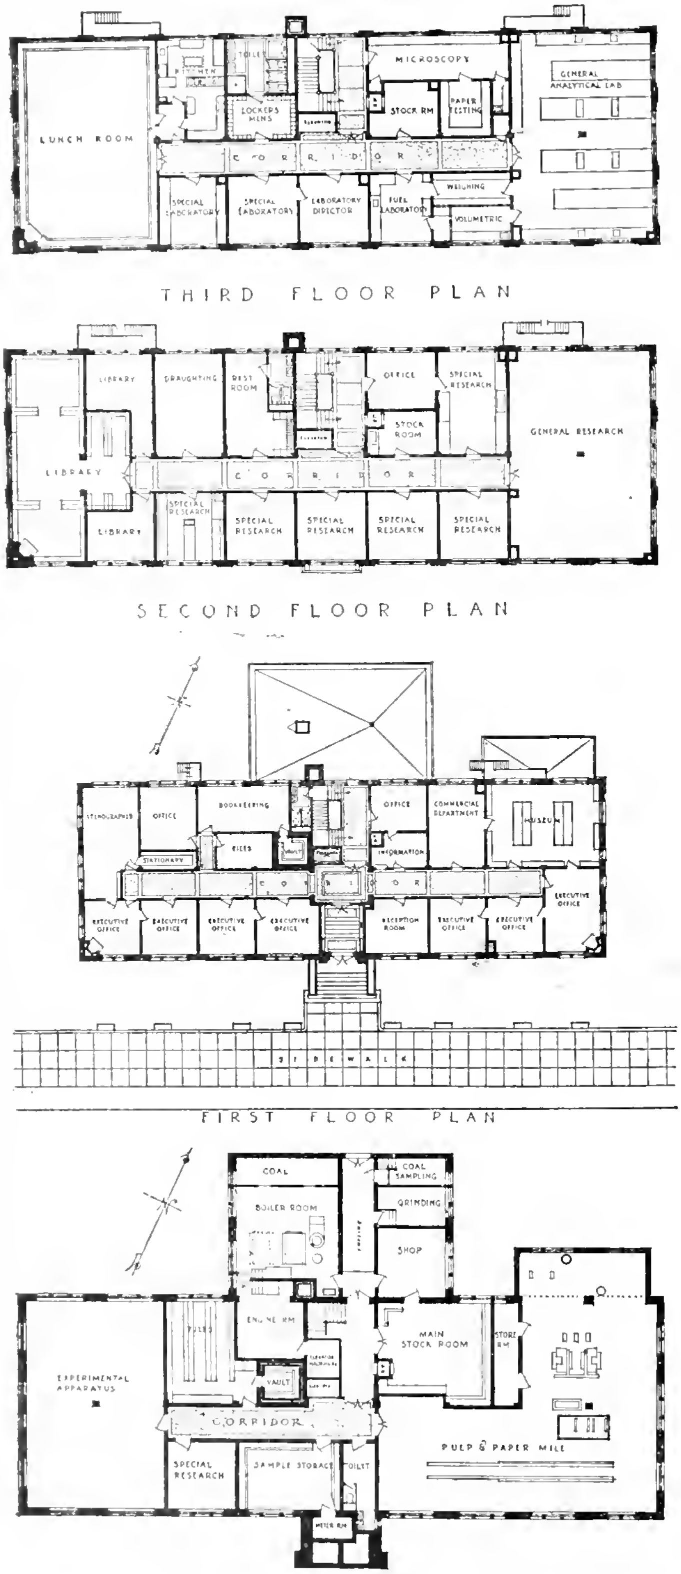

FIG. 3 PLANS OF THE LABORATORY OF ARTHUR D. LITTLE, INC.

Experience has shown that a satisfactory building is one approximately 50 ft. by 150 ft. (planned so that another building may be easily connected in H-formation) and consisting of a basement, with three floors, the basement itself being so designed that it is as light and airy as the upper floors. Such a building with a wing housing the power plant and small grinding rooms (this being the connected wing of the H) has a total floor space of approximately 30,000 sq. ft. The building occupied by Arthur D. Little, Inc., is of this type and the various departments are allotted the following space: Analytical division, 5328 sq. ft.; research division, 3458 sq. ft.; engineering, 1155 sq. ft.; commercial department, 768 sq. ft.; management (meaning the management of outside enterprises), 538 sq. ft.; special department devoted to pulp and paper, 4118 sq. ft. The portions of the building which are non-producing, such as miscellaneous offices, which includes stairs, corridors, halls, lavatories, etc., comprise 8000 sq. ft., and the space unassigned amounts to 3815 sq. ft. This includes laboratory space provided for emergencies and expansion but not in constant use.

These area measurements form the basis of apportioning overhead due to interest on investment, depreciation, repairs, insurance, upkeep, etc., and among the departments is distributed the charge for carrying 768 sq. ft. devoted to an industrial museum and 1536 sq. ft. devoted to the library.

The basement will provide room for the power plant, the current sample room, the general stock room, two very large rooms for small-factory-scale equipment, two small rooms for coal and other crushing and grinding operations, and a machine shop in which the physical testing machinery can be installed. A laboratory for testing construction materials, such as cement, may also be placed in the basement to advantage, and here, too, a room and vault can be set aside for inactive letter files and records.

The first floor will provide a series of offices each of about 250 sq. ft. area, two larger ones which may be used by officers of the company, consulting engineers and others, a reception room, and an information booth with switchboard. The museum can also be on the first floor, together with the rooms devoted to the commercial department's work. Quarters for the financial division, with ample vault space, and room for current correspondence and the general stenographers' office complete the floor. The engineering division might also occupy rooms on the first floor.

The second floor may be properly devoted to research and the library. It is frequently advantageous to be able to segregate research problems, and it will be well to provide a series of small rooms, say of approximately 250 sq. ft. in area, which can be fitted up in accordance with the requirements of the problem, and easily dismantled at the conclusion of the work, to be refitted according to the next undertaking. A branch stock room should be located on the second as well as the third floor, and these should be served by elevator from the general storeroom in the basement. There are always a number of scattering problems in research that can be handled in one laboratory, and so a special-problems laboratory should also be provided on the second floor with an office for consultation purposes. Finally a large room, say of 1500 sq. ft., should also be available for large undertakings, and as a space for emergency overflow.

The third floor may comprise the general analytical laboratory, a room of about 1500 sq. ft., adjacent to which should be a room for titration and the balance room (each of approximately 125 sq. ft.), a fuel-testing room and a special room for extraction. A branch stockroom and the offices of the head chemist and assistants should also be on this floor. The optical room should be placed where north light can be obtained, and a small dark room must be provided, as well as a specially equipped room for the physical testing of paper and textiles. The kitchen can adjoin the assembly room. A locker room for the men and a rest room for the women must also be provided. Space under the roof can be used for fans and a ventilating appliance, water tanks, etc.

Such a building as has been thus briefly described will cost about $200,000 and $50,000 will provide general equipment. There is always something new to buy for a laboratory. Such an establishment will provide working space for approximately 150 people, and more could be accommodated if necessary, depending largely on the type of work being conducted. The cost of operation and maintenance, based on a staff of sixty, will be about $20,000 per month.

Industrial Research Laboratory Organization

By K. C. Mees,[1] Rochester, N. Y.

The great value of scientific research, both to the industries and the nation at large, is now generally recognized. The industrial research laboratory is an important factor in maintaining the supremacy of an industry, and its success depends to a considerable degree upon its relation to the other departments of the company with which it is associated. In this paper these statements are discussed, and the author presents his views regarding the establishment and function of industrial laboratories, giving in connection with the latter three annular diagrams. The form and operating costs of industrial laboratories are also discussed.

THE triumphs which have already been won by research laboratories are common knowledge. The incandescent-lamp industry, for instance, originated in the United States with the carbon-filament lamp, but was nearly lost to this country when the tungsten-filament was developed, only to be rescued from that danger by the research laboratory of the General Electric Company, who fought for the prize in sight and developed first the drawn-wire filament and then the nitrogen lamp; and we may be sure that if the theoretical and practical work of the research laboratory of the General Electric Company were not kept up, the American manufacturers could by no means rest secure in their industry, as, undoubtedly, later developments in electric lighting will come and the industry might be transferred, in part if not completely, to the originators of any improvement. Manufacturing concerns and especially the powerful, well-organized companies who are the leaders of industry can, of course, retain their leadership for a number of years against smaller and less completely organized competitors, but eventually they can insure their position only by having in their employ men who are competent to keep in touch with and to advance the subject, and the maintenance of a laboratory staffed by such men is a final insurance against eventual loss of the control of its industry by any concern.

The success of an industrial research laboratory depends to a considerable extent upon its position in the organization and upon its relation to the other departments of the company with which it is associated.

If industrial enterprises had been organized afresh with the research laboratory as a definite part of the organization, it is probable that by this time some general opinion would have been formed as to the position which the laboratory should occupy, but in fact nearly all industrial research laboratories have been added to organizations already formed, and their relations to the other departments of the organization are usually closely associated with their origin.

Laboratories are established in many different ways. If there is a technical scientific expert in the executive of the manufacturing company he may feel the need of a laboratory and become its director, and in this case the laboratory will necessarily be very closely associated with the work of the executive who initiated it.

A laboratory may also be established under a separate director, not himself associated with the executive officers of the company, but as a reference department for the executives, and in this case also it will be very closely associated with the officers of the company and will tend to be concerned more with questions of policy and the introduction of new products than with any other of the problems of the company.

In a large company a research laboratory may be established as a separate department, having its own organization and being available as a reference department for all sections of the company, in which case its activities will cover a very wide field, but at the same time it will not have as direct an influence upon the policy of the company as will happen if it is closely associated with one or more of the executive officers.

The earliest research laboratories grew out of the works testing and control laboratories and were therefore responsible directly to the works manager. More recently, laboratories have generally been established as independent departments of the company and responsible only to the general manager.

The executive official to whom the laboratory should report will depend upon the nature of the work to be done. There may be industries in which research work is required for only a single department, and in this case the research workers should be responsible to the head of that department; there are others in which the interest in the research is confined to the works, and in such cases the laboratory should be responsible to the works manager; but in most technical industries research work will have a great bearing not only on the methods of production but even on the general policy of the industry, and in such cases it is necessary that those who direct research should be in touch with, and responsible to, the executives who control policy.

The position of the research laboratory in an industrial organization is perhaps best determined by the criterion that the research department should be responsible to the officer of the company who is in charge of the development of new products. If the introduction of new products is in the hands of the works organization, then the research department should be responsible to the works manager; if there is a definite development department, or, if new products are introduced through the agency of some definite executive, then it is to that executive that the research department should be responsible. The research laboratory, in fact, should primarily be associated with development.

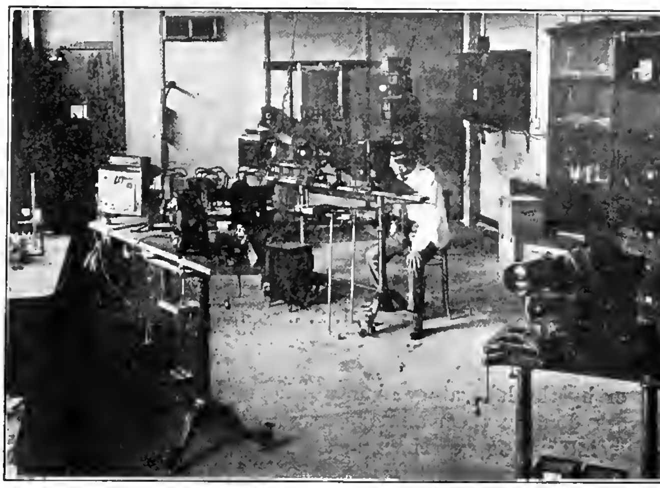

Fig. 1 A Laboratory of the Eastman-Kodak Company

The chief functions of the laboratory are as follows:

1 The provision of information regarding the technical and scientific matter in which the industry is interested, and the supply of this information in a form suitable for the education of the employees, of the customers, and of the general public.

2 Service in the form of the provision of specifications and standards for materials, the making of analyses and tests, assistance to the works in regard to difficulties and to customers in the relation of problems arising from the use of the product.

3 The development of new processes or products, utilization of by-products, the development of new departments of the industry.

These functions may be expressed by means of annular diagrams such as those shown in Figs. 1, 2 and 3. Fig. 1 shows

Presented at the Spring Meeting, Detroit, Mich., June, 1919, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

[1] Director of the Research Laboratory of Eastman-Kodak Company, Rochester, N. Y.

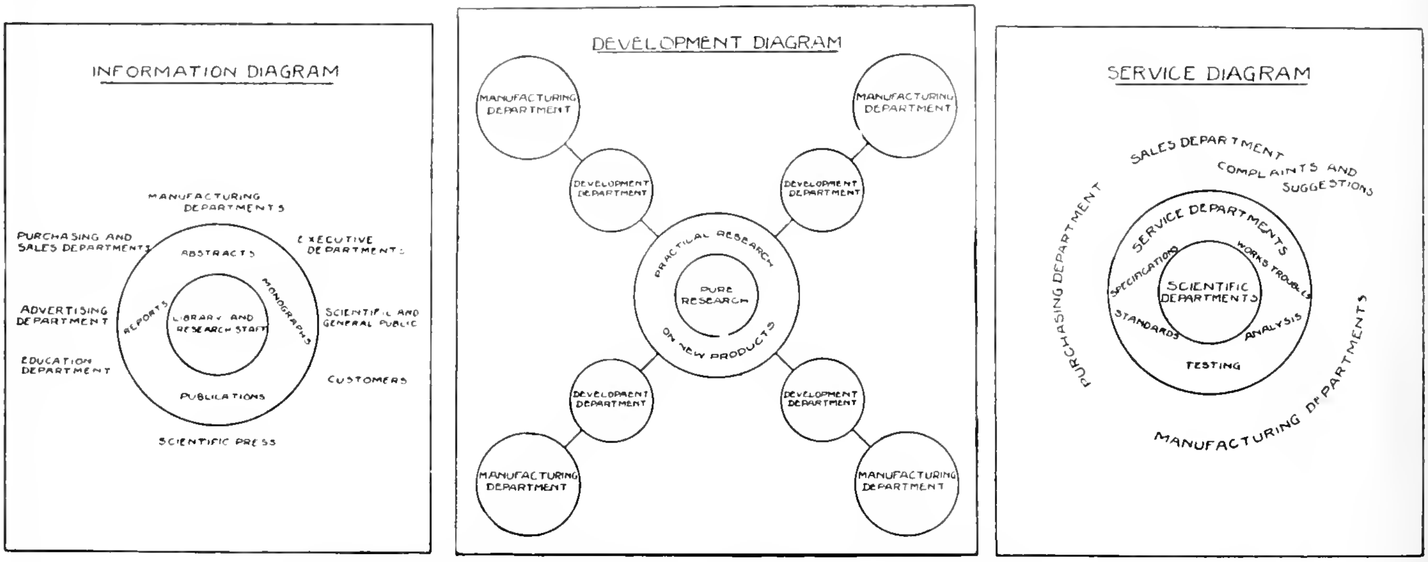
the information diagram. The information originating from the library and from the research staff is issued in the form of abstracts, reports, scientific publications and monographs, and first goes to the executive, manufacturing, purchasing and sales departments for their information; then to the advertising and educational departments to be placed in the form required for publication in the scientific and general press.

The organization of the development work is shown in Fig. 2, where the work is shown to be founded upon pure research done in the scientific department, which undertakes the necessary practical research on new products or processes as long as they are on the laboratory scale, and then transfers the work to special development departments to form an intermediate stage between the laboratory and the manufacturing departments. These development departments are really small scale manufacturing departments which may be operated either by the works department or by the laboratory; but which are controlled, as regards the work done in them and the method used, by the laboratory itself, being run as experimental departments in order to develop a new process or product to the stage where it is ready for large scale manufacture.

Under the alternative or cell system the laboratory consists of a number of investigators of approximately equal standing in the laboratory, each of them responsible only to the director, and each of them engaged upon some specific research. Each such investigator, of course, may be provided with assistants as may be necessary.

In practice, some system between these two systems of organization is essential and will develop in any laboratory. It is not possible to work a rigid divisional system, and on the other hand no cell system in its most definite form could be effective.

The scientific work of the research laboratory is best directed by means of a conference or series of conferences of all the men having knowledge of the subject, and this will have the further advantage that, while it will relieve the director of the details of the direction of the scientific work, it will keep him constantly informed as to all the work going on in the laboratory.



FIGS. 1, 2, 3 DIAGRAMS ILLUSTRATING THE FUNCTIONS OF AN INDUSTRIAL RESEARCH LABORATORY

In Fig. 3 the service diagram shows the scientific divisions as the operating center, each of which supports and controls the necessary service departments which prepare specifications and standards, undertake testing and analysis, the investigation of works troubles, complaints of customers, and suggestions from the sales department, the results of which are communicated to the departments interested.

The laboratory organization will therefore consist of a section of administration, which will be responsible for the direction of the work, the control of accounts and the issuing of reports; a section of information, which will operate the library, prepare abstracts of the literature, keep in relation with the patent department and constitute its technical wing, and prepare reports and publications of all kinds; and the scientific section, which will carry on the operation of the laboratory work.

There are two forms of organization possible for the scientific work of the laboratory. For brevity these may be spoken of as the "divisional" system and the "cell" system. In the divisional system the organization is that familiar to most businesses. The work of the laboratory is classified into several divisions; physics, chemistry, engineering, and so on, according to the number necessary to cover the field, and each of these divisions has a man of suitable scientific attainments in charge of it. In a large division each of these men will in turn have assistants responsible for sections of the department, all the heads of divisions finally being responsible to the director of the laboratory.

From various sources, but chiefly from the convenient list of American laboratories given by Fleming there can be found the cost of a research laboratory per scientific worker employed. It might seem that there would be very great variations in this, but, provided that the laboratories are all of the physical and chemical type, there is a surprising agreement between the figures, which show that the cost of building and equipment for a laboratory will be between \$3000 and \$4000 per man. From the same sources the annual cost of maintenance of such a research laboratory appears to be slightly lower than the first cost. Probably \$3500 per man will be a fair estimate of the cost of maintenance, and of this we may take 60 per cent as representing salaries and wages and the remainder all other expenses.

As laboratories are organized and experience gained in the types of laboratory suitable for different industries it will doubtless be possible to lay out definite schemes of organization for a laboratory suitable for the requirements of any industrial undertaking. At the present time, however, it is possible to do this only in the most general way, and it is necessary to consider each case independently, taking into consideration the requirements of the particular industry involved.

Fortunately data on this subject are being accumulated at the present time and the whole question of laboratory organization is being studied carefully both here and abroad. In this country the National Research Council has appointed a special committee to promote industrial scientific research and this body is now engaged in drawing up a scheme for the establishment of an alloys research laboratory and is considering other lines of industrial research all of which I am sure will meet with the approval and support of The American Society of Mechanical Engineers.

DISCUSSION AT RESEARCH SESSION OF SPRING MEETING

THE Spring Meeting of the A. S. M. E., held at Detroit, June 16 to 19, devoted its second session to a consideration of the status of research in this country. Four papers and an address were delivered. Those by Arthur M. Greene, Jr., on The Present Condition of Research in the United States, by Enrique Touceda, on Research Work on Malleable Iron, and by G. H. Clevenger, on The Division of Engineering of the National Research Council, appeared in abstract form in MECHANICAL ENGINEERING for July and in this issue the remaining two are presented. One of these, by Arthur D. Little and H. E. Howe, is on The Organization of an Industrial Laboratory, and the other, by Dr. C. K. Mees, deals with The Organization of a Research Laboratory. Abstracts of the discussion of these various papers follow and it is not surprising to find that opinions regarding the value of research vary but little, for it is unquestionably true that research is rapidly coming into its own and bids fair to occupy to a considerable extent the attention of the industrial world.

P. F. WALKER[1] (written). The author has truly said that in most of our educational institutions the members of the faculty are so burdened with routine teaching that large amounts of research work cannot be expected. There is good reason, however, why the schools need to give active attention to scientific investigation. It is the schools that must produce the men to go into active professional work, including research. In the schools these men have implanted in them certain ideals which will remain, perhaps unconsciously, as determining factors in their lives. To promote research is therefore of vital importance in order that the students should be brought face to face with research problems, and thus imbibe something of the spirit of the investigator.

A matter in which the writer is at present personally interested and to which he is giving a great deal of attention is the state industrial problem. It is a research side of that new branch of the profession sometimes designated as industrial or commercial engineering. Every state and every community has problems peculiar to itself and it is a function of state educational institutions as well as of the engineering profession to interest themselves in such problems with the aim of rendering service. A combined survey and study of industrial possibilities is being made. This is mentioned here because it is a kind of research not always thought of as coming within the scope of the engineer. To the writer, however, it seems that it is an activity which comes distinctly within the terms of that definition which states that engineering is the application of all of the sources of power to the use and convenience of man. In any community, and particularly in one where the natural resources are not yet developed by industries to the full extent that economic conditions will warrant, it is the business of the engineer to encourage and pave the way for new industrial development as truly as it is to develop the natural agencies for its successful prosecution.

F. J. SCHLINK[2] (written). The importance of real research work and its possibilities in returning a quite extraordinary profit for a very moderate expenditure, cannot be overemphasized. If this end is to be attained, however, the venture must be undertaken with a broad vision and the investigator must be permitted within reasonable limits to carry on studies which may not promise immediate pecuniary benefits.

It is nothing less than astonishing to find, as we occasionally do, that a long-established product, supposedly fully standardized, is being manufactured without even a superficial knowledge of the simple engineering and scientific facts that underlie its performance. Some of the portable or hand-operated fire extinguishers are splendid examples of this class, and in these simple devices, which are not nearly so complex, from the designing and manufacturing standpoint, as an alarm clock or a lawn mower, the varied and manifest types of mechanical and operating failures presented are well-nigh unbelievable. One can say with a high degree of certainty that the expenditure of \$500 in a real engineering study of the problems of materials and function in any one of several such extinguishers would have made unnecessary the waste of many thousands of dollars in ineffective designs, some of which are absolutely a menace in that they give the user a false and unfounded sense of security against fire hazards.

The condition of American business in which large profits could be made without the necessity of careful and rigorous attention to engineering research and standardization, is rapidly passing away in the face of the present perplexing industrial situation. The advancing costs of labor and material with the concurrent unwillingness of the public to pay increased prices for the manufactured product it consumes, are bringing to every manufacturer a problem of almost crucial character, of holding down or reducing his manufacturing costs without depreciating his product. This difficulty must be met on the one front by research and standardization, and on the other by the efficient management of labor; and the former, though not so well advertised or perhaps even so highly regarded, is likely to prove at least as powerful an ally as the latter.

ARTHUR J. WOOD[1] (written). In his paper, the author states that one of the great needs of the present time is for research men and then follows this with a statement which in itself explains why there are not more men available. He says, "The love of the work will prove to be the incentive as in many cases the monetary returns are small." I believe that the author is conservative in saying "many cases,"—it should read "most cases."

Monetary returns will never make a research engineer out of one whom nature never fashioned for such work, but it will produce results of unmeasured value from the one who has the love of and ability for research work if it frees him from financial cares which he otherwise must carry.

Surely the need is for more research men and the industrial laboratories look primarily to the colleges for their material, but what are the colleges, as a whole, doing to develop men along these lines?

In the period of awakening to the value of research there will be plunges into subjects without proper preparation or preliminary study and analysis and some half-baked results of tests will doubtless be put forth as research, partly because the colleges cannot or do not pay salaries to teachers and investigators which would train the right men in the proper lines. The making of a research worker is a long-time process, and it calls for a normal, straight-thinking mind, well informed and evenly balanced, which must be left free to get results. One of the apparent needs for men in collegiate research is for more leisure in which to think out methods, to plan work in fields not already well occupied and to keep the mind thoroughly saturated with the subject at hand. How much leisure should be granted? The man himself should be the one best qualified to answer this.

Regarding industrial vs. pure research, there should be no conflict; no line of demarcation can be drawn between the two although they are essentially different. One is helpless without the other. No research is so "pure" but that it may some day lead to results of commercial value. It is unfortunate that many engineers do not have a true conception or an adequate appreciation of the value of scientific research.

The Society through its Committee on Research and the various sub-committees, may also be an important factor in guiding the pioneer work. It may help to raise the standards of pure research so that industrial and educational institutions alike will accept the definition of research as given by the late Dr. R. H. Thurston as "the art of revelation and prophecy." The Society must be a leader in the great work and place research in its accepted and well-deserved place among engineering enterprises.

H. S. Coleman.[1] The system of research at the Mellon Institute was formulated by the late Robert Kennedy Duncan and placed in experimental operation at the University of Kansas in 1906. In 1911 the system was inaugurated at the University of Pittsburgh, and in 1913 established on a permanent basis there through a gift, by Messrs. Andrew William and Richard Beatty Mellon, bankers of Pittsburgh, of a modern research building and an endowment to cover the general overhead expenses and salaries of the administrative staff.

Any company or association of manufacturers having a problem or group of problems requiring investigation may become the donor of an industrial fellowship by contributing to the Mellon Institute a definite amount of money, for a period of not less than one year. This foundation sum must be adequate for the purchase of all necessary special apparatus or other equipment as well as to furnish the annual stipend of the research man or men selected to work on the particular problem. The Institute houses the investigatory work, furnishes it with the use of its permanent equipment, affords library and consultative facilities, gives careful direction to the progress of the research, and provides an atmosphere which is conducive to productive inquiry. All results obtained during the course of the industrial fellowship belong exclusively to the donor.

The institute is not, in any sense of the word, a commercial institution, being entirely independent and deriving no financial profit from any investigation conducted under its auspices. In fact, during the last fiscal year, it was necessary to draw upon the endowment fund for almost $70,000.

Up to the present time the engineering research carried on at the Mellon Institute has been rather limited in scope as the present building and equipment were designed mainly for chemical research. There are, however, three fellowships at present in operation involving engineering research, and plans are now under way for the construction of an engineering research building which will provide adequate facilities for extensive engineering investigation.

Investigations are usually worked out in three stages. First, there is the laboratory stage; then comes the unit plant or semi-commercial stage and finally the process is placed on a commercial basis in the plant of the donor. The fellow who has developed the process through the laboratory and unit-plant stages is usually at this time taken over by the company and placed in direct charge of the new process.

As a result of the investigations involving the development of new processes, a large and valuable collection of special equipment has been acquired. This equipment, in most cases, becomes the property of the Institute at the expiration of the fellowship for which it was purchased, and is available for further use in connection with new problems.

John R. Allen.[2] About a year ago, the American Society of Heating and Ventilating Engineers decided to establish a research laboratory, and the committee in charge of the work decided to associate themselves with the Bureau of Mines, as the Bureau agreed to provide the necessary laboratory space.

The funds that have been provided for the laboratory have come largely from manufacturers and others interested in the work; although the work in general will not be of a commercial nature but rather of a fundamental character. With that consideration in view the committee has laid down three principal activities for the institution: first, the obtaining of data covering the subject of heating and ventilating; second, the establishment of standards for the use of heating and ventilating engineers; and third, the work of research.

The work of research has been divided into two departments, one to be conducted at Pittsburgh and the other at the mines. Many of the laboratories in this country that are doing research work along the lines of heating and ventilating can materially assist our laboratory and thus the work of acquiring information on the subject of heating and ventilating can be accelerated. In the Bureau of Mines itself the principal work to be done is in connection with the subject of ventilation as this is one of the most difficult questions to be considered.

Zay Jeffries.[1] The Aluminum Castings Co. is engaged in a line of endeavor which for a long time has been determined by research that has been largely limited to the more refined methods of production. As a parallel to our line of work, the American Smelting Refining Company's method of research is something, which while it might not be termed research in an ordinary concern, is nevertheless very highly specialized. They examine a great many prospects and I believe in a certain three-year period, ending about 1916, they had examined about 900. At that time they had selected three for purchase and further development. That is a type of research work that one does not ordinarily come upon, but it nevertheless is considered essential for their business.

The Aluminum Casting Company's laboratory employs between 80 and 90 individuals. It is a two-story building 50 x 230 ft.; and its equipment is valued at approximately $150,000. The annual expenditure for this work alone, is about $300,000. We are finding out a great many things in connection with the non-ferrous alloys, but we have only advanced far enough to begin to apply these fundamentals to our industry. Our work is new, and yet its application is even now finding itself here, and no doubt will find its way further in the future.

Charles Russ Richards.[2] Some 25 odd years ago the first effort was made to provide for congressional action in engineering experiment stations, but for one reason or another the efforts to secure action of Congress were futile. A few years later the officers of the College of Engineering, University of Illinois, succeeding in interesting their board of trustees in engineering research, and in December 1903, the Engineering Experiment Station was organized and it has since undertaken, in a rather systematic fashion, the conduct of research in a great variety of lines. This is an organization within the college of engineering. Each member of the faculty is encouraged to devote any time he may have at his disposal to conduct research work. If he has a good problem which he wishes to undertake, we undertake to relieve him of exacting teaching or administrative duties, to permit him to give time to the work. The principal portion of our work, however, is carried on by the research corps, which is composed of various full-time and a number of part-time students.

In addition to the work which we are doing in research, there have been from time to time coöperative investigations of problems undertaken at the direct request of an industry or group of industries. At the present time there are at least four or five such investigations in progress.

As a state institution it becomes essential for us to safeguard the work which we do and in all of our coöperative investigations we reserve absolute proprietorship in the results obtained and the rights to publish them.

The Engineering Experiment Station now expends approximately $50,000, but as this must be divided among nine or ten different departments, it thus gives only a small sum to each. It is my hope that each one of our men who is a specialist in his particular line may have the opportunity to direct a special corps of investigators, thus developing scientific knowledge to a point where it would be helpful to industries, and through the accumulation of large sums of money, enabling us to do work on a scale which is not possible for any college, no matter how magnificent that may be. If I can secure the coöperation of the industries of Illinois, I have little doubt but that it will be accomplished.

Charles H. Benjamin.[3] The Engineering experiment station at Purdue is an infant but two years old, but it is a very lusty infant, alive and kicking. We now have a paid staff of workers, and a very good field in which to work, and our future is still before us. Our object in establishing the station was primarily to

[3] Dean, Purdue University, Lafayette, Ind., Mem. Am.Soc.M.E.

coördinate the research work which has been carried on at Purdue for so many years, and to enable us to do it more satisfactorily, and to publish the results more widely. Another purpose in forming this organization in coöperation with the industries of the State is that primarily we are interested in Indiana, its products, its manufacturers, and its future, and it is going to be our first aim to collaborate with the men of Indiana to increase this productiveness. There is a certain advantage in a university laboratory. A university laboratory or engineering experiment station has no particular axe to grind, and this removes it from any suspicion of commercial interest. Sometimes we are required to investigate problems that perhaps could be better investigated by the private concerns but that establishment feels that its own efforts would be misinterpreted, and that the results from the engineering experiment station will receive more universal credence and support. The organization, and our methods of work, are very similar to those which Dean Richards has so well outlined. The time is too short to tell of the things that we are doing and expect to do. I will only mention one or two. One is the testing of road materials and the coöperation with the highway commissioners in the building of good roads. Another is the efficiency of the carburator. One of the most important however, of our investigations, is that of the farm tractor, in which we are coöperating with the agricultural school of the university. We expect to see a testing plant at the university which will bear somewhat the same relation to the farm-tractor proposition as the locomotive laboratory does to the problems of the railroad, and our only difficulty is to take care of the amount of work which it brings, and which comes to us without solicitation.

In conclusion, I wish to express my appreciation of the work of the research committee. I do, however, want to urge caution, not on the part of this committee, but on the part of perhaps some governing agencies in trying to shape research work. The research man is a genius. He is born, not made. He is peculiar and he must work in his own way and on his own initiative. He must not be interfered with, and he must be allowed to follow a thing in his own way.

J. R. Bibbins,[1] as chairman of the Chicago Section of the Research Committee, offered the following resolution:

Whereas, it is a matter of generally accepted concern that any advanced policy of the American Society of Mechanical Engineers, in common with other complementary learned societies and associations, should incorporate prompt and extended recognition of scientific and industrial research as a specific means of advancing technology and proper industrial development of the nation; and,

Whereas, the Great War has fully demonstrated the principle of research, applied broadly as well as in detail, to be of inestimable benefit in advancing national welfare; and,

Whereas, the Committee on Aims and Organizations has specifically recommended that the American Society of Mechanical Engineers take a more active interest in this field; therefore, be it

Resolved, That it be declared the sense of this research session of the A. S. M. E., that Engineering Council shall be encouraged to undertake active support of a plan and organization of scientific and industrial research to the end that the following objects may be accomplished with all reasonable dispatch:

1 To secure the passage in the present Congress of a special act furthering nation wide research in State units through congressional appropriations for this purpose under the general coördination of Engineering Council, or other national agency thoroughly representative of the engineering profession.

2 To encourage trade, industrial, and utility associations to interest themselves in the advance of the Arts and the constructive benefits to be derived from research work in their respective fields and to coöperate with them in their efforts in these directions.

3 To encourage the various research institutions or instrumentalities now or to be established by the Federal and State governments in their close coöperation in this general research policy.

4 To encourage and assist in the establishment of organized departments of engineering research at the various universities, adequately equipped with material and personnel and to bring such department as closely as possible in touch with the vital problems of industrial development confronting the Nation.

5 To institute organized publicity with the industries of the country and ascertain broadly by a thorough canvass their vital needs, with a view to directing the research work of the country and the coöperative development of the industries through the agency of the technical laboratories both public and private.

6 To organize and support a separate department of the societies activities, in close coöperation with similar departments of other technical societies, to act, through Engineering Council, or other representative national agency, as a permanent clearing house for all research work.

On presenting this resolution Mr. Bibbins stated that while there has been a considerable amount of discussion as to the propriety of state institutions undertaking work of this character he firmly believed in the necessity of each state developing itself as a unit. "They cannot do too much," he declared. "We should encourage by all possible means, every form of intelligent and efficient research. We do not disparage in the slightest degree purely scientific research and we recognize the absolute necessity of it. At the same time we also recognize the equal necessity of research in the more practical phases of the research work.

"The industries want men. They already have the money in abundance. Their executives are keen in search of improved materials, methods, and processes. If successful, the product instantly becomes better and cheaper. Many of the larger industries are alone spending millions for research of such a character as adapted to their essentially commercial undertakings. But what of the lesser industries? They have not the means to maintain expensive research laboratories, nor perhaps the vision to see the need of them, although it is these very industries that are most in need of encouragement. Where, then, may we find a solution of this modern pressing need?

"The answer seems to be in that agency that will produce men of vision, ability and perspective. These men are produced at the seats of learning, whose academic influence is admittedly nation-wide. They are usually supported by the State and indirectly through taxation by the industries. Yet for some reason, the impression of academic limitations still prevails in industry, although this is being gradually broken down by the splendid work of unselfish pioneers in technical learning who have given of themselves to obliterate the unfortunate impression.

"What can the A. S. M. E. do to secure recognition, establishment and support of a broad, nation-wide foundation for industrial research? The answer of the Chicago Research Committee, as far as present formulated, is found in the foregoing resolution, which is purposely suggestive and submitted to the Detroit Convention in the hope that concrete action will result."

Following Mr. Bibbins' presentation of the resolution offered by the Chicago Committee, there was a general discussion which centered around the question of governmental supervision of reasearch. The resolution was first discussed by Dean A. A. Potter, who stated that while he believed The American Society of Mechanical Engineers should encourage reasearch, and while it is unquestionably the purpose of the Society to urge governmental recognition, it would nevertheless be a mistake to approve a resolution asking Congress to appropriate a certain amount of money to support research in certain types of institutions. He believed that The American Society of Mechanical Engineers should express its approval of all kinds of scientific and industrial research, but should not approve any specific bill.

Doctor Mees, Director of the Eastman Kodak Research Laboratory, then took the floor and stated that he was in accord with Dean Potter's remarks and did not believe in urging Federal research. It was a question whether Federal research was desirable. The leaders of industry were against it, and the advice that he would give to the Society—he was not a member of it—was to pay for its own research.

Several members of the Society who favored financial assistance on the part of the Government next presented their views and urged that the Society endorse any measure which would obtain an appropriation from the National Government for the benefit of such institutions as might be selected.

C. H. Bierbaum also discussed the resolution. A bill of the kind proposed was proper enough from a theoretical point of view, but from a practical point of view he did not believe anything worse could be done than to have Congress pass a bill for Federal research, for there would then be a most inefficient distribution of

Suggested Formula for Rating Kerosene Engines

This and the Following Paper on Standards of Carburetor Performance, Together With the Discussion at the Gas Power Session of the Spring Meeting, Form a Timely Presentation of Subjects Dealing With Standardization of Internal-Combustion Engines

By D. L. Arnold,[1] Chicago, Ill.

At the present time there is no standard method of rating kerosene oil engines, and consequently engines of the same displacement are given different ratings by each manufacturer. A standard formula might therefore be of value and in this paper the writer discusses the various formulæ now in use and suggests that a piston displacement of 13,000 cu. in. per minute be taken as one brake horsepower. The subject of a standard nameplate is also discussed and a suggested form is given.

Among the various companies manufacturing kerosene engines there seems to be no uniform standard of rating in use, and as a result engines of the same bore, stroke and speed—or in other words, of the same piston displacement per minute—are given different ratings by almost as many manufacturers. In the past little attention has been paid to this minor detail, as it seems to have been considered, but the purchaser of engines and tractors has had much experience with this inconsistency. For instance, one buys an engine of 4 hp. that will actually develop 6.5 hp.; another buys one also rated 4 hp. but it will only develop 5 hp., and it will in all probability have a different piston displacement per minute. Apparently this means nothing as far as the customer is concerned, for in each case he receives more horsepower than he believed he was purchasing. A very great difficulty does arise, however, when these engines are judged by the amount of maximum work which they will perform in a given length of time, not on brake tests but on users' equipment, and the result is that the purchaser of the smaller engine is greatly dissatisfied, despite the fact that his engine will develop a 25 per cent overload.

TABLE 1 FORMULÆ NOW IN USE FOR FOUR-STROKE-CYCLE ENGINES

D = diameter of piston, in. L = length of stroke, in.
n = number of cylinders N = number of revolutions per minute

No.	Authority	Formula
1	N.A.C.C.[1] or A.L.A.M.	$\frac{D^2n}{2.5}$ (at 1000 ft. per min.)
2	E. P. Roberts	$\frac{D^2LNn}{18,000}$
3	French Automobile Club	$0.45\ D^2n$ (at 985 ft. per min.)
4	Royal Automobile Club, British	$0.405\ D^2n$
5	Royal Automobile Club, Swedish	$\frac{D^2LNn}{15,240}$
6	Prof. H. L. Collanders	$0.565\ D(D-1)n$
7	T. Thornycrofts	$\frac{D^2L^{0.75}n}{2700}$
8	M. Faroux	$0.121\ D^{2.4}L^{0.6}$
9	M. Arnon	$0.1\ D^2n$
10	E. W. Roberts[2]	$\frac{D^2LNn}{X}$

[1] Vol. 1, p. 30, S.A.E. Standards Data Sheets.

[2] Gas Engine Handbook, p. 131. X is a factor varying with the fuel and cycle. For 4-cycle engines X equals 16,000 for natural gas and 14,000 for gasoline.

The foregoing is only a sample case of the inconsistency which has resulted in many bills now being introduced, or about to be introduced, in state legislatures, specifying how an engine shall be rated. If these bills should all pass it might be that each state would reqnire a different rating, and thus the manufacturers would be obliged to furnish a different nameplate in each state. It would therefore seem advisable for the manufacturers to get together and adopt a standard rating for kerosene engines. If standard rating is to be of service, it must give equal protection to the manufacturer and the customer, and any formula which is obtained must therefore be based upon practice covering a sufficient period of time. Before taking up the proposed formula, however, the writer wishes to review some of the formulæ that are in use today and which are listed on Table 1.

Formulæ Now Used for Four-Stroke-Cycle Engines

The A.L.A.M. formula[1] is based on the assumption that there is developed within the cylinder a mean effective pressure of 90 lb. per sq. in., that the engine operates with 75 per cent mechanical efficiency, and that the piston speed is 1000 ft. per min. With ungoverned engines this formula is perhaps as good as any, but for engines operating with governors it is obvious that if a piston speed of other than 1000 ft. per min. is maintained, it will be necessary to make a correction to cover this point, in which event the formula is unwieldy and inconvenient.

An empirical formula[2] which is considered as very conservative practice when compared with the various ratings now used by engine manufacturers is as follows: B.hp. $= 0.00006042\ D^2LNn = V/13,000$. Before deriving this formula the writer compared the

Presented at the Spring Meeting, Detroit, Mich., June 1919, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

[1] Chief Engineer, Gas Power Engineering Dept., International Harvester Co., Chicago, Ill.

[1] Derivation of A.L.A.M. Formula:

Let HP_b = brake horsepower
HP_i = indicated horsepower
HP_r = rated horsepower
A = area of piston, sq. in.
D = diameter of piston, in.
E = mechanical efficiency (assumed at 0.75)
L = length of stroke, in.
n = number of cylinders
P = mean effective pressure, lb. per sq. in. (assumed at 90 lb.)
V = piston displacement per minute, cu. in.
N = revolutions per minute
s = piston speed, ft. per min. (assumed at 1000)

$$HP_b = HP_i \times E = \frac{1}{4}\ \frac{PAsNn}{33,000}\ E = \frac{90 \times 0.7854\ D^2 \times 1000 \times n \times 0.75}{4 \times 33,000 \times 12}$$

$$= \frac{D^2n}{2.489}, \text{ or for practical purposes, } \frac{D^2n}{2.5}$$

Also, since $s = \frac{2LN}{12}$

$$HP_b = \frac{90 \times 0.7854\ D^2 \times 2LN \times n \times 0.75}{4 \times 33,000 \times 12} = \frac{D^2LNn}{14,939} = 0.00006693\ D^2LNn$$

and substituting V for $0.7854\ D^2LNn$

$$HP_b = \frac{90 \times V \times 2 \times 0.75}{12 \times 33,000 \times 4} = \frac{V}{11,733}$$

[2] Derivation of Empirical Formula:

$$HP_r \text{ (recommended)} = \frac{0.7854\ D^2LNn}{13,000} = \frac{V}{13,000}$$

$$HP_r \text{ (transformed)} = \frac{D^2LNn}{16,550} = 0.00006042\ D^2LNn$$

ratings of 115 engines manufactured by 61 companies and found them to vary from 8,256 to 19,985 cu. in. per b.hp. Forty-six engines were rated using 11,000 cu. in. or less as 1 b.hp.; 29 used 11,000 to 12,000 cu. in.; 12 used 12,000 to 13,000 cu. in.; 10 used 13,000 to 14,000 cu. in. and 18 used above 14,000 cu. in.

It will thus be seen that 87 engines or approximately 75 per cent were rated as using less than 13,000 cu. in. per b.hp. and while this value may be more conservative than some manufacturers might wish to use, it gives a standard basis of comparison and allows the engine to develop a fair percentage of overload above its rating, since any engine should be able to develop as a maximum 1 b.hp. per 11,000 cu. in piston displacement per min. when the engine is in good condition.

At this time it seems desirable to compare this new formula with those already in use, and for that reason Table 2 has been compiled. It should be noted, however, that the table does not show the maximum horsepower that can be expected from an engine but has reference only to the rated brake horsepower which should be reasonably expected. If one engine can develop a higher maximum than another, or, in other words, can make good on a lower piston displacement per minute than its competitor, the credit is certainly due to the manufacturer who can consistently produce these conditions. However, practically all engines of correct design will develop a maximum horsepower according to the formula heretofore given, namely 1 b.hp. per 11,000 cu. in. piston displacement per minute.

TABLE 2 COMPARISON OF ENGINE-RATING FORMULAE

Formula No.	Authority		Expressed in piston displacement per minute	Expressed in terms of Roberts formula
1	N.C.C.C. or A.L.A.M.		$\frac{V}{11,733}$	$\frac{D^2LNn}{14,939}$
2	E. P. Roberts		$\frac{V}{14,137}$	$\frac{D^2LNn}{18,000}$
3	French Automobile		$\frac{V}{13,180}$	$\frac{D^2LNn}{16,781}$
5	Royal Automobile Club, Swedish		$\frac{V}{11,969}$	$\frac{D^2LNn}{15,240}$
10	E. W. Roberts	16000	$\frac{V}{12,566}$	$\frac{D^2LNn}{15,999}$
		14000	$\frac{V}{10,995}$	$\frac{D^2LNn}{13,998}$
		11500	$\frac{V}{9,032}$	$\frac{D^2LNn}{11,499}$
11	Rated Horsepower Recommendation		$\frac{V}{13,000}$	$\frac{D^2LNn}{16,550}$

With reference to the rating of four-stroke-cycle engines, it would seem best for all concerned that this rating should be made the nearest whole horsepower to that determined by the standard formula, it being a very easy matter to change the rated speed of the engine in order to accomplish the exact rating. In any event, however, the rated horsepower would not, if the foregoing condition is adhered to, vary more than plus or minus 0.5 hp.

Tractor-Engine Nameplates

Having established a standard rating for this class of engine, there should also be a standardized nameplate; to state the horsepower alone with no reference to speed is insufficient and misleading. This nameplate should be clear and concise, leaving no cause for doubt as to what is meant.

In considering the internal-combustion-engine rating we must also consider the tractor rating as the internal-combustion engine forms its power unit and the tractor rating is therefore dependent upon the engine rating. The owner of a tractor is not only interested in the amount of power that can be delivered by the engine but also in the amount that can be delivered to the drawbar at the different speeds. Here again, however, manufacturers have been inconsistent in the ratings which they have made. The majority of manufacturers have followed the rule that drawbar horsepower should be considered as 50 per cent of the rating of the power unit and in actual practice covering many years of experience this seems to be a very conservative figure to use. It is true that the tractor will often develop greater drawbar horsepower, but when taking into consideration the wide range of conditions through which the tractor must work, such as changes of soil and class of work, a 50 per cent rating for the drawbar pull seems on the whole to be the best value to use; therefore, on the tractor engines it would seem that the best nameplate would be one like that given above.

> 16 Brake HP at 500 RPM
> 8 Drawbar HP at 500 RPM of the engine
> Drawbar pull:
> —— lb., reverse speed at —— miles per hour
> —— lb., first speed at —— miles per hour
> —— lb., second speed at —— miles per hour
> —— lb., third speed at —— miles per hour
> Drawbar pull and HP are on the average good footing.

Formulæ Best Adapted to Rating Engines and Tractors

The following formulæ are those which it would seem are best adapted to the rating of internal-combustion engines and tractors:

$$\text{Rated engine horsepower} = \frac{0.7854\, D^2LNn}{13,000} \quad \ldots\ldots [1]$$

$$\text{Drawbar horsepower} = \frac{HP_r}{2} \quad \ldots\ldots [2]$$

$$\text{Drawbar pull,}^1 \text{ lb.} = \frac{375 \times HP_d}{S} \quad \ldots\ldots [3]$$

$$\text{Motor torque,}^2 \text{ in-lb.} = \frac{63,025.21 \times HP_b}{N} \quad \ldots\ldots [4]$$

Practical work in experimental testing laboratories and on regular test floors has proved that four-stroke-cycle engines operating on kerosene will develop for periods of two hours or more 1 b.hp. per 11,000 cu. in. piston displacement per min. and a few engines have for short periods of time developed 1 b.hp. for every 9800 cu. in. piston displacement per min. Therefore, making allowances for general wear, mishandling and improper adjustment, the four formulæ given in the preceding paragraph will be seen to be conservative and well adapted for the rating of this type of engine.

---

[1] Derivation of Drawbar Pull Formula:

Let F_d = drawbar pull, lb.
HP_d = drawbar horsepower
S = speed in miles per hour

$$\text{Then } F_d = \frac{HP_d \times 33,000 \times 60}{5280 \times S} = \frac{375\, HP_d}{S}$$

[2] Derivation of Motor Torque Formula

Let HP_b = brake horsepower
l = length of brake arm, in.
W = lb. pull at end of arm
N = revolutions per minute
T = motor torque, in-lb.

$$\text{Then } HP_b = \frac{2\pi\, lNW}{33,000}$$

$$T = \frac{HP_b \times 33,000 \times 12}{2\pi N}$$

$$= \frac{63,025.21 \times HP_b}{N}$$

Standards of Carburetor Performance

By O. C. Berry,[1] Lafayette, Ind.

The type of test which a carburetor is most frequently given to establish its merit or lack of merit is carried out in the following manner: An engine in good mechanical condition is tested, using a carburetor which bears a high reputation. These tests are then repeated, using the new carburetor, and its merits are thus reported in terms of the comparative performances of the engine. The results of these tests are valuable and convincing, and while they will always be the final criterion of carburetor performance, they fall a little short of the ideal in that they fail to show the reasons for the differences. Several writers have recently pointed this out and suggested that the performance of a carburetor should also be expressed in terms of its ability to perform those functions which are essential to proper carburation. In order to do this it will be necessary to determine these essentials. This is a difficult task, but its accomplishment should prove of great benefit. In this paper a list of the essential factors, as now understood, has accordingly been made and some experimental data are also presented which it is hoped will help to establish certain of the standards of performance.

Satisfactory carburation of a liquid fuel depends jointly upon the carburetor, the intake manifold, and the temperature of the combustion-chamber walls. These parts may therefore be considered the carburating apparatus and the headings under which are grouped the tests to determine the degree of excellence with which each of these parts performs its respective functions may all be listed together. These headings, expressed in the general order of their importance, are as follows:

a The range of flow-rate capacities, or, in other words, the maximum and minimum number of cubic feet of air per minute that can be handled

b The richness of the mixture as affected by: the rate of flow of the air through the carburetor; sudden changes in the rate of flow; the amount the throttle is open

c The pressure drop through the carburetor at different rates of flow

d The thoroughness and uniformity with which the fuel and air are mixed

e The uniformity of the richness of the mixture furnished to the different cylinders

f The temperature and dryness of the mixture entering the cylinders

g The temperature of the combustion-chamber walls, particularly the piston head.

The relative importance of these items is largely a matter of opinion and will be different under different conditions. For example, the capacity for handling large amounts of air is much more important in passenger cars than in trucks and tractors, while in tractors using kerosene the temperature of the mixture and combustion-chamber walls becomes comparatively much more important than it is in passenger cars burning gasoline.

Items To Be Investigated

Range of Flow-Rate Capacities. In passenger-car engines great importance is attached to flexibility, and the buying public would not consider a car that was notably defective in this respect. The power developed by an engine varies almost directly with the weight of air used per minute, and the carburetor must therefore be able to supply this air, properly mixed with fuel, through a wide range of flow rates.

The passenger car is expected to idle down to one or two miles per hour on high gear and at the same time have a maximum speed capacity well above 50 miles per hour. Few carburetors are capable of furnishing a proper mixture over so wide a range, although most carburetors are sold under claims of wonderful flexibility.

A carburetor is truly suited to an engine only when its flow-rate capacities correspond to the requirements of the engine, and this condition will be attained with the greatest certainty when the requirements of the engine and the capacities of the carburetor are both given in cubic feet of air per minute. It is therefore suggested that the flow-rate capacities of all carburetors should be stated definitely in cubic feet per minute, and that this information should always accompany the statement of the size of the carburetor flange.

With the carburetor adjusted so that the engine carries its full torque with open throttle, the air required per brake horsepower per minute will remain nearly constant irrespective of the amount of gasoline used or the speed of the engine. For the usual passenger-car type of engine with compression ratio of about 4 to 1 this constant is about 2.1 cu. ft. per min. at full power, and seldom exceeds 2.3 cu. ft. per min. The air used when idling at any speed is almost exactly one-quarter of that used under full load at the same speed. With these data, which are based upon the performance of the engines tested at Purdue, it is easy to compute the air requirements for any engine of the same type, for any torque and any speed.

Richness of the Mixture. The thermal efficiency of an engine at any speed and load is affected more by the richness of the explosive mixture than by any other factor. It is therefore highly important that the carburetor deliver the mixture to the engine in the proper proportions, at all speeds and loads. The richness of mixture giving the best power and the one giving the best efficiency must each be experimentally determined for various speeds and loads, so as to learn what effect a change in either will have on the mixture requirements of the engine. The temperature and the dryness of the mixture must also be varied to determine whether or not they affect the power or efficiency of the engine.

In the Purdue tests the richness of the mixture is expressed in pounds of gasoline per pound of dry air. With a dry mixture at half load and 1000 r.p.m., regular firing may be obtained with mixtures between 0.0575 and 0.12. The best efficiency under the same conditions accompanies a mixture of about 0.067, and the best power, 0.08. The method used in obtaining these results and a few of the characteristic curves will be presented at the end of this paper.

Pressure Drop Through the Carburetor. It is always necessary to have the gasoline in the float chamber of the carburetor at a lower level than the delivery orifice in order to prevent overflowing when the engine is not running, and the suction in the carburetor must be great enough to overcome this safety head before any gasoline will be delivered. The best attainable condition, therefore, will be to have just enough vacuum in the carburetor to cause a satisfactory flow of fuel and air, and no more. Because of the influence of volumetric efficiency on engine capacity the importance of a small carburetor vacuum is very great.

Thoroughness of the Mixing. The thoroughness and uniformity with which the fuel is mixed with the air is important. One of the greatest helps in reducing the fuel to a gas is to atomize it thoroughly and mix it with the air. This gives the fuel a large amount of exposed surface and helps to bring all parts of the mixture up to the same degree of saturation.

The mixture in all parts of each individual cylinder must be uniform and the fuel reduced to a gas at the end of the compression stroke or else the combustion will not be complete, thus lowering the power and efficiency of the engine and causing uneven running. Therefore, if the engine runs with a regular and even exhaust, the thoroughness of the mixing is probably good

[1] Professor of Mechanical Engineering, Purdue University.

Presented at the Spring Meeting, Detroit, Mich., June 1919, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and is subject to revision. Copies of the complete paper may be obtained at a nominal cost.

along with all of the other factors influencing engine performance. The best direct test of the quality of the mixing is to have the carburetor discharge into a section containing glass placed between the carburetor and manifold. The best dry mixtures appear as colorless and dry as pure air, while wet mixtures resemble a fog, and in most cases streams of liquid fuel are seen following a spiral path along the walls of the manifold.

Uniformity of Mixture to All Cylinders. The richness of the mixture entering the various cylinders often differs widely, especially when very wet mixtures are used. Some manifold designs also aggravate this condition. The results attained by any given manifold may be tested by removing the exhaust manifold and observing in comparative darkness the flames from the exhaust openings. By adjusting the carburetor for continuously leaner mixtures the impoverished cylinders will be caused to miss, and then by gradually enriching the mixture the yellowish flame will indicate the cylinder with the rich mixture.

Temperature and Dryness of the Mixture. With the rapidly increasing difficulty in vaporizing the commercial liquid fuels, the temperature of the mixture becomes a more and more important consideration. Before the fuel can be burned it must be vaporized, and this requires both heat and time. The mixture should be dry and thoroughly mixed at the end of the compression stroke in order to get good combustion, and the gas temperature should be as low as possible at the end of the suction stroke, in order to keep up the volumetric efficiency. It is therefore desirable to make the fullest possible use of the heat in the combustion-chamber walls, piston head and compression, and to introduce the mixture into the cylinder as wet as possible and still be sure of having it dry before it is burned.

It is possible to compute approximately the change in power that will accompany a definite change in the temperature of the mixture furnished to the engine. The computation is based upon the fact that the density of a gas varies inversely as its absolute

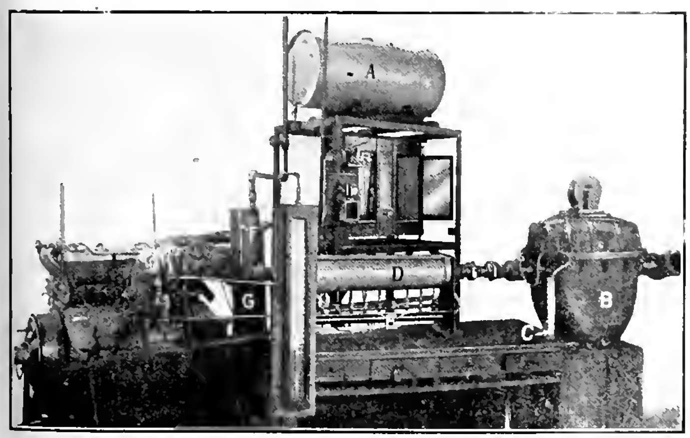

Fig. 1 Willys-Knight Engine and Equipment for Testing Its Carburetor

A, gasoline tank; *B*, air meter; *C*, manometer; *D*, heater; *E*, gas jets; *F*, thermometer; *G*, water tank

temperature. Since the power generated in the cylinder varies almost in direct proportion to the weight per minute of the mixture used, it will vary almost in the inverse ratio of the absolute temperatures of the mixtures. As an illustration, suppose the engine will develop 12.5 hp. when the mixture has a temperature of 250 deg. fahr. What will it develop when the temperature is 60 deg. fahr.? The power times the inverse ratio of the mixture temperatures is as follows:

$$12.5 \times \frac{460 + 250}{460 + 60} = 17.06$$

This indicates that 17.06 hp. is to be expected with the 60 deg. fahr. mixture. As a matter of fact, the temperature in the cylinders at the end of the suction stroke rather than the intake manifold temperature determines the density of the charge, but this temperature cannot be measured. Again, the indicated rather than the brake horsepower is the one that varies with the density of the charge, while the brake horsepower is the one that is usually measured. These are the main reasons why the results obtained are only approximately correct. The figures given are from two Purdue tests run at the same speed with the same throttle orifice, and the power was increased from 12.5 to 16.0 instead of 17.06 b.hp.

The task of determining the best method of introducing into the mixture the heat for vaporizing the fuel is both important and difficult and will require considerable careful experimentation. The Purdue tests with the "hot spot" warrant the conclusion that it is superior to any method of preheating the air, in that it dries the mixture sufficiently at lower temperatures and, therefore, does not decrease the power of the engine so much. These tests also indicate that the design of the hot spot is still in need of experimental development.

Temperature of the Combustion Chamber. When the mixture is dry as it enters the cylinders, or the fuel so well atomized that it remains suspended in the air and is entirely vaporized during the compression stroke, the heat absorbed from the combustion-chamber walls does not improve the carburation, but decreases

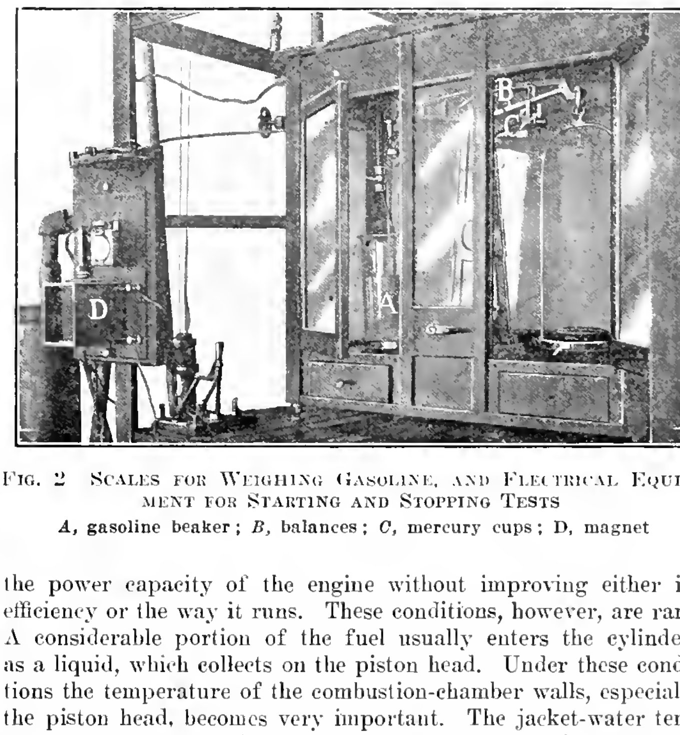

Fig. 2 Scales for Weighing Gasoline, and Electrical Equipment for Starting and Stopping Tests

A, gasoline beaker; *B*, balances; *C*, mercury cups; D, magnet

the power capacity of the engine without improving either its efficiency or the way it runs. These conditions, however, are rare. A considerable portion of the fuel usually enters the cylinders as a liquid, which collects on the piston head. Under these conditions the temperature of the combustion-chamber walls, especially the piston head, becomes very important. The jacket-water temperature should therefore be kept high when the piston head is depended upon to flash any considerable amount of liquid fuel into a gas. This conclusion is borne out by the engine tests. With the air entering the carburetor at 70 deg. fahr. and the jacket water maintained at 110 deg., the engine would not fire regularly with any richness of mixture. When the jacket-water temperature was raised to 200 deg. fahr. the engine would fire some of the richer mixtures regularly, and by raising the air temperature to 80 deg. fahr. the engine developed full power and efficiency and would fire a wide range of mixtures.

The Purdue Tests

The tests at Purdue University were carried out on a Haynes Light Six and a Willys-Knight four-cylinder engine, mounted on a Diehl electric dynamometer. Fig. 1 shows the Knight engine mounted ready for a test. Fig. 2 gives a more detailed view of the scales and the electrical apparatus for starting and stopping the tests. The supply of gasoline is piped from tank *A*, Fig. 1, into a 2-qt. glass vessel placed in one of the scale pans. This is shown at *A*, Fig. 2. In order to give the balances freedom of motion, the gasoline was siphoned from this vessel to the carburetor. The balances *B*, Fig. 2, were capable of weighing the

gasoline to the one-hundredth part of an ounce, and were equipped with wires dipping into mercury cups C, Fig. 2, which completed an electric circuit just when a balance was reached. The hand on the dial of the air meter was equipped with an electrically operated clutch and brake, the stop watch was operated by a strong magnet D, Fig. 2, and the revolution counter on the end of the dynamometer shaft was electrically operated. By these means, when the scales came to a balance they would start the stop watch, the revolution counter and the recording hand on the air meter and ring a gong. Weights corresponding to the gasoline to be used were then removed from the scale pan, and when the scales again came to a balance the recording apparatus was electrically stopped, making it possible to time all of the readings together and make the record at leisure from instruments that were standing still.

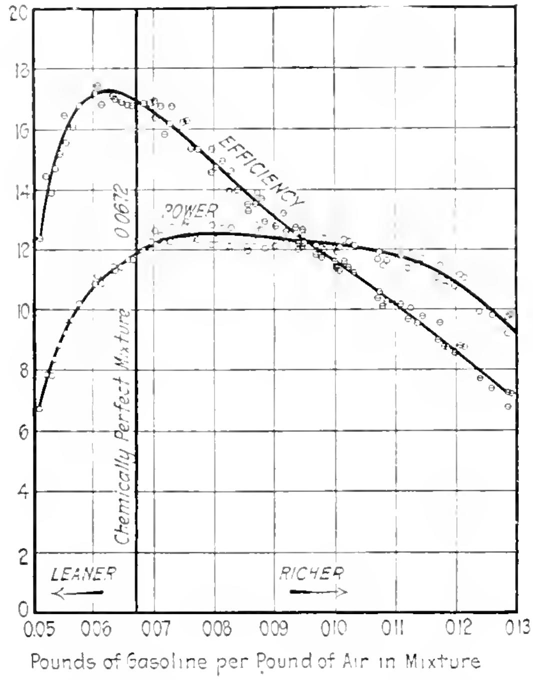

Fig. 3 Power and Efficiency Curves of Willys-Knight Engine

Throttle set for half-load. Speed, 1000 r.p.m. Cooling-water temperature, 200 deg. fahr.

The air was metered through an Emco No. 4 gas meter B, Fig. 1, reading to cubic feet, so that tenths of a cubic foot could be estimated. The drop in pressure through the meter was indicated by the water manometer C, Fig. 1. The barometer and the wet and dry-bulb readings on a hygrometer were taken periodically, so as to be able to determine the pounds of dry air used in each instance.

The meter was connected by rubber tubing to a heater D, Fig. 1, made up of 4 ft. of 3-in. wrought-iron pipe surrounded by an asbestos cylinder with a space between large enough to allow the pipe to be heated by the flames from the gas burners E. The exit air temperature was indicated by the thermometer F whose bulb was exposed directly to the air inside of the pipe. The temperature of the air could be regulated within close limits by careful adjustment of the gas flames. In some instances a section containing glass was inserted between the carburetor and engine, which offered ample opportunity to observe the character and behavior of the mixture inside.

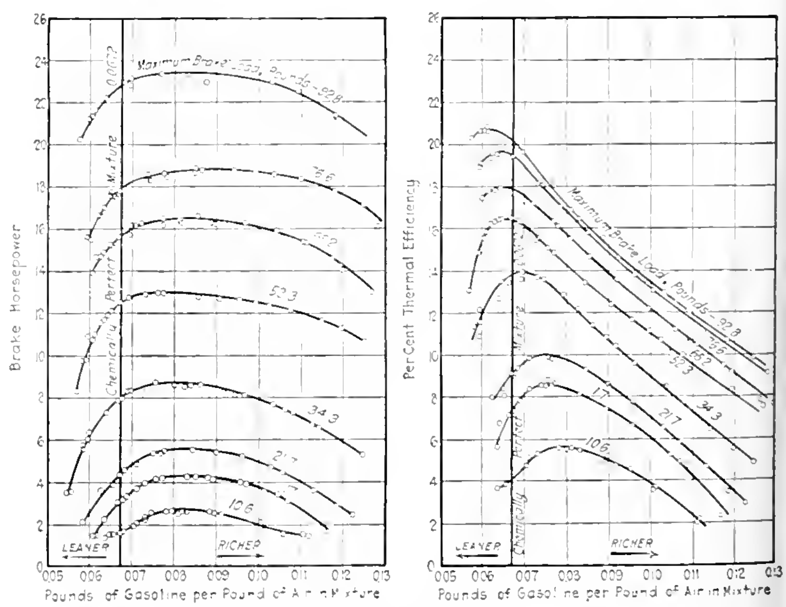
The speed of the engines was read on a tachometer as well as being computed from the stop-watch and revolution-counter readings. The torque developed by the dynamometer was weighed by means of a sensitive set of Fairbanks scales. This is the same as the brake load on the engine, thus making it possible to compute the power developed by the engine to a satisfactory degree of accuracy.

The object of the first series of tests was to determine the effect of changing the richness of the mixture on the performance of an engine. It was planned to determine the mixture that would give the best power, the one for the best efficiency and the range of mixtures that could be fired regularly.

Accuracy of Results

The vertical line in Fig. 3 (at 0.0672) represents the chemically perfect mixture, or the one in which there is just enough oxygen in the air to burn the fuel and no excess of either fuel or air exists. The curves show that the engine will run with a mixture as lean as 0.05 lb. of gasoline per lb. of air, but will not pull well with so lean a mixture. The test log shows that it misses frequently at this power, but that the performance becomes better as the mixture is made richer, until at 0.055 it fires every cylinder regularly. The best efficiency is obtained at 0.063, when the engine is developing 91 per cent of its maximum power capacity with this orifice at 1000 r.p.m. The best power accompanies a mixture of about 0.08, at which point the thermal efficiency has dropped from 17.25 to 14.8 per cent. The richest mixture that can be fired regularly is about 0.1275, but the engine will run with mixtures as rich as 0.135. Nearly full load can be carried with a mixture as lean as 0.065, or as rich as 0.115. In other words, a carburetor can be adjusted with as lean a mixture as can be used to carry full load and the amount of gasoline can be nearly doubled without greatly affecting the power developed or the smoothness of running of the engine.

In applying the information obtained from these tests to other conditions it must be remembered that these results are for half-load at 1000 r.p.m. when a warm mixture was used that was dry as it left the intake manifold. Before applying the conclusions to other conditions, one must learn the effect of the load carried, the speed and the temperature and dryness of the mixture upon the mixture requirements, power and efficiency of an engine.



Figs. 4 and 5 Power and Efficiency Curves of Willys-Knight Engine

Throttle set for various loads. Speed, 1000 r.p.m. Temperature, air to carburetor, 150 deg. fahr. Cooling water temperature, 120 deg. fahr.

Effect of Load Upon Mixture Requirements

Figs. 4 and 5 show the power and efficiency curves taken from the Willys-Knight engine running at 1000 r.p.m., but with different throttle orifices. During these tests the temperature of the air entering the carburetor was kept at about 150 deg. fahr., and the cooling water at about 120 deg. fahr. This was true of all of the curves excepting the one for 92.8 lb., in which case the mixture was heated up to 125 deg. fahr. in a "hot spot" and the

cooling-water temperature was 160 deg. fahr. Fig. 4 shows that the mixture giving the best power at a fixed throttle setting does not vary with the brake load carried, but remains constant at about 0.08. At light loads the engine will not operate well with as wide a range of mixtures as it can use when carrying more nearly its full capacity. Fig. 5 shows that with light-load throttle settings the mixtures for best power and best efficiency tend to coincide, but as the brake load is increased the mixture for best efficiency becomes continuously leaner, until at full load it is 0.062. In the case of the higher brake loads the engine will hit regularly and run smoothly with the lean mixtures which give the high efficiencies, but the power developed is reduced considerably below the highest attainable at that throttle setting. The most satisfactory mixture for general use at or near full load will therefore be approximately 0.067, giving almost full power and nearly the best efficiency. For higher pulling conditions the mixture had better be caused to approach 0.08, the one for best pulling.

Effect of Speed Upon Mixture Requirements

In Fig. 6 is shown a set of curves taken from tests on the Haynes Light Six engine. The curves show that the mixture giving the best power is not noticeably affected by changes in speed, but that at high speeds the engine cannot hold up its power with quite as much excess fuel as at lower speeds. The data sheets show that the mixture for the highest efficiency also remains unchanged.

Effects of Changing Air Temperatures

Figs. 7 and 8 show a series of curves taken from the Willys-Knight engine with air furnished to the carburetor at temperatures varying from 80 to 275 deg. fahr. They show that 80 deg.

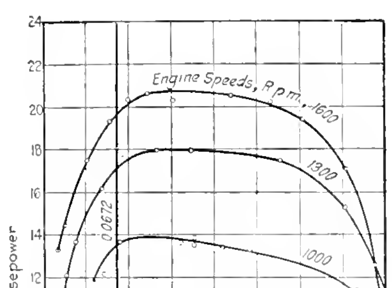


FIG. 6 SPEED CURVES OF HAYNES LIGHT SIX ENGINE
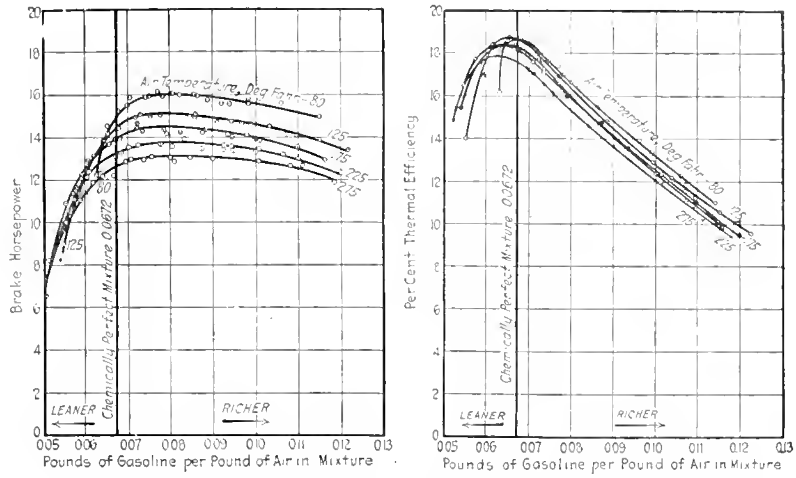
Throttle set for half load. Temperature, air to carburetor, 100 deg. fahr. Cooling-water temperature, 130 deg. fahr.

fahr. air gives the most power and the best efficiency, but that at so low a temperature the engine is unable to use the lean mixtures. Each increase in the air temperature decreases the power of the engine. Up to 150 deg. fahr. the ability of the engine to use the lean mixtures also increases. From 150 to 300 deg. fahr. air temperatures the engine develops its best ability to hit regularly and run smoothly with the lean mixtures, firing every cylinder with a mixture as lean as 0.055. Fig. 8 gives the efficiency curves. The best efficiencies at 80 and 125 deg. fahr. are nearly exactly the same, 18.75 per cent, but at 80 deg. fahr. it accompanies a mixture slightly richer than for 125 deg. fahr. Each increase in temperature between 125 and 275 deg. fahr. decreases the efficiency slightly. At 150 deg. fahr. the mixture for the highest efficiency reaches its leanest point, 0.063, and remains the



FIGS. 7 AND 8 HEATED-AIR TEST CURVES, WILLYS-KNIGHT ENGINE
Throttle set for half load. Speed, 1000 r.p.m. Cooling-water temperature, 200 deg. fahr.

same up to 275 deg. fahr. The effects of increasing the temperature of the air entering the carburetor above 80 deg. fahr. are therefore to decrease the power capacity of the engine considerably and its efficiency slightly, but to make it fire regularly when using leaner mixtures.

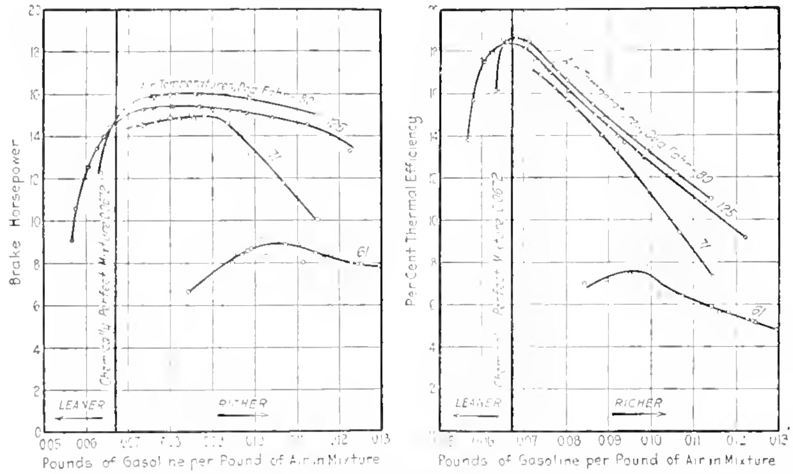
Figs. 9 and 10 show the curves for the same series of tests, but with colder air temperatures. Fig. 9 shows that with an air temperature of 61 deg. fahr. the engine could use only the comparatively rich mixtures and its power capacity was greatly reduced. When the air temperature was increased to 71 deg. fahr. the power was brought nearly up to maximum, but still the engine could not fire the leaner mixtures with regularity. Fig. 10 shows that the efficiency for the 61 deg. fahr. air is very poor, while the 71 deg. fahr. air was much better but the engine stopped before it reached a lean enough mixture to give the best results. It may therefore be seen that 80 deg. fahr. is about the lowest temperature at which the air may be drawn into a carburetor when using Red Crown power gasoline, to get good carburation in an engine having a 200 deg. fahr. cooling-water temperature. If the cooling-water temperature is lowered the temperature of the air will have to be raised correspondingly, while raising the quality of the gasoline will improve the performance with cold air, cool water or both.

The Hot-Spot Tests

Figs. 11 and 12 show curves taken from the Willys-Knight engine using a "hot spot" between the carburetor and the intake manifold. This hot spot was designed to flash the liquid fuel into a gas while heating the air as little as possible. The curves show that by using the hot spot the engine is able to fire the lean mixtures without in turn lowering either its power or its efficiency. The explanation is that the factor controlling the power of the engine is the weight of air that can pass through the throttle orifice in a given time. The air always being cold when it passes this point, the power is not affected by the heat. This is always true for a throttled condition, but as the throttle is opened and the manifold or valves become the limiting factors in the production of power, the advantage of the hot spot decreases, but it does not disappear. It is therefore clear that the method of introducing heat into the mixture by means of a hot-spot is superior in every way to the hot-air method, and particularly so when the engine is throttled down.

Conclusions

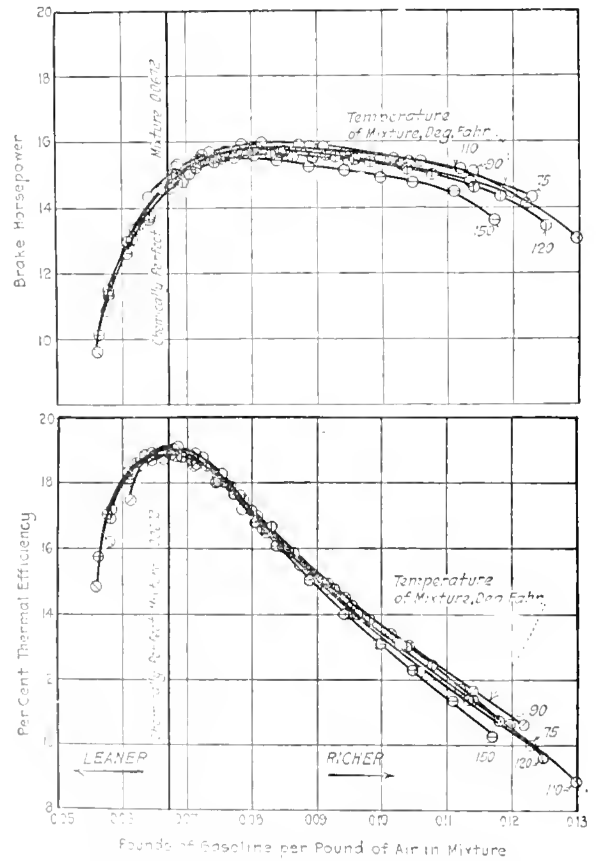
It may be well to again point out the importance of judging the merit of a carburating system in terms of the degree of thoroughness with which the system performs those functions which



Figs. 9 and 10 Cold-Air Test Curves, Willys-Knight Engine

Throttle set for half load. Speed, 1000 r.p.m. Cooling-water temperature, 200 deg. fahr.

are necessary to proper carburation. It is hoped that a discussion of the topic will result in establishing specifications for these tests, and that many may join in the task of carrying out the experi-



Figs. 11 and 12 "Hot Spot" Test Curves, Willys-Knight Engine

Throttle set for half load. Speed, 1000 r.p.m. Cooling water temperature, 200 deg. fahr.

ments that will determine the standards of performance in each case. Tests are needed showing the richness of mixture that will give the best power and the one for best efficiency when using liquid fuels other than gasoline. It would also be interesting to extend the gasoline tests to include wider ranges of speed and higher compression.

The problem of determining the best method of introducing into the mixture the heat necessary to vaporize the fuel is one of great importance, especially in connection with the heavier fuels. As a part of this problem it will be interesting to determine the actual temperatures found in the metal of the piston head and cylinder walls of automobile, truck and tractor engines, and how these temperatures affect the carburation.

The fullest discussion of these problems and the methods employed at Purdue in attacking them is earnestly solicited, and any suggestions in connection with carrying out this line of investigations will be received most gratefully by those in charge of the Purdue Engineering Experimental Station.

Acknowledgments

The experimental work presented in the foregoing paragraphs was carried out in the laboratories of Purdue University under the direction of the Purdue Engineering Experiment Station, and has received throughout the personal attention and encouragement of Prof. G. A. Young, Head of the School of Mechanical Engineering. Most of the tests were carried out and the computations made by Mr. C. S. Kegerreis, Research Assistant. It is hoped that the Experiment Station will have a bulletin on carburation ready for distribution by early winter, and it is planned to present in this bulletin a detailed report of the work which has been summarized in this paper, and also to include such other data as are then available for publication. When available, copies of this bulletin may be obtained by addressing C. H. Benjamin, Director of the Engineering Experiment Station, Purdue University, Lafayette, Indiana.

Although there is scant information on the service and cost of treated roof timbers in cotton mills, paper mills, and other buildings where high humidity causes rapid decay, a number of preservative treatments which it will undoubtedly pay to use may be suggested.

The steeping process consists merely in soaking the timber in a water solution of a preservative such as zinc chloride, sodium fluoride, or mercuric chloride. The wood must be thoroughly seasoned. It is left in the solution 1 day for each inch in thickness and 1 additional day. After treatment, the timber should be air dried before using. Specific directions for the use of this process (and they are especially necessary for handling mercuric chloride) may be secured from the Forest Products Laboratory, Madison, Wis. Zinc chloride attacks lead paints, but is very desirable otherwise. Mercuric chloride is very effective, but is poisonous and has a decided corrosive action on steel, so that steel tanks cannot be used with it. Sodium fluoride does not attack paint, is not corrosive, and in most other respects is very desirable.

Timbers may be coated with coal-tar creosote by a brush treatment, by dipping in hot oil for 5 to 15 minutes, or the hot- and cold-bath method. This last method consists in submerging the lumber in hot oil for several hours and then either allowing the oil to cool down slowly with the wood in it or plunging the wood into cool oil and leaving it for several hours.

Although pressure treatments are the most expensive, they are the most effective because they result in the greatest absorption and penetration of preservative. Roof planking should receive 8 to 12 lb. of creosote per cubic foot, or 0.5 lb. of the salt if zinc chloride is used. Such treatment should add at least 20 years to the life of roof plank.

Whenever it becomes necessary to cut into treated timber, the untreated wood exposed by cutting should be given two brush coats of creosote or some other preservative.—Technical Notes No. A-3, Forest Products Laboratory, U. S. Forest Service, Madison, Wis.

DISCUSSION AT GAS POWER SESSION OF SPRING MEETING

THREE papers were read and discussed at the Gas Power session of the Spring Meeting, held on the morning of Wednesday, June 18, under the auspices of the Sub-Committee on Gas Power, Prof. W. T. Magruder presiding. The titles of the papers were: Crude Oil Motors versus Steam Engines in Marine Practice, by J. W. Morton; A Suggested Formula for Rating Kerosene Engines, by D. L. Arnold; and Standards of Carburetor Performance, by O. C. Berry. Mr. Morton's paper appeared in the July issue of MECHANICAL ENGINEERING (p. 609) and consisted of a discussion of the various factors to be considered in choosing the form of motive power for war vessels and cargo ships, together with a presentation of the advantages as compared to steam engines of high- and low-powered oil motors of both the constant-pressure and constant-volume type. The relative values of four-stroke cycle, two-stroke cycle, double-acting, and horizontal oil motors were also compared and some details of their construction such as lubrication systems, piston cooling and scavenging pumps were analyzed. The papers by Messrs. Arnold and Berry will be found elsewhere in this issue.

DISCUSSION OF MR. MORTON'S PAPER ON CRUDE-OIL MOTORS VS. STEAM ENGINES IN MARINE PRACTICE

LOUIS ILLMER[1] (written). In the paper under discussion, Mr. Morton apparently favors the four-stroke oil engine and appears to give insufficient credit to the recent advances made in heavy-duty two-stroke engine design as applied to the merchant-marine service.

Undue complication of mechanism is probably chiefly responsible for the slowness on part of the American shipbuilder in adopting the oil engine for the propulsion of large cargo ships, since each additional vital moving part adds to the first cost, the liability to accident and the overhauling required for maintenance of operating efficiency.

Other things being equal, the oil engine with the least number of vital working parts will most adequately meet the demand for reliable low-cost power, particularly so under American conditions of high labor and relatively low fuel costs.

It is conceded that a perfected oil engine of the two-stroke type admits of the simplest possible construction for marine propulsion. The four-stroke marine engine suffers from inherent difficulty in reversing the mechanically operated inlet and exhaust valves as driven from the half-speed cam-shaft drive. Furthermore, the long-stroke slow-speed engine of the four-stroke type does not compare favorably in weight, floor space or in first cost with the cargo-ship type of two-stroke engine.

With but a single power impulse per cylinder for every two revolutions, the heavy power parts of a four-stroke engine do not work to advantage during the idle inlet- and exhaust-stroke periods. Hence the two-stroke engine is enabled to show a decided weight reduction and consequent lowering in first cost. For example, a six-cylinder slow-speed two-stroke engine suitable for cargo-ship propulsion can readily be made to deliver approximately 1¾ times as much shaft power for the same weight and floor space as will a four-stroke oil engine of the same speed and bore. This advantage is of decided importance when large merchant ships are to be engined, since the usefulness of such a prime mover is determined in a large measure by the ultimate power capacity to which a compact six- or eight-cylinder unit can be built.

Another advantage of the two-stroke engine is that it requires no mechanically operated inlet and exhaust valves. The cylinders of such oil engines are best charged from the under side of the power piston, through inlet poorts overrun by the piston. If desired, the scavenging air supply may be supplemented by additional low-pressure pumps but this is not essential when liberally proportioned injection-air compressors are provided.

With this mode of charging a two-stroke cylinder, the timing events of the inlet and exhaust ports must be correctly proportioned and the shape of the piston deflector lug must be properly designed to produce effective scavenging of the power cylinder, otherwise the incoming fresh-air charge will blow out of the exhaust ports without displacing the burnt products of combustion. Deficiency in oxygen for combustion of the fuel oil has been responsible for the failure of a number of two-stroke engine designs.

The described mode of charging two-stroke power cylinders reduces the valve gear parts to a minimum and requires only one air starting valve and one fuel valve opening into each cylinder head. Since these valves run in unison with the piston movements, they may be eccentric-driven and reversed by a Stephenson link in the manner of a steam-engine gear. The elimination of the half-speed cam-shaft drive is a feature of the two-stroke engine that makes for a simple and compact reversing valve gear.

While the thermal efficiency of a well-designed two-stroke engine is not quite as high as that of a four-stroke engine, the difference is not large. Most of the loss of economy is chargeable to the increased pump work required to charge the power cylinder, but the relatively small gain of about 10 per cent in brake efficiency in favor of the four-stroke engine is not in itself sufficient to offset the other advantages which a perfected two-stroke engine affords.

A good two-stroke engine is somewhat more difficult to design than a four-stroke engine, partly because of the greater heat flow through the cylinder walls. For equal bore dimensions, the rate of heat flow in a two-stroke engine is approximately 1.6 times that in a four-stroke engine running at the same speed.

The limiting rotative speed at which an oil or gas engine may be safely run is largely determined by the temperature assumed by the cylinder-bore wall, and if this is not kept within prescribed limits, troubles from piston lubrication and cracking of cylinder parts will result.

The temperature head required to drive heat at a given rate of flow through the cylinder wall increases with the wall thickness. For equal shaft power the bore dimensions of a four-stroke oil engine are about 4/3 those required for a two-stroke engine. Allowing for the thicker four-stroke cylinder wall and assuming equal rotative speeds, the rate of heat flow in the case of the two-stroke engine should not exceed 5/4 that obtained in a four-stroke cylinder of equal power capacity.

In high-speed marine oil engines, which are usually worked up to their limiting rate of heat flow, the four-stroke cycle offers some advantage. On the other hand, the relatively slow speed demanded for cargo-ship engines is exceptionally favorable to the two-stroke type, since these engines operate under heat-flow conditions so moderate as to allow ample cooling of all vital parts even in the largest-sized cylinders. It is therefore readily possible to keep the bore-wall temperatures of such two-stroke engines well below the critical limits required for safe and reliable running. To further safeguard against fatigue and breakdown, it is advisable to provide for liner cylinders and such other constructive features common in high-powered oil-engine practice, so as to give the cylinder parts the requisite long life and complete immunity against cracking.

The greater frequency of impulse and the consequent more even turning effort of the two-stroke engine largely improve the speed control and reduce to a minimum the flywheel effect needed for a smooth-running marine engine.

Still another feature of the two-stroke cycle that gives promise for rapid future development, is its special adaptability to the hot-bulb type of engine.

Judging from the recent trend of marine oil-engine developments, it now appears that a combination of the constant-pressure Diesel cycle with the hot-bulb constant-volume cycle is likely to overcome the defects of both parent types. The resulting cycle is especially suited to meet American oil-engine requirements, since the lowering of the maximum Diesel working pressure to approximately that used in the automobile engine will increase the reliability of operation.

The constant-volume or explosive engine, when working with

[1] Gas Engine Expert, American-Whaley Engine Co., Boston, Mass., Mem. Am.Soc.M.E.

a compression pressure of about 250 lb. per sq. in., shows a thermal shaft efficiency but little inferior to that of the Diesel engine. By further reducing the compression to about 150 or 175 lb. per sq. in. the fuel economy of the explosive engine is but slightly sacrificed, while for a given size of crankshaft the weight and cost relations as taken upon the power-output basis show a considerable improvement as compared with the high-compression engine.

An engine operating with the combined type of cycle should be provided with an efficient timed spray valve for the fuel-oil injection, and in large engines this should preferably be of the air-injection type used for Diesel engines.

When working with such limited compression, self-ignition may best be obtained by holding a portion of the products of combustion from stroke to stroke within a water-jacketed vaporizer chamber, without, however, requiring the use of a hot plate. The trapped hot burnt gases may then be used to preheat the air that is pressed into the bulb chamber to a point where it is capable of promoting self-ignition of the injected fuel oil. This sets up a light explosion at constant volume, after which the remaining oil may be gradually fed into the power cylinder in the manner of a Diesel engine.

While the water-cooled bulb will not of itself start the engine from the cold, it does not require an external flame; instead it is only necessary to preheat the small amount of air enclosed within the vaporizer chamber, which may readily be done by means of an electric coil heater or spark plug. After the first few explosive charges are thus ignited, the required heat transfer takes place from stroke to stroke to make the engine self-igniting.

The jacketed vaporizer is especially applicable to oil engines of the single-acting type, the bulb chamber being preferably formed centrally in the cylinder head about the cylinder axis. The timed fuel valve can then be made to inject straight through the bulb chamber and directly against the hot piston head. This arrangement gives the nozzle considerable distance for proper spray formation before striking the piston top, after which the oil charge spreads out over the piston-head surface and intimately mixes with all the air throughout the combustion chamber.

Finally it is pointed out that this late development in true semi-Diesel engines is especially suited to the two-stroke-cycle engine. In the four-stroke engine considerable constructive difficulties are involved in placing the mechanically operated inlet and exhaust valves about the water-cooled vaporizer chamber. Furthermore, in a two-stroke engine the vaporizer chamber may be kept at a smaller size with respect to the piston displacement, due to the fact that the confined hot gases have less chance to cool off between power impulses.

These and other advantages previously cited would indicate that a two-stroke semi-Diesel engine along the lines discussed should in the near future find favor for the propulsion of merchant ships and be capable of fully establishing the inherent possibilities of a slow-speed oil engine for marine service.

W. D. Ennis[1] (written). The value of this paper would be increased if the author would add particulars regarding the motors used. The mean effective pressures range from 87 to 91 lb. per sq. in., values often surpassed by stationary Diesel engines. Apparently the cylinders are the ordinary 4-cycle single-acting form, but there seems to be no statement of the fact.

A chief argument in favor of the crude-oil motor appears from Table 2, where "repeat orders" in 1916 are quoted for lines which began with this construction in 1912. What has happened since 1916?

It is to be assumed that the eight factors listed in the second paragraph are not presented as a complete list. In fact, the author refers to others, admitting a shorter life for the crude-oil motor and referring to the absence of sufficient data on maintenance costs. He also discusses what is almost an overwhelming disadvantage for any but slow-speed cargo ships, the multiplicity of cylinders. The largest cylinder in Table 2 is below 30 in. bore and develops only 333 hp. The largest plant listed is 4000 hp.

[1] Acting Professor of Mechanical Engineering, Columbia University, New York. Mem. Am.Soc.M.E.

It is doubtful whether steam can ever be eliminated in naval practice. Requirements for heating, humidifying and evaporators do not tend to decrease. It is even proposed now to use steam heat for submarines. It is difficult for internal-combustion engines to displace steam where they cannot displace it completely.

Table 1 is obviously based on coal fuel for steam. If oil fuel is used, the ratio R directly following the table becomes about 2.0 instead of 7.4.

Forrest E. Cardullo[1] characterized the adoption of the Diesel and analogous cycles as a standard as an advance too far in the direction of theory. He said he knew of no reason why a satisfactory producer for gasifying oil could not be designed which would operate continuously at 90 per cent efficiency or even higher. He referred to the number of times a plant operating Diesel or semi-Diesel engines must be laid up in order to clean out the engines. The practical weight of experience, and of actual reliability and cheapness, he believed, was in favor of the oil-type gas-producer fuel. Lewis H. Nash concurred in the idea of adopting the principle of gasifying oil in some type of gas producer.

Henry B. Oatley,[2] referring to Table 1 in which Mr. Morton presented the comparative weights of power plants in steamships and motorships, said that in the comparative installations aboard the U. S. S. *Maumee* and *Tioga*, steam and motor-driven ships, respectively, the Diesel-engine plant weighed decidedly more than the steam plant. The difficulties of getting high pressure and the limitations of superheaters of which the author spoke while discussing the heat elements of temperature range for the various types of engines existed, according to Mr. Oatley, only in the present motor designs, but he saw no difficulty in the further development of the types which have been successfully operated at pressures as high as 500 or 700 lb. per sq. in. Thus, with higher pressures and with higher degrees of steam temperature the boiler plant, in point of weight and size, would become markedly smaller, and the contrast in point of space occupied aboard the ship for the steam plant as compared to the motor plant would decrease, possibly to the point of being on a par. Mr. Oatley further criticized the argument advanced for preferring the motorship over the steam-driven ship by reason of the depreciation of the hull because of the sulphur content of coal and the amount of coal space required in the steam-driven ship, on the ground that rapid progress had been made in the utilization of oil as fuel for steam-driven ships, and that this practice would in all likelihood continue to increase.

O. C. Berry,[3] commenting on Mr. Cardullo's suggestion of gasifying oil in some type of gas producer, mentioned that in experiments conducted at Purdue University for the purpose of finding the best means of introducing into the mixture the heat required to vaporize the liquid fuel, it had been concluded that two elements are required to get the mixture in a burnable condition. In the first place, the temperature of the mixture must be hot enough to maintain in the liquid fuel sufficient vaporizing pressure so that the fuel, once reduced to a vapor, will stay in a vaporized state and get into the cylinder as a vapor and not a liquid. The other was the time element. Because of the smallness of this time element, though the temperatures are hot enough to maintain the required temperatures, still the mixtures retain their wet condition when they arrive in the cylinder. For this reason, observed Professor Berry, the hot spot had come into automobile practice as one of the solutions for the vaporization of kerosene, and he expressed his belief that it could be applied to good advantage to the use of fuels heavier than kerosene. A properly designed hot spot, he said, would eliminate the difficulty found in gas producers, where the temperature is often so ho

[1] Engineer of Tests, Curtiss Aeroplane & Motor Corp'n., Buffalo, N. Y. Mem. Am.Soc.M.E.

[2] Chemical Engineer, Locomotive Superheater Co., New York, N. Y. Mem. Am.Soc.M.E.

[3] Professor of Mechanical Engineering, Purdue University, Lafayette, Ind.

that it is not possible to keep a high enough compression without getting preignition.

Mr. Cardullo said in reply that in mentioning the gas producer he had intended to convey the idea of the actual combustion of oil in a producer so as to form a clean, burnable mixture in the engine.

L. H. Johnson[1] spoke of his experience with the two-cycle semi-Deisel hot-balb, hot-surface engine and stated that after investigating the various theories advanced to explain this type of engine he had finally formulated the following conclusion as to its operation: That the oil must be injected into the engine in the form of a spray or a mist, and if low compression is to be used, it must be sprayed against a hot surface and vaporized; then this oil gas mixes with the air compressed in the chamber and explodes by the heat of compression or the heat stored in the combustion chamber. Tests, he said, had convinced him that it is necessary for successful operation of the engine to remove the deposit of carbon or residue of material that is left in the cylinder. In the experiments to which he referred no trouble had been found in maintaining the right temperature necessary for successful operation and the main problem had been the elimination of the deposits.

Discussions of Mr. Arnold's Paper on a Suggested Formula for Rating Kerosene Engines

Harry F. Smith[2] thought that it would be altogether out of place to attempt to create any arbitrary standard of cubic-inch displacement for the determination of the horsepower of the kerososene-oil engine. He said he knew of tests recently made on substantially identical kerosene-oil engines in which the b.hp. developed differed by 100 per cent, due to change in cylinder design. That meant that the thermal efficiency of one engine was 100 per cent better than the other. It seemed to him, therefore, that the manufacturer who was in a position to double the thermal efficiency of the kerosene oil engine ought to be entitled to whatever benefits might accrue thereby, and not be handicapped by the action of the Society or of state legislatures in rating his engine at a certain horsepower according to its size or the number of pounds of cast iron put into it.

Stafford Montgomery[3] inquired whether the rating of kerosene engine builders from 8000 to 20,000 cu. in. per b.hp. was limited to kerosene engines or whether it applied also to gasoline engines. This question was referred to the meeting by the chairman.

Fredrik Ottesen[4] protested against manufacturers of large gas engines having to adopt the formula set forth in Mr. Arnold's paper.

William T. Magruder remarked that in the Ohio State University School of Aeronautics they had formulated a statement which was fairly accurate, that instead of using 13,000 or 14,000, 10,000 cu. in. represented quite closely the horsepower of a Curtiss aeroplane engine up to 100 per cent capacity, and increased speed after that did not give correspondingly increased horsepower. He said that the horsepower of a steam tractor is unknown until tested for the reason that its overload capacity is not like that of a boiler, one or two or three hundred per cent, but from four to five hundred per cent; and that in tests perfomed at the laboratories of the university tractors nominally rated at 20 hp. gave over 100 hp. and kept it up; on the other hand, in actual tests of kerosene and gasoline tractors on blocks, either in field work or in comparative b.hp. tests, many of the tractors fail to operate at their rated horsepower and not even their own experts could always get from them what the nameplates indicated they should deliver. Such being the conditions in practice, it appeared to him that by the standardization of horsepower, misunderstandings arising from the erroneous interpretation of the discrepancy between rated and actual horsepower could be avoided. He further observed that the question was bound to be soon taken up by the various legislatures and, as Mr. Arnold said in his paper, the conditions at present existing in the gas tractor and the kerosene tractor would be duplicated in the automobile if the Society did not take prompt and effective steps to translate the idea of a horsepower so as to make it intelligible to the average man who knows nothing about machinery or about mechanics.

John Chucan[1] assented to the remarks made by Professor Magruder and asserted that he had actually used for several years the formula proposed by Mr. Arnold and had found it to be very conservative. The formula, he said, was intended only for tractors and not for stationary engines or any other engines.

Discussion of Professor Berry's Paper on Standards of Carburetor Performance

Forrest E. Cardullo remarked that the carburetor design was intimately connected with the structural details of the engine, with the form of the admission parts, and especially with the form of the manifold. The real problem of carburetor design, as he saw it, was to get the combination of a carburetor and inlet port in an engine which would give a uniformly suspended mixture of minute droplets in air at the instant the spark fires the charge. In order to get at this, Professor Berry recommended the application of certain standards to the testing of the carburetor in order to determine the uniformity of the mixture under operating conditions of the engine. But this would not lead, say, to the knowledge of the best kind of a combination carburetor, manifold and engine which would enable an automobile to climb a good stiff hill at ten or fifteen miles per hour, and at the same time give a speed of three miles per hour in a crowded traffic street and a speed of fifty miles per hour on a smooth, clear road.

Mr. Cardullo further observed that a rich mixture could be secured at the instant of acceleration more by properly designing the form of the manifold than by providing methods for increasing the mixture. Also that by reason of the separator action of the manifold it would be impossible to get a representative sample of the mixture entering the cylinder, and he believed the proper thing to do would be to analyze the exhaust of each cylinder for the proportion of carbon dioxide in order to determine whether each cylinder was getting its due proportion of gasoline in the mixture provided.

Thomas J. Litle, Jr.,[2] observed that in automobile practice many difficulties are encountered which do not occur in stationary engine work. With reference to the statement in the paper that the best performance is obtained with a temperature of 80 deg., he preferred to take the temperature of the mixture entering the block, after it passes through the carburetor intake manifold. He claimed that the temperature of the charge as it entered the block, after it passed through the carburetor and intake manifold, was the controlling factor in motor performance. He suggested as a future line of research work tapping into the intake passage just at the end of the supply pipe and analyzing a sample of the mixture taken at that point. To a question of Chairman Magruder inquiring how that sample of air and gasoline vapor was going to be obtained, Mr. Litle explained that he had succeeded in drawing it off by lifting the valve of a tall gasometer with a long water still.

In closing the discussion Professor Berry called attention to the fact that a temperature of 300 deg. on the air in the carburetor had been used in all of the tests reported in the paper. He had

WORK OF THE BOILER CODE COMMITTEE

FOR over two years, a sub-committee of the Boiler Code Committee, known as the Sub-Committee on Railway Locomotive Boilers, has been engaged in formulating a set of rules for the construction of railway locomotive boilers, to be known as Part I, Section III, of the A. S. M. E. Boiler Code. The necessity for such an addition to the Boiler Code arose from the fact that, while the boilers of locomotives operated on railways engaged in interstate service are covered by the construction and inspection rules of the Interstate Commerce Commission, there was found to be a vast mileage of industrial and short-line railroads in operation in the various states, which by virtue of their location, are not subject to the Interstate requirements.

As a result of calls for a Code to cover the construction of boilers of this class, the Sub-committee on Railway Locomotive Boilers was appointed in 1916, and great care was taken to select for the membership of this Sub-committee men particularly qualified for the work. The Sub-committee of the Boiler Code Committee on Railway Locomotive Boilers consists of the following members:

F. H. CLARK, *Chairman*
F. J. COLE
ALEX. C. HUMPHREYS
S. F. JETER
WM. F. KIESEL, JR.
H. H. VAUGHAN.

While the work of this Sub-Committee was interrupted somewhat during the period of the war, its investigations were completed in the earlier part of the year and a preliminary report was submitted to the Boiler Code Committee in April. The preliminary report was next printed and distributed at the Spring Meeting at Detroit in June where it was discussed and upon motion, the preliminary report of the Committee was accepted by the meeting. The report is here published for the information of the membership. Any one desiring to discuss the preliminary report is requested to address the Secretary of the Boiler Code Committee, 29 West Thirty-Ninth Street, New York, N. Y.

A. S. M. E. BOILER CODE

PART I—SECTION III

PRELIMINARY REPORT ON RULES FOR THE CONSTRUCTION OF BOILERS OF LOCOMOTIVES WHICH ARE NOT SUBJECT TO FEDERAL INSPECTION AND CONTROL[1]

NOTE—When this Section is incorporated in the Boiler Code, it will be desirable to change the word "STATIONARY," to "STEAM," at the top of front cover and of the title page and on page 3 of the Code. Also the sentence in italics on page 3 will be changed to read, as follows:

"*These rules do not apply to boilers which are subject to Federal inspection and control.*"

Also to insert, after bracket in line beginning Part I, the following:

"SECTION III—LOCOMOTIVE BOILERS"

SELECTION OF MATERIALS

L—1 (X—1) Specifications are given in the Rules for Power Boilers, Pars. 23 to 178, for the important materials used in the construction of boilers, and where so given, the materials herein mentioned shall conform thereto, except as noted in Par. L—18.

L—2 (X—2) Steel plates for any part of a boiler when exposed to the fire or products of combustion, and under pressure, *excepting front tube sheets*, shall be of firebox quality as designated in the Specifications for Boiler Plate Steel.

L—3 (3) Steel plates for any part of a boiler, where firebox quality is not specified, when under pressure, shall be of firebox or flange quality, as designated in the Specifications for Boiler Plate Steel.

L—4 (4) Braces, when welded, shall be of wrought iron of the quality designated in the Specifications for Refined Wrought Iron Bars.

L—5 (5) Manhole and handhole covers and other parts subjected to pressure, and braces and lugs when made of steel plate, shall be of firebox or flange quality, as designated in the Specifications for Boiler Plate Steel.

L—6 (6) Steel bars for braces and for other boiler parts, except as otherwise specified herein, shall be of the quality designated in the Specifications for Steel Bars.

L—7 (X—7) Staybolts shall be of iron of the quality designated in the Specifications for Staybolt Iron.

L—8 (8) Rivets shall be of steel or iron of the quality designated in the Specifications for Boiler Rivet Steel, or in the Specifications for Boiler Rivet Iron.

L—9 (X—12) Throttle and throttle pipe, dry pipe or dry pipe ring, tee head, superheater header and steam pipes to cylinders, may be of cast iron.

L—10 (13) Water-leg and door-frame rings shall be of wrought iron or steel, or cast steel of Class A or Class B grade, as designated in the Specifications for Steel Castings. The OG or other flanged construction may be used as a substitute in any case.

ULTIMATE STRENGTH OF MATERIAL USED IN COMPUTING JOINTS

L—11 (14) In determining the maximum allowable working pressure, the tensile strength used in the computations for steel plates shall be that stamped on the plates as herein provided, which is the minimum of the stipulated range, or 55,000 lb. per sq. in. for all steel plates, except for special grades having a lower tensile strength.

TABLE 1 MINIMUM THICKNESS OF BUTT STRAPS

Thickness of Shell Plates, Inches	Minimum Thickness of Butt Straps, Inches	Thickness of Shell Plates, Inches	Minimum Thickness of Butt Straps, Inches
1/4	1/4	17/32	7/16
9/32	1/4	9/16	7/16
5/16	1/4	5/8	1/2
11/32	1/4	3/4	1/2
3/8	5/16	7/8	5/8
13/32	5/16	1	11/16
7/16	3/8	1 1/8	3/4
15/32	3/8	1 1/4	7/8
1/2	7/16		

L—12 (15) The resistance to crushing of steel plate shall be taken at 95,000 lb. per sq. in. of cross-sectional area.

L—13 (16) In computing the ultimate strength of rivets in shear, the following values in pounds per square inch of the cross-sectional area of the rivet shank shall be used:

Iron rivets in single shear	38,00
Iron rivets in double shear	76,00
Steel rivets in single shear	44,00
Steel rivets in double shear	88,00

The cross-sectional area used in the computations shall be tha of the rivet shank after driving.

[1] Numbers in parentheses at the beginning of paragraphs indicate paragraphs in A.S.M.E. Boiler Code (Edition of 1918) to which these paragraphs correspond.
The letters X, Y and Z indicate as follows: X—Rules of present Boiler Code modified; Y—New rules; Z—Interstate Commerce Commission rules.
Presented at the Spring Meeting, Detroit, Mich., June 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Minimum Thickness of Plates and Tubes

L—14 (17) The minimum thickness of any boiler plate under pressure shall be $\frac{1}{4}$ in.

L—15 (18) The minimum thickness of shell plates, and dome plates after flanging, shall be as follows:

When the Inside Diameter of Shell is

36 in. or Under	Over 36 in. to 54 in.	Over 54 in. to 72 in.	Over 72 in.
$\frac{1}{4}$ in.	$\frac{5}{16}$ in.	$\frac{3}{8}$ in.	$\frac{1}{2}$ in

L—16 (19) The minimum thickness of butt straps for double strap joints shall be as given in Table 1. Intermediate values shall be determined by interpolation. For plate thicknesses exceeding $1\frac{1}{4}$ in., the thickness of the butt straps shall not be less than two-thirds of the thickness of the plate.

L—17 (X—20) The minimum thickness of tube sheets for locomotive boilers, shall be as follows:

When Diameter of Tube Sheet is

42 in. or Under	Over 42 in. to 54 in.	Over 54 in.
$\frac{3}{8}$ in.	$\frac{7}{16}$ in.	$\frac{1}{2}$ in.

L—18 (X—22) The minimum gage thickness of tubes or flues exposed to the products of combustion on the inside shall be as specified in Table 2 for the various pressures and outside diameters given.

The gage thickness in Table 2 is that measured by the B. W. gage with a permitted variation in thickness at any section not varying more than 10 per cent from that specified, except at the weld of lap-welded tubes where an additional thickness of 0.015 in. shall be allowed. In the case of superheater tubes which are expanded, the gage of the expanded end may be $1\frac{1}{2}$ gages lighter and the swaged end two gages heavier than the gage thickness.

TABLE 2 MINIMUM THICKNESS OF WALLS OF FIRE TUBES

Outside Diameter, In.	Maximum Allowable Working Pressure, Lb. per Sq. In.				
	160	180	200	225	250
$1\frac{1}{2}$	13	13	12	..	..
$1\frac{3}{4}$	13	12	12	.	..
2	12	12	12	11	11
$2\frac{1}{4}$	12	12	12	11	11
$2\frac{1}{2}$	12	12	11	11	11
3	12	11	11	11	10
$3\frac{1}{2}$	11	11	11	10	10
4	11	10	10	10	9
$4\frac{1}{2}$	10	10	10	9	9
5	10	9	9	9	8
$5\frac{1}{2}$	9	9	9	8	8
6	9	9	8	8	7

L—19 (Y) The minimum thickness of walls of brick arch tubes shall be determined by the following formula:

$$t = \frac{PD}{16{,}000} + \frac{1}{8} \text{ in.}$$

where P = allowable boiler pressure, lb. per sq. in.
t = thickness of walls, in.
D = outside diameter, in.

Construction and Maximum Allowable Working Pressure for Boilers of Locomotives

L—20 (179) The maximum allowable working pressure is that at which a boiler may be operated as determined by employing the factors of safety, stresses and dimensions designated in these rules.

No boiler shall be operated at a higher pressure than the maximum allowable working pressure, except when the safety valve or valves are blowing, at which time the maximum allowable working pressure shall not be exceeded by more than six per cent.

Wherever the term "Maximum Allowable Working Pressure" is used herein, it refers to gage pressure, or the pressure above the atmosphere, in pounds per square inch.

L—21 (X—180) The maximum allowable working pressure on the shell of a boiler shall be determined by the strength of the weakest course, computed from the thickness of the plate, the tensile strength stamped thereon, as provided for in Specifications for Boiler Plate Steel, the efficiency of the longitudinal joint, the inside diameter of the course, and the factor of safety.

$$\frac{TS \times t \times E}{R \times FS} = \text{maximum allowable working presure, lb. per sq. in.}$$

where

TS = ultimate tensile strength stamped on shell plates, as provided for in Specifications for Boiler Plate Steel, lb. per sq. in.
t = minimum thickness of shell plates in weakest course, in.
E = efficiency of longitudinal joint.
R = inside radius of the weakest course of the shell, in.
FS = factor of safety, or the ratio of the ultimate strength of the material to the allowable stress. For new constructions covered in Part III, FS in the above formula = 4.

Boiler Joints

L—22 (181) The efficiency of a joint is the ratio which the strength of the joint bears to the strength of the solid plate. In the case of a riveted joint this is determined by calculating the breaking strength of a unit section of the joint, considering each possible mode of failure separately, and dividing the lowest result by the breaking strength of the solid plate of a length equal to that of the section considered. (See Appendix, Pars. 410 to 416, Power Boilers, for detailed methods and examples.)

L—23 (X—182) The distance between the center lines of any two adjacent rows of rivets, or the "back pitch" measured at right angles to the direction of the joint, shall have the following minimum values:

a If $\frac{P}{D}$ is 4 or less, the minimum value shall be $1.75D$;

b If $\frac{P}{D}$ is over 4, the minimum value shall be:

$$1.75\,D + 0.1\ (P - 4\,D)$$

where

P = pitch of rivets in outer row where a rivet in the inner row comes midway between two rivets in the outer row, in.
P = pitch of rivets in the outer row less pitch of rivets in the inner row where two rivets in the inner row come between two rivets in the outer row, in. (It is here assumed that the joints are of the usual construction where the rivets are symmetrically spaced.)
D = diameter of the rivet holes, in.

L—24 (X—183) On longitudinal joints the distance from the centers of rivet holes to the edges of the plates, except rivet holes in the ends of butt straps, shall be not less than one and one-third times the diameter of the rivet holes.

L—25 (X—184) The strength of circumferential joints of boilers shall be at least 50 per cent of that required for the longitudinal joints of the same structure.

L—26 (187) The longitudinal joints of a shell which exceeds 36 in. in diameter, shall be of butt and double-strap construction.

This rule does not apply to the portion of a boiler shell which is stayed to the firebox or combustion chamber.

L—27 (188) The longitudinal joints of a shell which does not exceed 36 in. in diameter, may be of lap-riveted construction; but the maximum allowable working pressure shall not exceed 100 lb. per sq. in.

L—28 (X—190) With butt and double-strap construction longi-

tudinal joints of any length may be used, provided the tension test specimens are so cut from shell plates and butt-strap plates that their lengthwise direction is parallel with the circumferential seams of the boiler, and the tests meet the standards prescribed in the Specifications for Boiler Plate Steel.

L—29 (191) Butt straps and the ends of shell plates, forming the longitudinal joints shall be rolled or formed by pressure, not blows, to the proper curvature.

L—30 (X—194) The longitudinal joint of a dome shall be of butt and double-strap construction or made without a seam of one piece of steel pressed into shape, and its flange shall be double-riveted to the boiler shell, unless the dome be less than 24 in. in diameter, in which case the longitudinal joint may be of the lap type, and its flange may be single-riveted to the boiler shell provided the maximum allowable working pressure on such a dome does not exceed 160 lb. per sq. in., and is computed with a factor of safety not less than 8.

(Y) When boiler shells are cut to apply steam domes or manholes, the amount of metal in flange and liner, if used, must provide strength equivalent to that of the metal removed multiplied by the efficiency factor of the longitudinal seams. A height of vertical flange equal to three times the thickness of flange shall constitute flange reinforcement, using net area after rivet holes are deducted.

Braced and Stayed Surfaces

L—31 (X-199) The maximum allowable working pressure for various thicknesses of braced and stayed flat plates and those which by these Rules require staying as flat surfaces with braces or stays of uniform diameter symmetrically spaced, shall be calculated by the formula:

$$P = C \times \frac{T^2}{p}$$

where

P = maximum allowable working pressure, lb. per sq. in.

T = thickness of plate in sixteenths of an inch

p = maximum pitch measured between straight lines passing through the centers of the staybolts in the different rows, which lines may be horizontal, vertical or inclined, in.

C = 112 for stays screwed through plates not over $\frac{7}{16}$ in. thick with ends riveted over

C = 120 for stays screwed through plates over $\frac{7}{16}$ in. thick with ends riveted over

C = 135 for stays screwed through plates and fitted with single nuts outside of plate

C = 150 for stays with heads not less than 1.3 times the diameter of the stays, screwed through plates or made a taper fit and having the heads formed on the stays before installing them and not riveted over, said heads being made to have a true bearing on the plate.

If flat boiler plates not less than $^3/_8$ in. thick are strengthened with doubling plates securely riveted thereto and having a thickness of not less than $^2/_3$ T, then the value of T in the formula shall be three-quarters of the combined thickness of the boiler plate, and doubling plates, but not more than one and one-half times the thickness of the boiler plate, and the values of C given above may also be increased 15 per cent.

When two sheets are connected by stays and but one of these sheets requires staying, the value of C is governed by the thickness of the sheet requiring staying.

In curved sheets of a combustion chamber, half of which is a semicircle (radius R, in.) an increased pitch (p_i, in.) based on the following formula, may be used:

$$p_i = p\sqrt{\frac{PR}{PR - 250T}}$$

L—32 (X-200) The ends of screwed staybolts shall be riveted over or upset by equivalent process. The outside ends of solid staybolts 8 in. and less in length shall be drilled with a hole at least $\frac{3}{16}$ in. diameter to a depth extending at least $^1/_2$ in. beyond the inside of the plates, or hollow staybolts may be used. Solid staybolts over 8 in. long and flexible staybolts of either the jointed or ball and socket type need not be drilled.

Staybolts behind brickwork, frame braces, or grate bearers shall have holes at least $\frac{3}{16}$ in. diameter for entire length, which must be kept open at all times.

L—33 (201) When channel irons or other members are securely riveted to the boiler heads, the stress on such members shall not exceed 12,500 lb. per sq. in. In computing the stress the section modulus of the member shall be used without addition for the strength of the plate. This spacing of the rivets over the supported surface shall be in conformity with that specified for staybolts.

If the outstanding legs of the two members are fastened together so that they act as one member in resisting the bending action produced by the load on the rivets attaching the members to the head of the boiler, and provided that the spacing of those rivets attaching the members to the head is approximately uniform, the members may be computed as a single beam uniformly loaded and supported at the points where the through braces are attached.

L—34 (202) The ends of stays fitted with nuts shall not be exposed to the direct radiant heat of the fire.

L—35 (X-203) *a* The maximum spacing between centers of rivets or between the edges of tube holes and the centers of rivets attaching the crowfeet of braces to the braced surface, shall be determined by the formula in Par. L—31, using 135 for the value of C.

b The maximum distance between the edges of tube holes and the centers of other types of stays shall be determined by the formula in Par. L—31, using the value of C given for the thickness of plate and type of stay used.

c The maximum spacing between the inner surface of the shell and lines parallel to the surface of the shell passing through the centers of the rivets attaching the crowfeet of braces to the head shall be determined by the formula in Par. L—31, using 175 for the value of C.

d The maximum distance between the inner surface of the shell and the centers of braces of other types shall be determined by the formula in Par. L—31, using a value of C equal to 1.3 times that value of C, which applies to the thickness of plate and type of stay as therein specified.

e In applying these Rules and those in Par. L—31 to a head or plate having a manhole or reinforced opening, the spacing applies only to the plate around the opening and not across the opening.

L—36 (Y) *a* When the edge of a stayed plate is flat and is fastened by riveting, the distance from the center line of the rivets to a line through the centers of the nearest row of stays may be made to equal the pitch of the stays as given in Table 3 plus twice the thickness of the plate.

b When the edge of a flat stayed plate is flanged and riveted, the distance from the center of the outermost stays to the inside of the supporting flange should not exceed the pitch of the stays from the table plus the inside radius of the flange.

L—37 (X-204) Where values for screwed stays with ends riveted are required for conditions not given in Table 3, they may be computed from the formula in Par. L—31 and used, provided the pitch does not exceed $8^1/_2$ in.

L—38 (206) The distance between the edges of the staybolt holes may be substituted for p for staybolts adjacent to a furnace door or other boiler fitting, tube hole, handhole or other opening.

L—39 (X-208) The diameter of a screw stay shall be taken at the bottom of the thread, or at the body of the bolt between the threads—whichever is the lesser.

L—40 (X-209) The least cross-sectional area of a stay shall be taken in calculating the allowable stress, except when the stays are welded and have a larger cross-sectional area at the weld than at some other point, in which case the strength at the weld shall be computed as well as in the solid part and the lower value used.

L—41 (210) Holes for screw stays shall be drilled full size or punched not to exceed $\frac{1}{4}$ in. less than full diameter of the hole for plates over $\frac{5}{16}$ in. in thickness, and $\frac{1}{8}$ in. less than the full diameter of the hole for plates not exceeding $\frac{5}{16}$ in. in thickness,

TABLE 3 MAXIMUM ALLOWABLE PITCH, IN INCHES, OF SCREWED STAYS, ENDS RIVETED OVER

Pressure Lb. per Sq. In.	Thickness of Plate, In. — Maximum Pitch of Staybolts, In.						
	$\frac{5}{16}$	$\frac{3}{8}$	$\frac{7}{16}$	$\frac{1}{2}$	$\frac{9}{16}$	$\frac{5}{8}$	$\frac{11}{16}$
100	$5\frac{1}{4}$	$6\frac{3}{8}$	$7\frac{3}{8}$	...	...		
110	5	6	7	$8\frac{3}{8}$	...		
120	$4\frac{3}{4}$	$5\frac{3}{4}$	$6\frac{3}{4}$	8			
125	$4\frac{3}{4}$	$5\frac{5}{8}$	$6\frac{5}{8}$	$7\frac{3}{4}$			
130	$4\frac{5}{8}$	$5\frac{1}{2}$	$6\frac{1}{2}$	$7\frac{5}{8}$			
140	$4\frac{1}{2}$	$5\frac{3}{8}$	$6\frac{1}{4}$	$7\frac{3}{8}$	$8\frac{3}{8}$		
150	$4\frac{1}{4}$	$5\frac{1}{8}$	6	$7\frac{1}{8}$	8		
160	$4\frac{1}{8}$	5	$5\frac{7}{8}$	$6\frac{7}{8}$	$7\frac{3}{4}$		
170	$4\frac{1}{16}$	$4\frac{7}{8}$	$5\frac{5}{8}$	$6\frac{3}{4}$	$7\frac{1}{2}$	$8\frac{3}{8}$	
180	$3\frac{15}{16}$	$4\frac{3}{4}$	$5\frac{1}{2}$	$6\frac{1}{2}$	$7\frac{3}{8}$	$8\frac{1}{8}$	
190	$3\frac{13}{16}$	$4\frac{5}{8}$	$5\frac{3}{8}$	$6\frac{3}{8}$	$7\frac{1}{8}$	$7\frac{7}{8}$	
200	$3\frac{11}{16}$	$4\frac{1}{2}$	$5\frac{1}{4}$	$6\frac{1}{8}$	7	$7\frac{3}{4}$	$8\frac{1}{2}$
225	$3\frac{1}{2}$	$4\frac{1}{4}$	$4\frac{7}{8}$	$5\frac{7}{8}$	$6\frac{1}{2}$	$7\frac{1}{4}$	8
250	...	4	$4\frac{5}{8}$	$5\frac{1}{2}$	$6\frac{1}{4}$	$6\frac{7}{8}$	$7\frac{5}{8}$
300	...	...	$4\frac{1}{4}$	5	$5\frac{5}{8}$	$6\frac{1}{4}$	7

and then drilled or reamed to the full diameter. The holes shall be tapped fair and true, with a full thread.

L—42 (211) The ends of steel stays upset for threading shall be thoroughly annealed.

L—43 (X—212) *a* The maximum allowable working pressure for any curved stayed surface subject to internal pressure shall be obtained by the two following methods, and the minimum value obtained shall be used:

First, the maximum allowable working pressure shall be computed without allowing for the holding power of the stays, due allowance being made for the weakening effect of the holes for the stays. To this pressure there shall be added the pressure secured by the formula for braced and stayed surfaces given in Par. L—31, using 70 for the value of C.

Second, the maximum allowable working pressure shall be computed without allowing for the holding power of the stays, due allowance being made for the weakening effect of the holes for the stays. To this pressure there shall be added the pressure corresponding to the strength of the stays for the stresses given in Table 4, each stay being assumed to resist the steam pressure acting on the full area of the external surface supported by the stay.

TABLE 4 MAXIMUM ALLOWABLE STRESSES FOR STAYS AND STAYBOLTS

Description of Stays	Stresses, Lb. Per Sq. In. — For lengths between supports not exceeding 120 diameters	For lengths between supports exceeding 120 diameters
a Unwelded or flexible stays less than twenty diameters long, screwed through plates with ends riveted over................	7500	....
b Hollow steel stays less than 20 diameters long, screwed through plates with ends riveted over..	8000	....
c Unwelded stays and unwelded portions of welded stays, except as specified in line *a* and line *b*...	9500	8500
d Welded portions of stays..........	6000	6000

b The maximum allowable working pressure for a stayed wrapper sheet of a locomotive-type boiler shall be determined by the two methods given above and by the method which follows, and the minimum value obtained shall be used:

$$P = \frac{13{,}500t \times E}{R - s\Sigma \sin \alpha}$$

in which

α = angle any crown stay makes with vertical axis of boiler

$\Sigma \sin \alpha$ = summated value of $\sin \alpha$ for all crown stays considered in one transverse plane and on one side of vertical axis of boiler

s = transverse spacing of crown stays in crown sheet, in.

E = minimum efficiency of wrapper sheet through joints or stay holes

t = thickness of wrapper sheet, in.

R = radius of wrapper sheet, in.

P = working pressure of boiler, lb. per sq. in.

13,500 = allowable stress, lb. per sq. in.

L—44 (X—213) A segment of a head shall be stayed by through, diagonal, crowfoot or gusset stays.

L—45 (X—214) The area of a segment of a head to be stayed shall be the area enclosed by lines drawn 2 in. from the tubes and at a distance d from the shell as shown in Figs. 15 and 16, Part I, Section I. The value of d used may be the larger of the following values:

(1) d = the outer radius of the flange, not exceeding 8 times the thickness of the head

(2) $$d = \frac{5 \times T}{\sqrt{P}}$$

where

d = unstayed distance from shell in inches

T = thickness of head in sixteenths of an inch

P = maximum allowable working pressure in lb. per sq. in.

(Y) The feet for braces to back head and front tube sheet should be distributed so as not to concentrate the stress on any one section; preferably a proportion of the braces should be attached to the second course from the back head or front tube sheet.

(Y) No supporting value shall be assigned to the stiffness of inside liner plates on flat surfaces, except as provided in L—31.

L—46 (X—221) In calculating stresses for diagonal stays in Pars. L—47-48 the angularity of the stays must be taken into account.

L—47 (X—223) All rivet and pin holes shall conform to the requirements in Par. L—54 and the pins shall be made a neat fit. To determine the sizes that shall be used, proceed as follows:

1 Determine the "required cross-sectional area of the brace" by first computing the total load to be carried by the brace, and dividing the total load by the values of stresses given in Table 4.

2 Design the body of the brace so that the cross-sectional area shall be at least equal to the "required cross-sectional area of the brace."

3 Make the area of pins to resist double shear at least three-quarters of the "required cross-sectional area of the brace."

4 Make the combined cross-section of the eye at the side of the pin (in crowfoot braces) at least 25 per cent greater than the "required cross-sectional area of the brace."

5 Make the cross-sectional areas through the blades of diagonal braces where attached to the shell of the boiler at least equal to the required rivet section; that is, at least equal to one and one-quarter times the "required cross-sectional area of the brace."

6 Design each branch of a crowfoot to carry two-thirds the total load on the brace.

7 Make the net sectional areas through the sides of the crowfoot, tee irons, or similar fastenings at the rivet holes at least equal to the required rivet section; that is, at least equal to one and one-quarter times the "required cross-sectional area of the brace."

8 Make the combined cross-sectional area of the rivets at each end of the brace at least one and one-quarter times the "required cross-sectional area of the brace."

L—48 (X—224) Gusset stays when constructed of triangular

web plates secured to single or double angle bars along the two sides at right angles shall have a cross-sectional area (in a plane at right angles to the longest side and passing through the intersection of the two shortest sides) not less than 10 per cent greater than would be required for a diagonal stay to support the same surface, assuming the diagonal stay is at the same angle as the longest side of the gusset plate.

L—49 (X—230) Crown bars and girder stays for tops of combustion chambers and back connections, or wherever used, shall be proportioned to conform to the following formula:

$$\text{Maximum allowable working pressure} = \frac{C \times d^2 \times t}{(W - P) \times D \times W}$$

where

W = extreme distance between supports, in.
P = pitch of supporting bolts, in.
D = distance between girders from center to center, in.
d = depth of girder, in.
t = thickness of girder, in.
C = 7000 when the girder is fitted with one supporting bolt
C = 10,000 when the girder is fitted with two or three supporting bolts
C = 11,000 when the girder is fitted with four or five supporting bolts
C = 11,500 when the girder is fitted with six or seven supporting bolts
C = 12,000 when the girder is fitted with eight or more supporting bolts

Example: Given W = 34 in., P = 7.5 in., D = 7.75 in., d = 7.5 in., t = 2 in.; three stays per girder, C = 10,000; then substituting in formula:

Maximum allowable working pressure =

$$\frac{10{,}000 \times 7.5 \times 7.5 \times 2}{(34 - 7.5) \times 7.75 \times 34} = 161.1 \text{ lb. per sq. in.}$$

(Y) In boilers with crown bars supported on firebox side sheets, and sling stays, the sling stays shall be considered as carrying the entire load.

L—50 (248) *Tubes.* Tube holes shall be drilled full size from the solid plate, or they may be punched at least $\frac{1}{2}$ in. smaller in diameter than full size, and then drilled, reamed or finished full size with a rotating cutter.

L—51 (249) The sharp edges of tube holes shall be taken off on both sides of the plate with a file or other tool.

L—52 (X—250) The ends of the tubes shall be substantially rolled and beaded, or rolled and welded, at the firebox or combustion-chamber end, and rolled at the smokebox end; 10 per cent of the flues at the smokebox shall be beaded.

Riveting

L—53 (253) All rivet holes and staybolt holes and holes in braces and lugs shall be drilled full size or they may be punched not to exceed $\frac{1}{4}$ in. less than full diameter for material over $\frac{5}{16}$ in. in thickness, and $\frac{1}{8}$ in. less than full diameter for material not exceeding $\frac{5}{16}$ in. in thickness, and then drilled or reamed to full diameter. Plates, butt straps, braces, heads and lugs shall be firmly bolted in position by tack bolts for drilling or reaming all rivet holes in boiler plates, except those used for the tack bolts.

L—54 (254) After drilling or reaming rivet holes the plates and butt straps shall be separated, the burrs and chips removed, the plates and butt straps reassembled metal to metal with barrel pins fitting the holes, and with tack bolts.

L—55 (X—255) Rivets shall be of sufficient length to completely fill the rivet holes and form heads at least equal to those shown in Fig. 20, Part I, Section 1.

L—56 (256) Rivets shall be machine-driven wherever possible, with sufficient pressure to fill the rivet holes, and shall be allowed to cool and shrink under pressure. Barrel pins fitting the holes and tack bolts to hold the plates firmly together shall be used. A rivet shall be driven each side of each tack bolt before removing the tack bolt.

L—57 (257) The calking edges of plates, butt straps and heads shall be beveled to an angle not less than 70 deg. to the plane of the plate, and as near thereto as practicable. Every portion of the sheared surfaces of the calking edges of plates, butt straps and heads shall be planed, milled or chipped to a depth of not less than $\frac{1}{8}$ in. Calking shall be done with a round-nosed tool.

L—58 (X—265) A locomotive boiler shall have washout handholes or screw plugs, as follows: One at each corner of firebox just above mud ring; one in back head over fire door; one or more on each side of roof sheet above the level of crown sheet, which shall be staggered on opposite sides; one or more in barrel of boiler; and one or more in back head above crown sheet.

(Y) Screw plugs must have at least four full threads in the sheet, including reinforcement, if such is used.

L—59 (Y—268) All holes for injector checks, whistle, and safety valves when screwed into boiler, and all holes in boiler barrel, firebox, roof sheet, and all unstayed surfaces when diameter of the hole is over $3\frac{1}{4}$ in. and exceeds $4\frac{1}{2}$ times the thickness of the plate, must be reinforced with a liner or flange riveted to the boiler.

The thickness of the liner or flange must be at least 75 per cent of the thickness of the plate. The rivets must have a shearing strength of at least 52 per cent of the tensile strength of the metal removed.

Safety Valves

L—60 (Z—269) Every locomotive boiler shall be equipped with at least two safety valves, the capacity of which shall be sufficient to prevent, under any conditions of service, an accumulation of pressure more than 6 per cent above the specified boiler pressure.

L—61 (Z—271) Safety valves shall be set to pop at pressures not exceeding 6 b. above the working steam pressure. When setting safety valves, two steam gages shall be used, one of which must be so located that it will be in full view of the person engaged in setting such valves; and if the pressure indicated by the gages varies more than 3 lb., they shall be removed from the boiler, tested and corrected before the safety valves are set. Gages shall in all cases be tested immediately before the safety valves are set or any change made in the setting. When setting safety valves, the water level in the boiler shall not be above the highest gage cock.

L—62 (X—272) Safety valves may have the seat and bearing surface of the disk inclined at any angle between 45 deg. and 90 deg. to the center line of the spindle. The valves shall be rated at a pressure 3 per cent in excess of that at which the valve is set to blow.

All safety valves shall be so constructed that no detrimental shocks are produced through the operation of the valve.

L—63 (273) Each safety valve shall be plainly marked by the manufacturer. The markings may be stamped on the body, cast on the body, or stamped or cast on a plate or plates permanently secured to the body, and shall contain the following:

a The name or identifying trademark of the manufacturer
b The nominal diameter
c The steam pressure at which it is set to blow
d Blow down, or difference between the opening and closing pressures
e The weight of steam discharged in pounds per hour at a pressure 3 per cent higher than that for which the valve is set to blow
f A.S.M.E. Std.

L—64 (X—275) Safety-valve capacity may be checked in the following manner; and, if found sufficient, additional capacity need not be provided:

> By making an accumulation test with fire in good bright condition, and all steam exits closed, and fire forced under these conditions, the safety valves should relieve boiler and not allow an excess pressure of more than 6 per cent above the working pressure.

L—65 (X—278) Each safety valve shall have full-sized direct connection to the boiler.

L—66 (X-279) If a muffler is used on a safety valve it shall have sufficient outlet area to prevent back pressure from interfering with the proper operation and discharge capacity of the valve. The muffler plates or other devices shall be so constructed as to avoid any possibility of restriction of the steam passages due to deposit.

L—67 (280) When a boiler is fitted with two or more safety valves on one connection, this connection to the boiler shall have a cross-sectional area not less than the combined area of all of the safety valves with which it connects.

L—68 (X-283) The seats and disks of safety valves shall be of non-ferrous material.

L—69 (284) Springs used in safety valves shall not show a permanent set exceeding $\frac{1}{16}$ in. ten minutes after being released from a cold compression test closing the spring solid. The spring shall be so constructed that the valve can lift from its seat at least one-tenth the diameter of the seat before the coils are closed or before there is other interference.

L—70 (285) The spring in a safety valve shall not be used for any pressure more than 10 per cent above or below that for which it was designed.

L—71 (287) When the valve body is marked with the letters A.S.M.E. Std. as required by Par. L—64, this shall be a guarantee by the manufacturer that the valve conforms to the details of construction herein specified.

L—72 (X-290) Every boiler shall have proper outlet connections for the required safety valve or valves, independent of any other steam outlet connection or of any internal pipe in the steam space of the boiler, the area of opening to be at least equal to the aggregate nominal area of all of the safety valves to be attached thereto.

L—73 (X-291) Each boiler should have at least one water glass and lamp and two gage cocks for boilers 36 in. in diameter and under, and three gage cocks for boilers over 36 in. in diameter.

(Y) The lowest gage cock and the lowest reading of water glass shall not be less than 2 in. above the highest point of crown sheet on boilers 36 in. in diameter and under, and 3 in. for boilers over 36 in. in diameter. These are minimum dimensions, and on large locomotives, and those operating on steep grades, the height should be increased if necessary to compensate for change of water level on descending grades.

L—74 (X-292) No water-glass connection shall be fitted with an automatic shut-off valve.

L—75 (Z-296) Every boiler shall have at least one steam gage which will correctly indicate the working pressure. Care must be taken to locate the gage so that it will be kept reasonably cool, and can be conveniently read by the engineman.

Every gage shall have a siphon of ample capacity to prevent steam entering the gage. The pipe connection shall enter the boiler direct, and shall be maintained steam-tight between boiler and gage. The siphon shall be of brass, copper or bronze composition.

L—76 (297) The dial of the steam gage shall be graduated to not less than $1\frac{1}{2}$ times the maximum allowable working pressure on the boiler.

L—77 (298) Each boiler shall be provided with a valved connection not less than $\frac{1}{4}$-in. pipe size for attaching a test gage when the boiler is in service, so that the accuracy of the boiler steam gage can be ascertained.

Fittings and Appliances

L—78 (X-311) Locomotive boilers are to be equipped with at least one blow-off cock located at the lowest water space practicable, directly connected to the boiler, either with screw connections or flanged.

L—79 (X-315) Each boiler shall be equipped with two injectors, or two pumps, or one injector and one pump, with separate delivery pipes connected to the injector checks. The water shall be delivered to the boiler at a point nearer the front than the back flue sheet.

Hydrostatic Tests

L—80 (X-329) After a boiler has been completed, it shall be subjected to a hydrostatic test of 25 per cent above the maximum allowable working pressure. The pressure shall be under proper control so that in no case shall the required test pressure be exceeded by more than 6 per cent.

L—81 (330) During a hydrostatic test, the safety valve or valves shall be removed, or each valve disk shall be held to its seat by means of a testing clamp, and not by screwing down the compression screw upon the spring.

L—82 (X-331) In laying out shell plates, furnace sheets and heads in the boiler shop, care shall be taken to leave at least one of the stamps, specified in Par. 36 of Part I, Section I, so located as to be plainly visible when the boiler is completed. Butt straps shall have at least a portion of such stamps visible, sufficient for identification when the boiler is completed.

L—83 (X-332) Each boiler shall conform in every detail to these Rules, and shall be distinctly stamped with the symbol as shown in Fig. 23, Part I, Section I, denoting that the boiler was constructed in accordance therewith.

After obtaining the stamp to be used when boilers are to be constructed to conform with the A.S.M.E. Boiler Code, a state inspector, municipal inspector, or an inspector employed regularly by an insurance company which is authorized to do a boiler insurance business in the state in which the boiler is built and in the state in which it is to be used, if known, is to be notified that an inspection is to be made and he shall inspect such boilers during construction and after completion. At least two inspections shall be made, one before reaming rivet holes and one at the hydrostatic test. In stamping the boiler after completion, if built in compliance with the Code, the builder shall stamp the boiler in the presence of the inspector, after the hydrostatic test, with the A.S.M.E. Code stamp, the builder's name and the serial number of the manufacturer. A data sheet shall be filled out and signed by the manufacturer and the inspector. This data sheet, together

Official Symbol for Stamp to Denote The American Society of Mechanical Engineers Uniform Standard

with the stamp on the boiler, shall denote that it was constructed in accordance with the A.S.M.E. Boiler Code.

Each boiler shall be stamped adjacent to the symbol as shown in Fig. 24, Part I, Section I, with the following items, with intervals of about one-half inch between the lines:

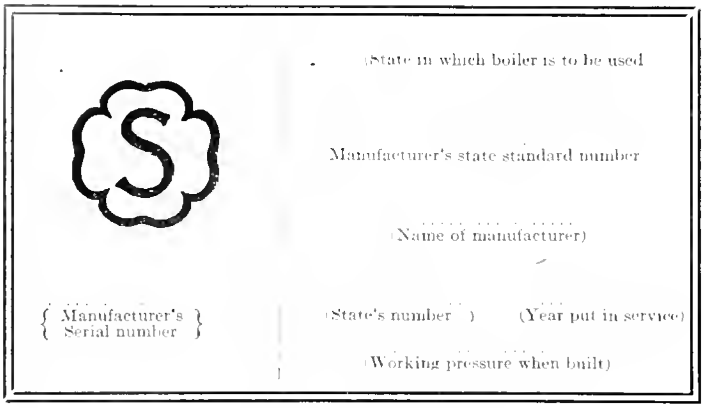
1. Manufacturer's serial number
2. State in which boiler is to be used
3. Manufacturer's State standard number
4. Name of manufacturer
5. State's number
6. Year put in service
7. Working pressure when built.

Items 1, 2, 3, 4 and 7 are to be stamped at the shop where built.

Items 5 and 6 are to be stamped by the proper authority at point of installation.

L-84 (X-333) The stamps shall be located on the boiler head in the cab and should not be covered by lagging and jacketing if the boiler head is lagged.

L-85 (X-334) Each boiler shall be equipped with a metal badge plate, showing the maximum allowable working pressure, which shall be attached to boiler head in the cab. If the boiler head is lagged, the lagging and jacketing shall be cut away a sufficient amount to leave the plate visible.



Form of Stamping

Use of the Boiler Code in Universities

Recognition of the value of the A. S. M. E. Boiler Code as an agency for standardization in this important branch of the industrial field is indicated by its growing use in technical schools and universities as a reference work or textbook. There has been found to be a growing number of engineering departments in the universities of this country which are either utilizing the Code as a reference work, a textbook or as a manual upon which to base their instruction in boiler design.

A. M. Greene, Jr., professor of mechanical engineering, Rensselaer Polytechnic Institute, Troy, N. Y., and member of the Boiler Code Committee, recently canvassed the engineering departments of the various universities and technical schools in order to learn the present status of the Code as an instruction work and the result is of more than usual interest. For the convenience of those having occasion to investigate this matter, the following summary of reports from engineering departments is given.

The following universities use the Boiler Code as a textbook: Massachusetts Institute of Technology, Sheffield Scientific School, Yale University, Armour Institute of Technology (Chicago), Case School of Applied Science (Cleveland), University of Vermont, University of Cincinnati, Johns Hopkins University (Baltimore), University of Michigan, University of Minnesota, and Rensselaer Polytechnic Institute. Rutgers College and University of Texas start with the coming year to make use of the Code as a textbook. The Boiler Code is used as a reference book at the following universities: Vanderbilt University (Tennessee), New Mexico College of Agriculture and Mechanic Arts, Tulane University of Louisiana, University of Colorado, University of Washington, University of Maine, University of Wyoming, Virginia Polytechnic Institute, and Washington University (St. Louis).

CORRESPONDENCE

Contributions to the Correspondence Departments of Mechanical Engineering by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

Contributions on Society Policy

Mr. Calvin W. Rice, *Secretary:*

In our efforts to place the organization of The American Society of Mechanical Engineers well abreast of the agencies making for an ever-greater America, we should be unmindful of the lessons of the past if we fail to give special attention to the development of the mechanisms making for free discussion and free speech. Hence it is that the policy which is to control the conduct of the Correspondence Department in Mechanical Engineering is by no means without its importance in the whole scheme of A. S. M. E. activities. Should it not be so conducted as to afford one of the principal outlets for comment on, and constructive criticism of, the Society's management and affairs? This is not now its function. In the six issues, January to June of this year, there have been published twelve (12) communications occupying about as many pages and every one of these letters is devoted exclusively to some technical phase of engineering. During the past six months there has not been published a line of "suggestions on Society affairs," which is the kind of contributions which are "particularly welcomed" according to the announcement which stands at the head of the section. This fact is especially significant because during this six months the affairs of the Society have been under special investigation at the hands of the Committee on Aims and Organization.

The late Dr. S. Weir Mitchell, shortly after I was put in charge of Philadelphia's public works, made the suggestion that we should adopt the policy of not only welcoming complaints and constructive criticism but of actively organizing to secure them. He rightly considered such an attitude as fundamental to the building up of our work. Following his advice in the next few months we handled over 100,000 complaints. But with all outlets for criticism thrown wide open and every effort being made by our organization to remedy the causes of criticism, it was not long before the volume of complaints began to recede. The character of the criticisms also became more constructive and we began to receive letters of commendation in increasing number. I am confident that no really great program making for progress can be executed in any field without constantly affording every one at interest a broad opportunity for comment and criticism.

"Formulated rules for the acceptance or rejection" of communications of this character should be very simple. Especially in the beginning I would publish everything offered unless there is an overpowering reason against doing so. At the present time the feeling is quite prevalent that the doors to criticism are not wide open. Until confidence in this matter is fully established the editor is not likely to be overwhelmed with suggestions. As our membership constitutes a carefully selected group the expectation is decidedly against the necessity for the rejection of contributions for cause. In order to fully establish confidence an appeal should be provided where a communication is rejected for cause.

The democratization of the A. S. M. E. will be impossible except as this and other channels for critical comment are thrown wide open. We need to remind ourselves constantly that the cure for democracy is more of it.

Morris Llewellyn Cooke.

Philadelphia, Pa.

To Mr. Cooke's letter the Secretary has replied as follows:

It is recognized that Mechanical Engineering can be improved and developed in various ways and the problem of how best to do that is now being given careful consideration by men with publishing experience and having a thorough acquaintance with the Society's organization and activities.

On account of lack of space and for other reasons which it is not necessary or desirable to specify for the moment, it has been impossible to do immediately all the things that were perceived to be desirable, and a number of them have had to be deferred.

One of these is the further development of the correspondence department in Mechanical Engineering which you now advocate. No communications of the character you so wisely sug-

gest have been received, except possibly Mr. Crawford's—with which I assume you are familiar, and my reply to that was in effect that we were already doing what he proposed, but nevertheless, if he would condense his letter we would be glad to publish it. He never came back.

It is hoped that the crowded condition of MECHANICAL ENGINEERING will soon be remedied, as it is generally agreed that it would be very desirable to afford, by means of our journal, a channel of communication between members of the Society; not only upon technical matters, but upon Society affairs as well.

CALVIN W. RICE, *Secretary.*

Fire Engines and the Essentials of Fire Fighting

To the Editor:

Mr. Fox's paper on Fire Engines and the Essentials of Fire Fighting, presented at the Spring Meeting, covers the general subject in a most complete manner and no particular phase of the many items involved has been given undue prominence to the exclusion of others. However, in order to refresh the minds of those who have dealt with some of the problems in times past and to put on guard those who may be called upon to apply some of the principles without having time to give them proper consideration, it may be desirable to treat certain parts of the subject more in detail.

Although the principles of design of the centrifugal pump and of the gasoline engine are well known by the designers of each class of equipment, yet the observations of the writer during the past ten years show that much trouble is encountered when the centrifugal-pump manufacturer purchases a gasoline engine and attempts to drive his pump with it, or when the manufacturer of a gasoline engine attempts to drive a centrifugal pump with his engine.

The pump manufacturer has tested his pump and determined its most economic speed, capacity and pressure, while the gasoline-engine manufacturer has determined the horsepower delivered at different speeds. In many cases sufficient study is not given to the performance curves of the two pieces of equipment before the capacity and size of each which are to be selected to form the combined motor-driven pump are determined.

In order to have the equipment successful it is fundamentally necessary that the power developed by the gasoline engine at any speed shall exceed that required to operate the centrifugal pump at the same speed. To the casual reader this statement may appear entirely superfluous, yet the failure to meet this axiomatic requirement has cost many manufacturers much time, money and trouble.

The writer is in absolute accord with the statement that the efficacy of fire streams up to $2\frac{1}{4}$ in. in diameter cannot be materially improved by increasing the nozzle pressure beyond 100 lb. per sq. in. Observations made on a $1\frac{1}{2}$-in. stream by experienced observers showed that the increase in the effective vertical reach when the nozzle pressure was increased beyond 100 lb., was not over 15 ft. up to 150 lb. pressure and that when the nozzle pressure was increased beyond 150 lb. the effective vertical reach decreased. This decrease was evidently due to the increased resistance which the air offered to the surface of the water jet. It is thus evident that a pressure of from 80 to 100 lb. at the nozzle is required to develop efficient streams from deluge sets, turret nozzles, deck guns, ladder pipes and water towers; for hand lines, even when operated by trained men, 60 to 80 lb. is sufficient. There are a few cases, however, when pressures in excess of 100 lb. may be of some advantage on 2-in. and $2\frac{1}{4}$-in. tips. For instance, in overhauling lumber when stacked, overturning walls or breaking through obstructions when the nozzle can be brought up close, and horizontal or vertical reach are not desired, pressures as high as 200 lb. at the nozzle enable the operator to take advantage of the added momentum of the stream and accomplish more efficient work.

In passing, it may not be out of place to remark that one of the best methods of placing a fire stream in favorable position for observations is to carry them out at night with the stream directed between a bank of electric lights and the observer.

The capacity of a pumper or steamer should always be stated in gallons per minute against the observed net pressure, the latter to be the actual difference in the pressures observed on the suction and discharge sides of the pump. As an example two cases will be cited: (1) An engine is taking suction from a reservoir 5 ft. below the suction inlet and the friction loss through the suction hose when delivering 750 gal. per min. is $6\frac{1}{2}$ ft., making the total lift 11.5 ft. or 5 lb.; the observed discharge pressure is 115 lb., therefore the net head pumped against by the engine is 120 lb. (2) An engine is taking suction from a hydrant fed by a street main carrying a pressure of 55 lb. when the engine is delivering 750 gal.; the friction loss through the hydrant and branch is 3 lb. and through the suction hose 2 lb., making the total friction loss 5 lb., thus delivering a pressure of 50 lb. on the suction side of the pump; the observed discharge pressure is 170 lb., therefore the net pressure pumped against by the engine is 120 lb.

Many engineers of steamers have maintained that their engines worked better at draft than when suction was furnished under pressure from a hydrant. It is the opinion of the writer that this is an erroneous notion and he has never seen it substantiated in practice. At any rate it is an established fact that the pressure furnished on the suction side of the pump increases the capacity of a pumper when delivering at pressures above that pressure at which it is rated.

If a pumper is rated at 750 gal. at 120 lb. net pressure and water is delivered to the suction side of the pump at 0 lb. pressure, then it will discharge somewhat more than one-half this quantity at 200 lb. pressure and a little more than one-third the quantity at 250 lb. pressure. Now if water is delivered to the suction side of the pump under 80 lb. pressure the discharge pressure will be 200 lb. and the capacity will remain at 750 gal., and if the water is delivered to the suction under 130 lb. pressure the pump will continue to discharge 750 gal. per min. with a discharge pressure of 250 lb.

It is thus evident that the pressure in the water mains should be taken advantage of in all cases. This is particularly important in large fires where high pressures are required to develop the more powerful streams and to overcome the friction losses in long lines of fire hose which must be laid from the engines located farthest from the fire. Where good hydrant pressures are available, say from 40 to 60 lb., the more nearly can the rated capacities of the engines be maintained when required to work against discharge pressures greater than 120 lb.

The one and main object of the pumper or steamer is to deliver water at the nozzle at a pressure suitable to develop an efficient fire stream. Now it has been shown that any increase in discharge pressure reduced the delivery of the apparatus, therefore every means should be adopted which will relieve the necessity of raising the discharge pressure. Increasing the carrying capacity of the hose lines from the engine to the nozzle will cut down the friction loss which in turn will cut down the pressure at the engine which is required to deliver the water at the nozzle under suitable pressure.

The use of 3-in. hose will accomplish this result in the most economical manner and practically the same results can be accomplished by siamesing $2\frac{1}{2}$-in. hose lines. For a given quantity of water flowing the friction loss through a 3-in. hose line is about one-third that through a $2\frac{1}{2}$-in. line of equal length. Two $2\frac{1}{2}$-in. lines siamesed offer about one-fourth the frictional resistance of a single $2\frac{1}{2}$-in. line. It therefore is advisable to lay 3-in. hose lines from pumpers to the entrance of buildings and to ladder pipes, turret nozzles, deluge sets and water towers in order to enable the pumper to deliver larger quantities of water.

The successful fighting of a fire depends much upon the development of powerful hose streams and these in turn depend upon the efficient operation of the pumpers or steamers. An untrained and unexperienced engineer may so operate an engine that is in first-class condition that it will not give as good service as a much poorer engine is well-trained hands. So much depends upon the operation of pumpers and steamers that it is of prime

importance that the crews be trained in the operation of their machines at capacity at frequent intervals, say, once a month.

Clarence Goldsmith.

New York, N. Y.

Comment on the Still Engine

To the Editor:

Roughly, an internal-combustion engine converts a third of its heat supply into power and throws away another third in the jacket discharge and a final third in the exhaust. The Still engine represents an attempt to reclaim the wasted two-thirds by means of a steam plant. The steam-plant efficiency can scarcely exceed 20 per cent. Hence the maximum potential efficiency from the apparatus proposed is $^1/_3 + (0.2 \times ^2/_3) = 46.7$ per cent.

The exhaust-gas heat has the desirably high temperature. Transmission from dry gas is slow and transmitting apparatus may be (as with hot-air engines) hard to maintain, but experience with economizers has shown these objections not to be fatal. A transmitting surface of 3 sq. ft. per hp. of the internal-combustion cylinder should be sufficient.

The jacket heat exists at low temperature and hence at low availability. The proposed engine increases the temperature and further increases availability by using the exhaust gas. The jacket heat (except for radiation) is all reclaimed. The exhaust heat is reclaimed to the extent represented by a temperature drop from 900 deg. to 150 deg. Unfortunately, 80 per cent of these reclaimed amounts must immediately be thrown away to the steam-plant circulating water.

A steam generation of 7 lb. per b.hp-hr. can scarcely be expected. Under the illustrated conditions, this implies a jacket loss of about 6300 B.t.u. per hr., or $2^1/_2$ times the normal.

The general idea is sound, but it makes the further extended development of the gas engine contingent on some radical improvement in the economy of the steam engine.

W. D. Ennis.

New York, N. Y.

The First Steamship to Cross the Atlantic

To the Editor:

In the June number of Mechanical Engineering, on page 554, there is an article entitled The Crossing, which states than "On May 26, 1819, an American ship, the *Savannah*, was the first steam-driven vessel to cross the ocean, etc."

As a matter of history the *Savannah* did not make the entire voyage under steam. As stated in the Encyclopedia Britannica, "She was fitted with sails, and used them in rough weather, unshipping her paddle boxes."

I give below extracts from the Toronto *Daily Star* treating on this very matter which I think should be put before the Society.

A letter recently appeared in the London *Times* from Prof. W. H. Vander Smissen, of the University of Toronto, now resident in England, in which he pointed out that it was neither the American-owned *Savannah* nor the British steamship *Sirius* or *Great Western*, but the Canadian-owned and built *Royal William* which was the first vessel propelled by steam to cross the Atlantic.

From time to time disputes have arisen on this question, and Professor Vander Smissen recalls that in 1894 the Earl of Aberdeen, as Governor-General at the time the Intercolonial Conference was in Ottawa, unveiled a tablet placed on the wall of one of the corridors of the Parliament Buildings inscribed with the details of the *Royal William's* performance. The burning of the buildings early in the war destroyed this tablet, which it is hoped will be replaced. Professor Vander Smissen says that the *Royal William* was designed by Mr. James Goudie, a native of Quebec. Her builders were Messrs. Campbell and Black, of that city; she was engined in Montreal, and before making her memorable trip from Quebec via Picton, N. S., to London, in August, 1838, had traded between Quebec, Halifax, and Boston. She was bought by the Portuguese Government and renamed, and later served as a Spanish warship under the name *Isabel Segunda*. She had a length of 176 ft., a width between the paddle boxes of 28 ft., and a gross tonnage of 1,370.—*Toronto Daily Star*, May 7, 1919.

It was in 1833 (not 1838, as previously stated) that the *Royal William* made her famous voyage, and she was not only the first ship to cross the Atlantic under steam, but the first to be built with a system of water-tight compartments and the first war steamer that ever fired a shot. This was in 1836, after she had been sold to the Spanish Government and was being used (under the name *Isabel Segunda*) in operations against Don Carlos

The origin of the Canadian steamer which thus has a triple distinction in marine history is rather interesting. Influential men who in 1821-24 wished to bring about a union of the North-American Provinces were met with the objection that there was really no inter-Provincial trade. As a result of the discussion subsidies were offered by the Legislatures of Lower Canada and Nova Scotia for steamship communication between Quebec and Halifax. Citizens of the two cities formed a joint stock company, and the *Royal William* was built in 1830-31 at Quebec at a cost of about $80,000. She was fitted with 200 hp. engines at Montreal, and in August of 1831 steamed from Quebec to Halifax with 90 passengers, 120 tons of coal, and some other freight. In 1833, after being sold to satisfy a mortgage, she left Quebec for London, Eng., via Picton. The voyage from the latter port to Gravesend lasted from August 18 to September 11, and steam was utilized the entire distance.—*Toronto Daily Star*, June 14, 1919.

To this it may now be added that two Britishers on June 15, 1919, made the first trip from Newfoundland to Ireland successfully by aeroplane.

James Milne.

Toronto, Ont.

James Watt Centenary

On August 25 one hundred years will have elapsed since the close of James Watt's life.

In honor of this centenary the engineers of Birmingham, England, the city of Watt's adoption, where his most important work was accomplished, are to provide permanent memorials. These are to consist of (1), the endowment of a professorship of engineering to be known as the James Watt Chair at the University of Birmingham, for the promotion of research in the fundamental principles underlying the production of power and the study of the conservation of the natural sources of energy; (2) the erection of a James Watt memorial building which shall serve both as a museum for examples of the work of Watt and his contemporaries, and as a meeting place and library for scientific and technical societies; and (3) the publication of a memorial volume.

Inasmuch as the benefits which the genius of James Watt bestowed on mankind are too widespread for any purely local celebration, the exercises in connection with the establishment of the memorials will be of an international character, with representatives from various organizations in different countries.

The representative of The American Society of Mechanical Engineers will be Mr. W. E. Symons, Chairman of the Finance Committee of the Society, who is now on his way abroad. A further announcement will probably be made in a later issue.

In his work throughout the country in behalf of discharged service men Colonel Arthur Woods, Assistant to the Secretary of War in charge of finding employment for demobilized soldiers, sailors and marines, has learned that in many sections people generally do not know just what the Government is doing to enable men disabled in the line of duty to reëstablish themselves in civil life. The authorized agency of the Government for carrying on this work is the Federal Board for Vocational Education, which is charged by Congress with the "vocational training of disabled soldiers and the placement of rehabilitated persons in suitable and gainful occupations," after their discharge from the Army.

Disabled men should accordingly get in touch with this Board which will place them in educational institutions, where suitable trades or occupations will be taught them according to their individual experience, capacities and preferences. A disabled man so incapacitated that he cannot take up his old occupation will be allowed to choose any occupation or trade which he thinks he would like to follow, subject, of course, to approval by the Board, which is interested only to be assured that the man is fitted to pursue the occupation or trade elected.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

Coöperation in Research by Government of Great Britain

THE following letter indicates action of the British Government in aiding research and is given for the information of the membership of the Society:

EDITOR MECHANICAL ENGINEERING,
29 West 39th Street, New York.

Dear Sir:

The action of the British Government, which has placed a fund of £1,000,000 at the disposal of the Research Department to enable it to subsidize industrial research, should be of interest to mechanical engineers and manufacturers.

The opinion is held in some quarters that we have been ahead of Great Britain in the matter of research work. The work of our Agricultural Department, Bureau of Mines and Bureau of Standards are held up as models of Government Research, and the work of the Altoona Locomotive Testing Plant of the Pennsylvania R.R., the Nela Park Laboratories of the General Electric Company and the laboratories of the Eastern Kodak Company, to select a few examples which occur to me, are held up as models of research work by private industrial companies.

The British system looks to the coöperation of Government and private effort. Thus, to select an example, instead of our Bureau of Mines making a more or less independent study of the combustion of coal in various types of furnaces and on various types of grates or stokers, the British idea is that such work should be done by an association composed of grate and stoker manufacturers aided financially by the Government. Each firm contributes a certain amount of money to its association and naturally has a voice in determining the problems to be studied. The Government supplies a certain aid or subsidy to the association, also exemption from taxation on funds contributed by individual companies.

At first it may seem that such an arrangement would be superior to our own because the work undertaken would conform more nearly to the immediate and pressing needs of the manufacturers. But, viewing the problem in its broad aspect and from the standpoint of future wealth and prosperity of the nation, it does not necessarily follow that all research work should be intensely commercial, that is, directly trained upon a pressing commercial problem. Many of the most valuable scientific discoveries have been made by men who were working purely in the search for truth and without any definite commercial object.

Our great national research organizations might therefore confine their efforts to work which has a less definite commercial value, while the more pressing problems could be handled by research associations after the British pattern and also, of course, by individual research work in each plant. This would make three links in the chain of research work. The work of the various research bodies could be coördinated or harmonized by suitable councils. Such bodies would recognize problems of a more purely scientific nature to be undertaken by the national bodies which have grown out of and are suggested by the more pressing commercial problems being studied by the research associations, or, on the other hand, recommend problems for study by the associations which have grown out of more general investigations made by the national organizations. To return to the example of the combustion of coal: elaborate studies of how coal is burned on grates and stokers are bound to suggest ideas for the design of a better stoker. Such a problem cannot be investigated further, however, by a purely government body, because it involves invention and patent rights. The British idea is to have such work done by a coöperative association of manufacturers and any patent rights become the property of the association, subject only to a few limitations, such as approval of foreign license. If the Government controlled inventions an undesirable, not to say dangerous, clash between industry and Government might eventually arise.

I am attaching the draft letter concerning the conditions as to the payment to research associations by the British Government.

Very truly yours,
(*Signed*) PAUL BANCEL.

New York, May 12, 1919.

Labor and Scientific Research

The American Federation of Labor at its Atlantic City meeting adopted a series of resolutions advocating scientific research as the basis for increased productivity in the industries and the promotion of the health and well being of employees. These resolutions, the most important of which were printed on page 625 of MECHANICAL ENGINEERING for July, call attention to the numerous pressing problems whose wise solution depends upon scientific and technical research, and to the overwhelming importance of science and technology to the national welfare whether in war or peace.

A—RESEARCH RESULTS

Cement and Other Building Materials A3-19 Roofing Materials, Specifications for plastic cements having troweling and brushing consistency for coal tar, pitch and asphalt from experiments. Address Director, Bureau of Standards, Washington, D. C.

Cement and Other Building Materials A4-19 Effects of Fine Grinding of Portland Cement. Cement ground 99 per cent fine when used in concrete mixtures of varying proportion at age of 7 days gave increase of strength ranging from 15 to 61 per cent of concrete of normal fineness. Tests of 28 days 3 months, 6 months and one year are in progress. Address Director, Bureau of Standards, Washington, D. C.

Cement and Other Building Materials A5-19 Reinforced-Concrete Beams. Recent tests of beams failing by compression on upper side indicate that ultimate compressive strength of concrete is considerably greater when tested in form of beam than when tested in the form of prism under uniformly distributed load. This fact gives promise of forming a reliable basis for increase in safe working stress in compression. Work is now being carried on regarding shearing stresses in beams. The work was conducted in connection with the design of reinforced-concrete ships. Results indicate that much larger web reinforcement may be more advantageously used than that hitherto deemed permissible. Address Director, Bureau of Standards, Washington, D. C.

Heat A1-19 Heat-Transfer Rate in Boiler Tests. Experiments on the rate of heat transfer from a hot gas through a cooler metallic substance. Babcock & Wilcox Company, 1916. The results of these experiments are given in a book of 84 pages published by the Babcock & Wilcox Company, New York. The heat-transfer rate in B. t. u. per hour per deg. fahr. temperature difference per sq. ft. is given by the formula

$$R = a + b\ (W/A)$$

where W = weight of gas passing through absorbing surface per hour, in lb.

A = area of cross-section through which gas passes, sq. ft.

The value of a is 2.0; b is 0.0014 in general, although it changes with temperature as shown by Figs. 1 and 2.

The temperature difference to be used is given by

$$\text{Temp. Diff.} = \frac{\Delta T_1 - \Delta T_2}{\log_e (\Delta T_1 / \Delta T_2)}$$

where ΔT_1 and ΔT_2 are temperature differences between gas and steam at entrance and exit. Figs. 1 and 2 show the plotted results for values of R with ordinary tubes and for annular channels.

Electric Power A2-19 The Present Development of Transmission Lines in Kansas, by F. Ellis Johnson, University Experiment Station, University of Kansas, Lawrence, Kan. Address Director A. A. Potter. This Bulletin describes the growth of transmission lines, their origin, agreements, service to farmers, popular feeling, industrial power lines, agricultural lines, construction features and economy.

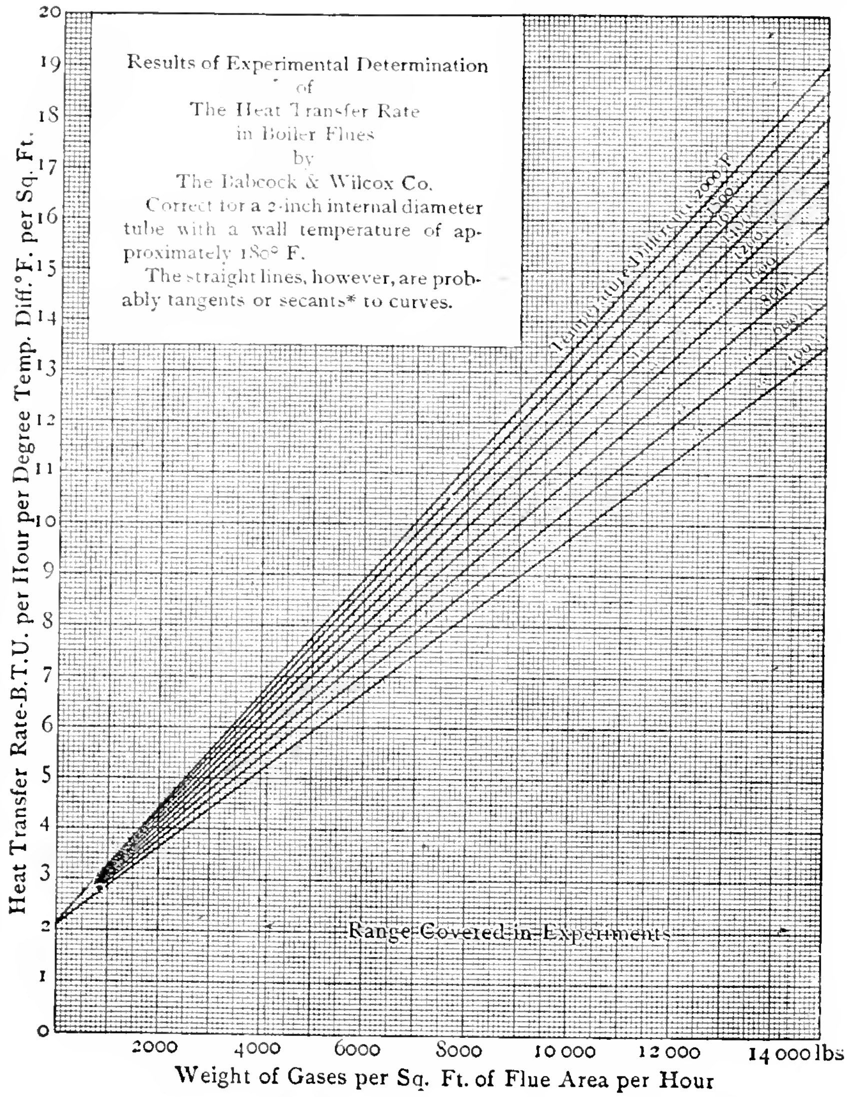


Fig. 1 Heat-Transfer Rates for 2-in. Boiler Tube

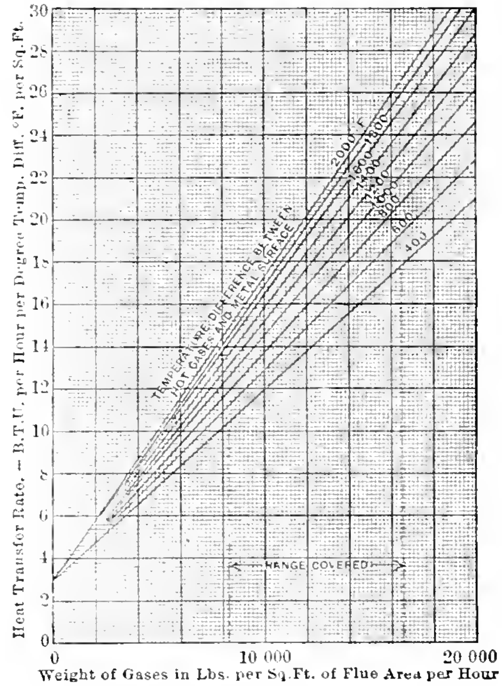

Fig. 2 Heat-Transfer Rates for Tube 2 in. in Internal Diameter Fitted with a Core 1 in. in External Diameter

Leather and Glue A1-19 Linoleum Cements. Investigation on linoleum cement showing that shellac cements with alcohol as thinner with and without finely powdered mineral filler were more waterproof and held linoleum more tenaciously to concrete or steel than those cements made from dextrin or other water-soluble gums or some other resins cut in alcohol. Shellac cement with mineral filler adhered more tenaciously and did not become brittle or dry as that without filler. When water-soluble pastes are used a strip 1 ft. on either side of seam should be cemented with waterproof cement. Address Director, Bureau of Standards, Washington, D. C.

Metallurgy and Metallography A4-19 The Relation of the Phase Changes to Microstructure in the Heat Treatment of Aluminum Bronze, by L. R. Seidell and G. T. Horvitz. See *Chemical and Metallurgical Engineering*, or address New York Testing Laboratory, 51 E. 42nd St., New York.

Metallurgy and Metallography A5-19 The Relation of Quenching Temperature to the Microstructure in High-Speed Steel with Effect on Physical Properties. Paper to be read before American Steel Treaters' Society. Address New York Testing Laboratory, 51 E. 42nd St., New York.

B—Research in Progress

Apparatus and Instruments B7-19 Diaphragm Indicator for Internal-Combustion Engines. Development work is being carried on by the Bureau of Standards on an indicator for gas engines at high rotational speed with a diaphragm indicator with beam of light. Address Director, Bureau of Standards, Washington, D. C.

Apparatus and Instruments B8-19 Bourdon Gages for 30,000 lb. per sq. in. A study of the performance of two Bourdon pressure gages for 30,000 lb. per sq. in. with reference to drift of indication.

Apparatus and Instruments B9-19 Abrasion Machines. Investigation to determine relationship, if any, which exists between abrasion test on Deval machine when using shot and when no shot are used. By R. A. Seaton, Engineering Experiment Station, Kansas State Agricultural College, Manhattan, Kan.

Cement and Other Building Materials B4-19 Reinforced-Concrete Beams. Recent tests of beams failing by compression on upper side indicate that ultimate compressive strength of concrete is considerably greater when tested in form of beam than when tested in the form of prism under uniformly distributed load. This fact gives promise of forming a reliable basis for increase in safe working stress in compression. Work is now being carried on regarding shearing stresses in beams. The work was conducted in connection with the design of reinforced-concrete ships. Results indicate that much larger web reinforcement may be advantageously used than that hitherto deemed permissible. Address Director, Bureau of Standards, Washington, D. C.

Cement and Other Building Materials B5-19 Reinforced-Gypsum Beams. Standards of design for beams and floors with gypsum in connection with Committee C 11 of the American Society for Testing Materials. Bureau of Standards. Address Director, Bureau of Standards, Washington, D. C.

Cement and Other Building Materials B6-19 Run-of-Pit Gravel for Concrete Without Use of Other Aggregate in Kansas. Engineering Experiment Station, Kansas State Agricultural College. Address Dean A. A. Potter, Manhattan, Kan.

Cement and Other Building Materials B7-19 Sand-Cement Concrete Without Coarse Aggregate. A research to determine at what price crushed stone can be used. A study for localities where little coarse aggregate is available. Engineering Experiment Station, Kansas State Agricultural College. Address Dean A. A. Potter, Manhattan, Kan.

Cement and Other Building Materials BS-19 Use of Joplin Chats as Concrete Aggregate in Coarse or Fine Condition. Engineering Experiment Station, Kansas State Agricultural College. Address Dean A. A. Potter, Manhattan, Kan.

C—Research Problems

Glass and Ceramics C1-19 Enameling by the Use of Colloids instead of Petroleum Solvents. General Efficiency Department, Chevrolet Motor Company, Tarrytown, N. Y.

D—Research Equipment

Aircraft D2-19 Propeller Dynamometer. Designed for 14 lb-ft. torque, 60 lb. thrust and 5600 r.p.m. to test model air propellers in large wind tunnel through variable-speed motor of 15 hp. capacity. Address Commander McEntee, Navy Yard, Washington, D. C.

Aircraft D3-19 Research Facilities at the Curtiss Engineering Corporation. The Curtiss Engineering Corporation is situated conveniently near New York City, the aviation fields and the bays of Long Island, at Garden City, L. I. The plant is primarily an experimental plant and is devoted to aeronautical research in all forms. Address Research Laboratory, Curtiss Engineering Corporation, Garden City, L. I. (See Research Personal Notes. *Aircraft E1-19*, for private use of this laboratory.)

Equipment. The plant with all manufacturing facilities.

Research Department. This department has three wind tunnels in operation:

One large Eiffel-type wind tunnel recently completed, run by a 400-hp. gasoline motor, electrically controlled. The experimental chamber is an improvement on all existing types. The experimental chamber is 15 ft. long, 13 ft. wide, and about 20 ft. high, and the cross-section of the air stream at the balance is 7 ft. Speeds up to 100 m.p.h. are now obtainable and shortly will exceed this value. The balance is a specially designed one of the unipivot type sensitive to less than 0.0001 lb. of wind force.

One 4-ft. wind tunnel of the enclosed type improved, actuated by a Curtiss OX motor and an especially designed air-turbine propeller; a special Curtiss-type wind-tunnel balance is used. Air speeds up to about 80 m.p.h. are available in this tunnel.

One 2-ft. wind tunnel for qualitative work, run by an electric motor giving wind speeds around 30 m.p.h.

A completely equipped model-making and instrument-making shop. This shop is equipped with three lathes (one of great precision and all electrically driven), one jointer, one hand saw and a wood-turning lathe, and a number of special apparatuses to facilitate the work of model making.

Research Work. The Research Department undertakes any special investigation of a theoretical nature required. Wind-tunnel tests of all kinds are carried out in these tunnels by a competent staff. Tests on new wing sections at various speeds, tests on new models giving stability and performance before the full-size machine is built or flown make for the utmost safety in the work. Tests on stream-line forms such as fuselages, dirigible shapes, flags, propellers, gasoline pumps, generator turbines, etc., are being made continually.

The Curtiss Aeronautical Library is a very complete collection of aeronautic literature in all languages. It subscribes to all aeronautic periodicals of any importance.

Chemical and Materials and Heat-Treatment Laboratories. These laboratories are equipped to test all materials entering into airplane construction.

Staff of Research Department. J. P. Tarbox, Director, Dr. J. G. Coffin, Assistant Director and Physicist, and three to five technical research engineers and a librarian. The model shop employs a corps of expert model makers.

Staff of Chemical and Material Laboratories. Mr. Frisbie, Mr. Crossley, Chemist.

Research Time. All of the work in general is of a research nature. About one-half is devoted to pure research.

Automotive Vehicles and Equipment D1-19 Equipment, Personnel and Problems of the Packard Engineering Laboratory. Address Packard Motor Car Co., Engineering Executive, Detroit, Mich.

Equipment. The equipment is divided into two classes, motor-testing equipment and bench-testing equipment. The motor-testing equipment consists of three electric cradle-type dynamometers, one for high-speed passenger-car work up to about 100 hp. and 3500 r.p.m., an airplane-engine dynamometer capable of carrying 400 hp. continuously and over 500 hp. for a brief period for speeds up to 2000 and 2200 r.p.m. maximum, and a truck-engine dynamometer to take care of heavy torques at low speed and capable of carrying about 60 hp. at 1000 r.p.m. The accessories of these three dynamometers are practically identical. The grids of the absorption resistance are located in a separate room and the heat is carried away by forced draft.

In laying out the dynamometer room proper the chief point was to eliminate all possible obstructions above ground in the way of piping and wiring in order to preserve a clean room free from excessively high temperatures or noxious gases so that the operators would have the best of surroundings and be able to concentrate on the problems at hand. This layout permitted of a maximum amount of daylight, which is very desirable for accurate work. The exhaust system is taken care of by underground tunnels connected to a 10-hp. electric fan located outside of the room and communicating with a stack extending above the roof. Communication between the engine exhaust pipe and the exhaust tunnel is afforded by a standard manhole cover into which suitable lengths of flexible steel tubing are screwed for connection to the exhaust pipe of the engine. For airplane-engine work exhaust stacks are used which discharge into suitable sheet-iron exhaust boxes which take the place of the manhole cover so as to present a minimum obstruction to the free exit of the exhaust gases.

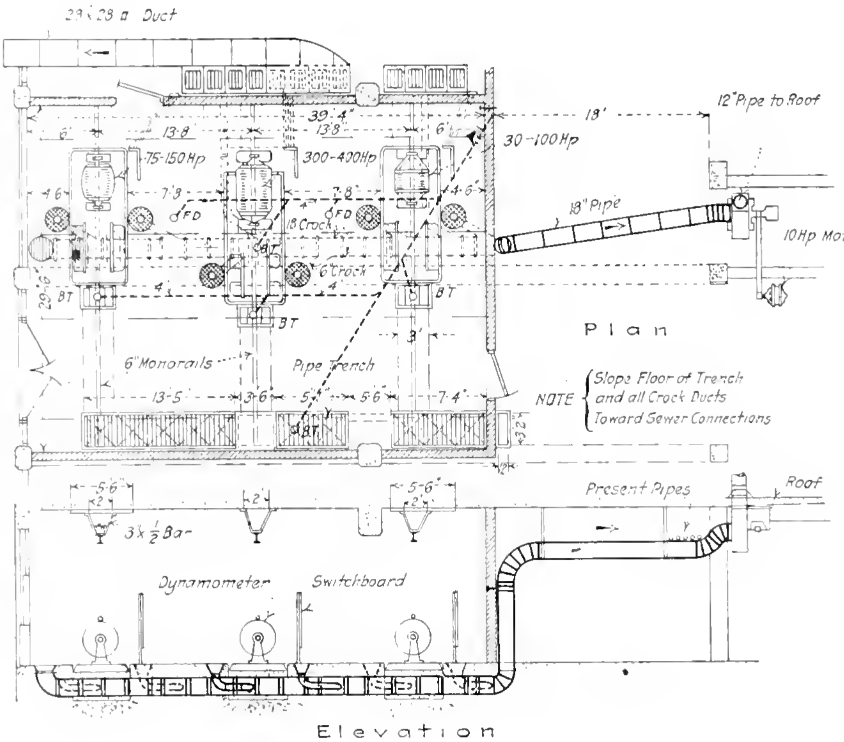

Fig. 3 Plan and Elevation of Packard Laboratories for Heavy Motors

Gasoline is delivered to the dynamometer room by the remote-control Bowser system with a meter located in the dynamometer room. Two gasoline tanks are provided at an elevation of about 8 ft. from the floor, one of which is mounted stationary and the other is fixed on the platform of a sensitive balance. Gasoline feed pipes to the three dynamometers are run in roomy tunnels under the floor, and by a system of six valves it is possible to feed any one of the three dynamometers from either the fixed tank for ordinary runs or from the tank mounted on the scales for economy tests.

Water piping and the water system are underground as far as possible, a 25-gal. tank being located in each of the three tunnels leading to the respective dynamometers. Suitable hot- and cold-water connections are made to this tank and controlled by valves the handles of which project above the floor. Access to these tunnels is provided by hatchways which are readily removable. The entire piping and tunnel layout is clearly shown in Fig. 3.

Ample bench room is provided to do the minor fitting work required in work of this character. Dynamometer readings consist of speed

and torque readings. Speed readings are taken by carefully calibrated tachometers and checked by positive counters. Torque readings are taken by means of springless scales and checked by tare beam. Specially designed dynamometer couplings are used to take care of slight misalignments. A uniform system of engine controls is mounted on each dynamometer so as to be readily adaptable to any kind of engine. A trolley runs over each dynamometer and a chain hoist is used for mounting and dismounting the engines. The airplane dynamometer has in addition to its gasoline and water feeds an oil-circulating feed, the oil being returned to a tank mounted on a sensitive scale adjacent to the gasoline scale. Oil consumption of truck and car motors is arrived at by separate portable apparatus which involves the use of a small oil pump driven by an electric motor and an oil reservoir mounted on a sensitive scale. The engine being tested with latter apparatus is run with a dry sump. See Fig. 4.

Compressed air, suitable sockets for electric drills, hot and cold water, 6-volt battery current, etc., are all piped to the front of each dynamometer for purposes required in various tests.

The bench-dynamometer room (Fig. 5) is intended for all tests other than motor-power tests and its equipment is of growing and varied nature. It is not necessary to describe in detail each piece of apparatus but the diversity of tests can be judged by the following list:

1 Endurance tests on plain and ball bearings.

2 Endurance tests of magnetos, generators, starting motors, fans, oil pumps, air pumps, tire pumps, camshaft drives, universal joints, and many other accessories which are submitted from time to time. In this connection the object is to provide in each case a more or less permanent set-up so as to be available for a repetition of the test at any time in the future.

3 Calibration of radiators to determine their efficiency alone and in conjunction with various water pumps and fans.

4 Storage-battery characteristics.

It can be readily realized that the above list does not by any means comprise all the various experiments which come under the general heading of bench tests. It is also impossible to start out with a laboratory for this work fully equipped since the very nature of the work demands the designing of new equipment from time to time. A comprehensive switchboard for electric-motor speed control has been worked out for all the motors used in this room and some such system is essential to do accurate work of this nature. In general each piece of apparatus is directly connected to an electric motor and in no case is a belt or any other form of a friction drive used. Direct current (220 volts) is used and the field and armature connections from each motor are brought to a common switchboard. A bank of cast iron grids is connected across the line and 220 equally spaced taps off of these grids are connected to a special dial switch. By means of suitable plugs similar to a telephone switchboard any motor in the room can be connected to this dial switch and in this manner its speed variation can be controlled very closely since the increments of voltage supplied to the armature or field differ by only one volt. When the proper speed has been reached for any particular run the proper plug connection is made and the dial switch is again free to use with any other motor.

Another room is provided into which cars and trucks can be run for such special work or inspection as may be desired.

Personnel. The dynamometer-room personnel consists of a foreman with about twelve men with particular experience for this class of work. This demands a thorough understanding of all engines and a fair amount of mechanical skill of a wide nature. The office force consists of four engineers and a man to take care of the clerical and stenographic work. The work is generally divided among the engineers in a manner to develop specialists. One man, for example, will concentrate on the getting out of reports, another man will supervise bench tests, another man will do the necessary designing of all the apparatus required and concentrate on calculations, etc. A cast-iron rule is that a record be kept of every experiment whether successful or not.

Problems. The problems presented generally can be classed as follows:

1 Routine Work. This is generally a matter of proving out certain elements in a new design and for the most part present no difficulties since it is generally a comparison between an old design and a new one. These tests, of course, cover a very wide range, some might take but a few minutes and others might stand over a period of several months.

2 Factory Troubles. All tests pertaining to factory troubles are given precedence over all other work and these generally consist of troubles which do not manifest themselves until wholesale production of a certain design is gone into. Work of this character demands the utmost concentration and all possible speed.

3 Research Work. This work generally contemplates improvements in the product which are not essential for immediate production and which are of such a character as not to permit of their solution on the drawing board. This work is used as a filler-in proposition and generally jobs coming under the previous headings have precedence over this work. A certain amount of design work is necessary to carry on these researches and this necessitates the co-operation of the other Engineering Department.

No work is undertaken by this Department unless the Engineering Executive gives his authority and reports are given him from time to time showing the progress made on various tests. In case of a conflict as to the precedence of various tests, appeal is made to the Engineering Executive. This department also controls all road testing and aims to have on the road a car or truck for day and night running at all times. These cars operate over carefully-laid-out routes with competent crews for operation. Careful reports are kept of all incidents affecting the tests.

In general it is the aim of this department to insure that all defects in apparatus undergoing tests should be brought to light and viewed from this light its responsibilities are great. The vast amount of money spent by all automobile concerns in service and free replacements can be greatly diminished by the use of suitable testing equipment and it is felt that this aspect is being realized more all the time. The fact that so many points in design can be definitely proven to be good or bad by accelerated test is of the utmost importance in proving out a design. An engine for instance can be run for 24 hours a day at a speed of 60 miles per hour on the dynamometer and in this manner an astonishingly high mileage can be secured in a very short time. Of course, good judgment must be exercised in making these tests since under certain conditions they can be very much more severe than will ever be encountered in service, but in general the only disadvantage from going by an accelerated test is that the factor of safety may be too high and the particular part may be too heavy or too expensive.

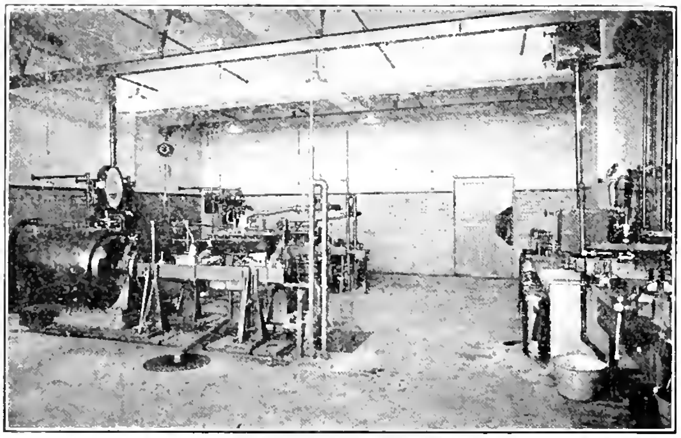

FIG. 4 PACKARD LABORATORY FOR HEAVY MOTORS

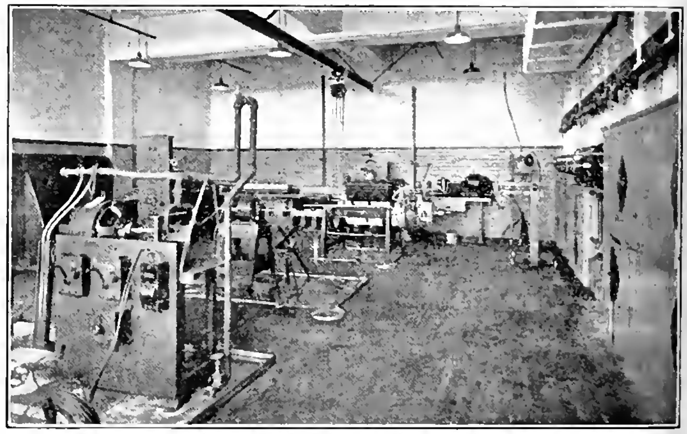

FIG. 5 PACKARD LABORATORY FOR SMALL DYNAMOMETERS

Curtiss Engineering Corporation D1-19 Description of equipment and personnel under *Aircraft D3-19*.

Detroit Testing Laboratory D1-19 Chemical and physical apparatus, testing machines for strength, hardness, impact, metallographic equipment. High-temperature furnaces and pyrometers for heat treatment of metals, chemical processes and oil production from shale.

The James H. Herron Co. D1-19 Laboratories equipped for chemical analysis, physical tests, metallurgical and metallographic work, 500,000-lb. universal machine, 200,000 lb. compression machine, Brinell hardness tester, Shore hardness tester, metallographic equipment for ferrous and non-ferrous metals, crucible, open-hearth and electric furnaces

heat-treatment apparatus. The laboratory works in iron, steel, bronzes, brass, bearing metals, clays, refractories, enamels, fuels, oils and lubricants. The work of research for development is one feature of the laboratory. Address James H. Herron Co., Cleveland, Ohio.

Robert W. Hunt Company D1-19 Laboratory for commercial testing for clients. Address Robert W. Hunt Co., Chicago, Ill. The general equipment of the physical testing laboratory is as follows:

- Riehlé horizontal testing machine fitted with 200-lb. and 1000-lb. spring balances
- Riehlé vertical-screw machine, 50,000 lb. capacity. Maximum sizes taken: 6 ft. on tension tests, 20 in. on compression tests, and 16 in. on transverse tests
- Riehlé vertical-screw machine, 30,000 lb. capacity. Maximum sizes taken: 5 ft. on tension or compression tests, 8 ft. on transverse
- Riehlé vibratory machine for staybolt iron
- Standard brick rattler
- Standard Deval abrasion machine
- Bausch & Lomb microphotographic outfit
- Gas furnace and LeChatelier pyrometer
- Shore scleroscope
- Standard Tyler sand sieves
- Stone sieves, size 2 in. — ¼ in.
- Completely equipped chemical laboratory. Rotary cement kiln, ceramic furnace for shales and clays, and apparatus for melting points to 3000 deg. fahr.

Kansas State Agricultural College, D1-19 Equipment for Research.

Material-Testing Machines

- 50,000-lb. Riehlé universal testing machine
- 100,000-lb. Riehlé universal testing machine
- 200,000-lb. Olsen universal testing machine adapted to beams to 20 ft. span and columns of 15 ft. high
- 250,000-lb. torsion testing machine
- Upton-Lewis toughness-testing machine for reversal of stress
- Shore scleroscope for hardness
- Brinell hardness machine
- Bausch & Lomb metallurgical microscope

Laboratories

- Cement laboratory
- Concrete and aggregate laboratory
- Road-materials laboratories for non-bituminous and bituminous materials
- Hydraulic laboratory with weirs, orifices, tanks, pumps, rams, turbines, meters, pipes and fittings.

Lincoln, Hanson & Abbott D1-19 Laboratories of Lincoln, Hanson & Abbott, Portland, Me., equipped for standardizing instruments, testing transmission systems and central stations, investigations of high voltage, and with apparatus for making tests of materials for underwriter's requirements. Laboratories also equipped for photometric measurements. The equipment is complete for all kinds of electrical investigations.

Marine Engineering D1-19 Ship Model Basin. Experimental model basin, Navy Yard, Washington, D. C., 380 ft. long, 40 ft. wide and 14 ft. deep with tow carriage carrying resistance dynamometer and other measuring apparatus. Capacity of dynamometer, 450 lb. maximum. Speed of carriage, 18 knots (or 30 ft. per sec.). Basin is equipped for measuring rolling and pitching. For shallow-water experiments false floor can be installed. Apparatus for producing waves in basin is installed. Propellers of 16 in. in diameter or 6 in. in diameter may be tested at this plant. Address Commanding Officer, Department of Construction and Repair, Navy Yard, Washington, D. C. See Research Personnel Notes, *Marine Engineering, E1-19*, p. 537 of June issue, for use of above in interest of private parties.

Metallurgy and Metallography D3-19 Electric Furnaces. Northrup Ajax furnace operated with alternating current of from 10,000 cycles per second, giving temperature within an inductor coil of 2500 to 2800 deg. cent. Furnace of special value in obtaining carbon-free melts. Address Pyrolectric Instrument Co., Trenton, N. J.

Packard Motor Car Company D1-19 Research Laboratory. See *Automotive Vehicles and Equipment D1-19*.

New York Testing Laboratory D1-19 Organization composed of graduate chemists and metallurgists with wide experience in the manufacture of iron and steel, furnaces, foundry practices for ferrous and non-ferrous metals, forging practices, heat treatment, physical tests, impact, metallographs, analyses. Address New York Testing Laboratory, 51 E. 42nd St., New York.

Henry S. Spackman D1-19 Private Laboratories of Henry S. Spackman Engineering Company, 2024 Arch St., Philadelphia, Pa. Specially equipped for chemical and physical tests of cement, concrete, steel, iron and alloys.

Enrique Touceda D1-19 Laboratory of Enrique Touceda, Albany, N. Y. Laboratory well equipped for physical and chemical properties of ferrous and non-ferrous metals and alloys. Structural composition and heat treatment. Laboratory well equipped for special research. Analytical investigations of a routine nature are made. Address Enrique Touceda, Albany, N. Y.

E—Research Personal Notes

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

SUBJECTS OF THIS MONTH'S ABSTRACTS

FACTORY MANAGEMENT

The Silent Watchman Over Industry. The necessity of plant protection against human destructive agencies has been forcibly emphasized by various occurrences during the period of the war, but even in times of peace there is an essential need of adequate protection for plants.

The article briefly discusses the problem of fire protection and then goes into considerable detail as to protection by fencing in the premises. Such fencing-in protects the plant against trespassers, with all the danger that they involve in the way of theft and increased possibility of fire.

Many types of fences designed to give plant protection are on the market. During the war the amount of such fencing sold to industrial plants was very large. In some instances the Government itself paid for the fencing, while in other cases it refused to award contracts until the fencing was installed by the company itself. The cost of fencing may be as high as $2 a lineal foot.

In addition to fencing, flood light was extensively used during the war. It has been estimated that during 1917 and 1918 some 100,000 flood lights were sold to American plants for protection purposes, but the sales fell off tremendously after the signing of the armistice. (*The Iron Trade Review*, vol. 64, no. 25, June 19, 1919, pp. 1609 to 1612, 6 figs., *g*)

FOUNDRY

A Permanent Mold or a New Method of Molding, F. B. Gordon. The author begins by justly pointing out that our modern methods of molding are to all practical purposes the same as those which were practiced by the Egyptians 4000 to 5000 years ago. From this he proceeds to a brief description of a discovery by William M. Hoffman, of Buffalo, N. Y., who claims that he has found a new molding material.

While exploring corundum veins in the Blue Ridge Mountains of North Carolina, he came upon a surface of combination amphibole and actinolite.' These minerals belong to the same class as asbestos, with the addition of magnesia and other minerals of a refractory nature. It is claimed that with a proper binder, which is said to have been perfected, it is possible to use these materials for permanent molds. No data as to the method of using such molds, their life and way of restoring the mold face are given in the original article. (*Canadian Foundryman*, vol. 10, no. 6, June 1919, p. 147, *d*)

FUELS AND FIRING

The Alcohol Fuel Committee's Report. Abstract of the report of the Alcohol Fuel Committee appointed in October 1918 by the British Government.

The Committee consisted mainly of the nominees of Government Departments, not necessarily fuel experts, but appointed to survey the situation, to estimate the importance of the problem and to report as to the best steps to be taken.

The report indicates that the climate in Great Britain is not well suited to the growth of most alcohol crops, but that synthetic production of alcohol is a commercial possibility. A spirit can be obtained from ethylene extracted from coal and coke-oven gases and it is estimated that the production of 100,000,000 gal. a year might be reasonably expected in Great Britain if the necessary facilities were given for the development of the method.

The statement is made, however, that the main sources of power alcohol must be found in the vegetable world in tropical and subtropical countries.

The main conclusions of the report are that in order that the fuel may be available in quantities and at the right price, a material change must be made in many government regulations. The use of cheaper denaturants must be permitted, continuous distillation must be allowed and also simultaneous fermentation and distillation in the same building. These changes would occasion the abandonment of the present regulations for ascertaining specific gravity before fermentation.

The report also recommends the establishment by the government of a permanent organization to initiate and supervise experimental and practical development work on production and utilization of power alcohol. (*Motor Traction*, vol. 29, no. 748, July 2, 1919, pp. 5-6, *g*).

German Experience with Coke Firing of Boilers During the War

Coke Firing, Reichelt. Data on the present state of knowledge of coke firing in Germany, embodying apparently experience gained during war.

It is pointed out that a clear distinction should be made between gas coke and metallurgical coke. Gas coke is easier to ignite because its structure is less compact, while coke from coke ovens, especially that made from fat coals, has a compact structure and is less easy to ignite.

When burned, coke keeps the shape of the lump longer than coal. Coke is more difficult to bring to the state of incandescence, but it burns slower. It does not give off its heat with the same speed as coal and because of this, in order to burn the same weight of fuel one has to employ a larger grate and use a deeper fuel bed; its lower specific weight as compared with coal also makes a larger grate necessary.

The size of the lumps is essential. If the lumps are too large, the surface subject to the action of the air is too small to maintain the combustion process, at least if the draft remains within

the same limits. Metallurgical coke as it comes is usually in too large lumps. It is pointed out that the users of coke cannot be expected to crush it, as under present conditions it is impossible to secure crushing equipment, so that the coke should be crushed at the plants. The limits of size are indicated by the author as 10 mm. (0.4 in.) on the one hand to 40 mm. (1.6 in.) on the other.

The finer sizes, and in particular coke breeze, make too dense a layer and with ordinary draft do not provide for a sufficient contact with the air. Their combustion on a plain grate is possible only when special appliances are used.

As a rule, coke requires a stronger draft, which is due to the greater depth of the fuel bed and the resulting increased resistance to the flow of air.

The portable boilers easiest to equip for coke combustion are of the locomotive type, because of the powerful draft available. As a rule, in locomotive operation coke is mixed with coal in the ratio of 1 to 2.

Otherwise coke is but little adapted for portable boilers because of the lack of suitable draft.

For use on shipboard coke is likewise not well suited because the ship bunkers cannot take up as much coke as they would coal. Furthermore, coke is not as convenient as coal where operation of the boilers is of an intermittent character, as it is in river- and canal-boat transportation.

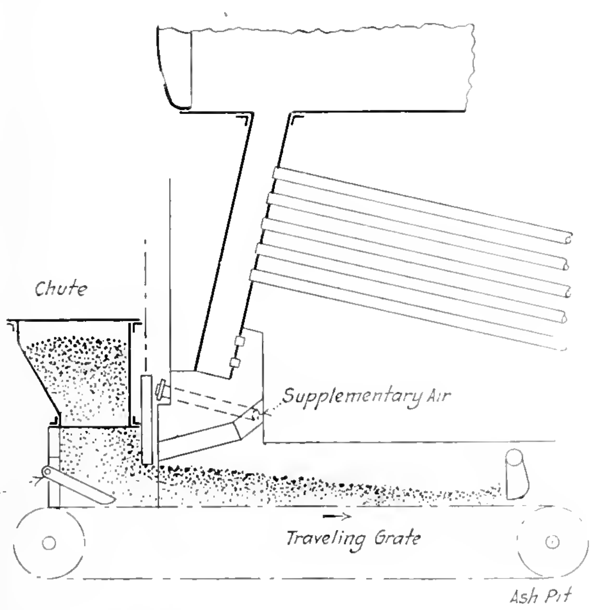

Fig. 1 Traveling Grate with Producer Hopper

It would appear, therefore, that stationary boilers are the main prospective consumers of coke.

It has been stated on many occasions, however, that with coke the boiler cannot deliver as much steam as with coal, especially when working at overload. This is due to the unsatisfactory flame formation resulting from the lack of volatile compounds (1 to 2 per cent in coke as compared with 20 to 30 per cent in coal) and also to the slower combustion of coke equivalent to a lower grate output. Hence, when it is impossible to increase the grate area, the output of steam is apt to fall off.

Likewise lower superheater temperatures have to be taken into consideration, as the exhaust gases enter the superheater at a lower temperature than when coal is used, due partly to the shorter flame and partly to greater excess air.

Coke firing makes greater demands on the fireman. It is recommended that in large plants those boilers that carry normal load be fired with coke, while the peaks of the load curve should be taken care of by boilers equipped for mixed or straight coal firing.

As regards the grate construction it was obvious that the traveling grates designed for coal would not do for coke. This problem was solved by subjecting the coke to a generator action. This means that the coke was brought to a bright glow in a separate hopper and from there delivered on to the traveling grate in a layer from 0.4 m. to 0.5 m. (1.31 to 1.64 ft.) deep, depending on the size of the coke. On the grate the coke was burned in a gradually decreasing depth, as shown in Fig. 1. At the end of the grate slag pockets were provided to prevent too much air from entering.

In order that the combustion should go on properly, it is important to maintain a powerful fire in the lower part of the auxiliary hopper, the purpose of which is to ignite the mass of coke lying above it. A sort of hearth is employed, so arranged that it has nothing to do with the advance of the fuel toward the

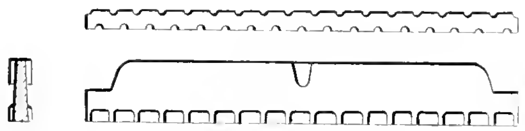

Fig. 2 Nozzle Grate Bar

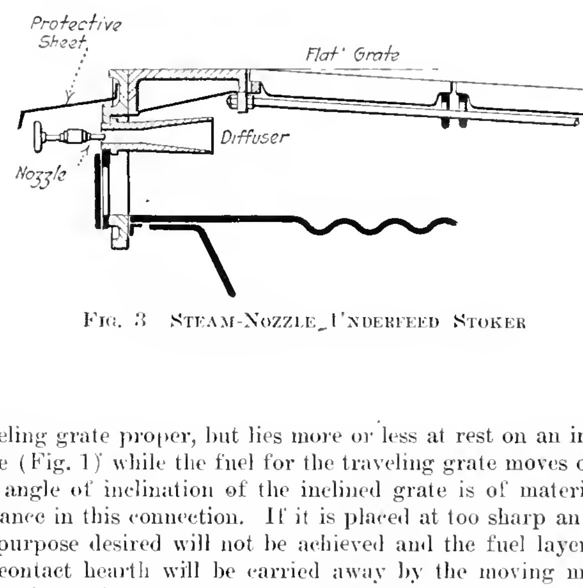

Fig. 3 Steam-Nozzle Underfeed Stoker

traveling grate proper, but lies more or less at rest on an inclined grate (Fig. 1) while the fuel for the traveling grate moves over it. The angle of inclination of the inclined grate is of material importance in this connection. If it is placed at too sharp an angle, the purpose desired will not be achieved and the fuel layer from the contact hearth will be carried away by the moving mass of coke, which will result in stopping the ignition of the coal in the hopper and "freezing" the latter.

The producer action of the auxiliary hopper, together with the deep layer of fuel, favor the production of carbon monoxide and hence flame formation, which is highly desirable. In order, however, to bring about a complete combustion of the gases, it is necessary to admit fresh air directly into the combustion space, which can be done most simply by means of tubes passing through the fire arch.

Several German concerns have devoted a considerable amount of effort to the study of coke combustion. Some of the results of this investigation were published in 1916 in a German publication; from that publication are taken the data of an evaporative test given in Table 1.

The following should be noticed in this connection: The heat balance is very good at the efficiency of 73 per cent, and with the factor of evaporation of 6.7 as compared to the efficiency of 71.5 per cent and the factor of evaporation of 7.5 of the same boiler with coal firing. Should the prices of fuel be proportional to the factors of evaporation and no other considerations enter into the question, the test would indicate that coke is just as good a fuel as coal.

The CO_2 content of 12.5 per cent is quite good and tends to

indicate that there was no particular excess of air. At the same time it should be borne in mind that this test was carried out under very favorable conditions. In particular the coke was quite carefully sorted so that the lumps were between 70 and 90 mm. (2.7 in. to 3.5 in.) in size and approximately uniform.

TABLE 1 EVAPORATIVE TEST OF A COKE-FIRED BOILER

Heating area of boiler, sq. m.	245.0
Grate area, sq. m.	5.3
Fuel, metallurgical coke	
Lump size, mm.	70 to 90
Duration of test, hr	6
Feedwater, by volume, liters	23,900
Feedwater, by weight, kg	23,309
Feedwater temperature at boiler inlet, deg. cent.	80.3
Steam pressure, gage, atmospheres	10.8
Steam temperature, deg. cent.	367.7
Heat content of steam (according to Mollier tables), kg-cal. per kg	765.1
Heat content of feedwater, kg-cal. per kg	80.3
Heat of evaporation, kg-cal. per kg	684.8
Total weight of fuel, kg.	3475
Residues of combustion, kg.	435
Residues of combustion in relation to total fuel, per cent	12.5
Exhaust-gas temperature at damper, deg. cent.	305
Boiler-room temperature, deg. cent.	25
CO_2 content of exhaust gases, per cent	12.5
Draft at the damper, mm. of water	16
Steam generated per kg. of coke, kg	6.7
Steam generated per sq. m. of heating area per hour, kg.	15.9
Fuel consumption per sq. m. of grate area per hour, kg	109
Heat value of fuel kg.-cal.	6280
Combustible in the ashes, per cent	7.7
Heat Balance	
Efficiency of boiler and superheater, per cent	73.0
Smoke-stack losses (according to Siegert tables), per cent	14.5
Heat losses through unconsumed combustible in the ashes, per cent	0.8
Losses through radiation, etc., per cent	11.7
	100.0

An entirely different picture is obtained when the tests are made with unsorted coke, varying in size from breeze up to 90 mm., with the breeze and dust content at about 50 per cent. In these tests the CO_2 content fell from more than 12 per cent in the previous test to as low as 3.5 per cent, a clear indication of the fact that the irregular size of the material caused an excess admission of air.

The other data of the test are essentially of the same character, which led the Rhine Association for the Inspection of Steam Boilers to the conclusion that in the present state of combustion engineering the use of unsorted coke on traveling grates is uneconomical, and further, that the irregularity of the combustion process leads to a considerably diminished output of the boilers.

It appears also that overloading the boiler leads to an excessive wear of the grates and cannot be maintained for any length of time. On the other hand, it appears that coal-firing installations can be converted to coke firing with comparative ease by the employment of steam jets as auxiliaries in the production of draft.

This arrangement can be used particularly well with fine coke, when either a grate with small interspaces may be used, or, still better, a so-called nozzle grate bar designed substantially as shown in Fig. 2.

In order to raise the air pressure under the grate the steam nozzle is led into the smaller end of a conical tube (diffuser) whereby the air compression is raised from 15 to 20 mm. of water. As shown in Fig. 3, the air suction occurs through the ring-shaped space between the nozzle and the tube. In accordance with the size of the furnace one or more nozzles may be used side by side.

The use of the Wilton grate and the evaporator grate in connection with water-tube boilers are also referred to. (*Zeitschrift fur Dampfkessel und Maschinenbetrieb*, vol. 42, no. 9, Feb. 28, 1919, pp. 57-61, 4 figs. d.)

HYDRAULIC ENGINEERING

Bucket and Waste-Water Turbines

Investigations on Bucket Turbines, E. Reichel and W. Wagenbach. (*Zeits. Vereines Deutsch. Ing.*, 62, pp. 822-829, Nov. 23, and pp. 870-876, Dec. 7, 1918). In an earlier series of investigations (ibid., pp. 441 et seq., 1913) the behavior of various types of buckets *A* to *J* was examined under the same load and stress and the results were compared. With the exception of the *G*-bucket, all were obtained for a jet diameter of 30 mm.; jet distance (from center of wheel) of 275 mm.; and head of 100 m. The *G*-bucket was developed for a jet diameter of 40 mm. and for high speeds, other conditions being as before. Four different sizes of *G*-buckets were tested, all with nozzle and needle No. 6. The bucket notch was of the same width (40 mm.) in each case, thus permitting the same diameter of jet to be used throughout. Various numbers of buckets were mounted on the two sizes of disk, and so arranged that for each disk diameter the jet distance was the same for all sizes of bucket. From the results given in this paper it is possible to determine the most favorable construction for any new turbine using *G*-buckets in conjunction with No. 6 nozzle and needle, and working within the conditions and limits for specific speed determined by these investigations. Incidentally the investigations bring out a number of points concerning constructional details as well as considerable information relating to operating phenomena.

The linear dimensions of the four bucket sizes used are in the ratio 0.8: 1.0: 1.2: 1.35. At least four different numbers of buckets were tested for each size of disk and bucket. A complete statement is given of all the essential data, and two- and three-dimension curves are plotted showing the efficiency and other operating characteristics under various conditions. Owing to the number of variables concerned, reference must be made to the original for details. (*Science Abstracts*, Section B—Electrical Engineering, vol. 22, pt. 4, no. 256, April 30, 1919, Item 246, p. 120.)

Waste-Water Turbines. H. Baudisch. (*Zeits. ges. Turbinenwesen*, Nos. 16, 17, 18, 1918. *Elektrot. u. Maschinenbau*, 36, pp. 547-548, Dec. 22, 1918. Abstract.) The energy in the effluent water of turbines can be utilized in waste-water turbines. If H = fall in meters, and c_s = velocity of outflow from suction pipe in meters per second, the effluent energy, hitherto wasted, is $k = c_s^2/2g$. According to the construction and speed of the turbine, h may be from 5 to 15 per cent of H. The waste-water turbine being connected behind the main turbine, the constructional problem is to build a compound turbine dividing the fall very unequally. Axial, radial, or axial-radial turbines may be used, and there is no restriction on the construction of the turbine, the shaft length or the method of building in. The only stipulation is that both turbines be full-stream machines. However, although there is no difficulty in building turbines for the same flow under different heads, it is very difficult to obtain the same speed in both cases. The problem is simplified if the turbine speeds be different and, say, a belt transmission be used to allow for this. If u be the ratio of the belt transmission, and n'_1, n'_2, the turbine shaft speeds, then $n'_1/n'_2 = u\sqrt{(H_2/H_1)}$. If $H_1 = 4H_2$, $Q'_1 = Q'_2/2$, and $n'_1 = un'_2/2$; and $u/2$ may be so chosen that the two turbines work at maximum efficiency. An arrangement offering many advantages is to use the waste-water turbine to drive a d.c. generator which acts as exciter to a three-phase alternator driven by the main machine and also serves station lighting and other d.c. circuits. If the two turbines are coupled (this being the cheapest arrangement), the governing gears must be suitably connected to maintain the distribution of head under all conditions. Such interconnection is effected easily where the electrical equipment is employed. The auxiliary turbine will always run faster than the main turbine: usually $n_{s_1}/n_{s_2} = 0.4$ to 0.8. A gain in power of from 5 to 10 per cent is obtainable by the use of waste-water turbines, the only additional investment being the cost of the latter. (*Science Abstracts*, Section B—Electrical Engineering, vol. 22, pt. 4, no. 256, April 30, 1919, Item 245, pp. 119-120.)

INTERNAL-COMBUSTION ENGINEERING

What the Germans Found from Tests of a Captured Liberty Motor

Liberty Motor, Otto Schwager. Account of a Liberty motor captured by the Germans with the English bomber Hyderabad No. 3, built at the Westland Aircraft Works.

The account is both descriptive and critical. Several interesting features are pointed out. Thus, in connection with the water circulation system, it is stated that on the basis of 80 liters (21 gal.) per hp.-hr. and a maximum engine output of 400 hp.

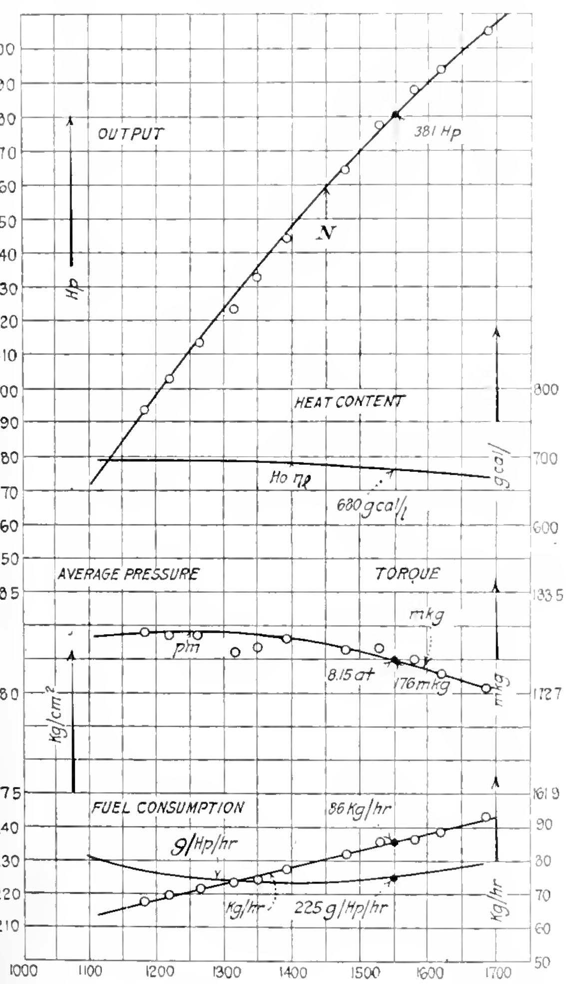

Fig. 4 Data of German Tests on the Liberty Motor

ı circulation of 8.9 liters of water per second would be required. ın the article a curve is given showing the output of the water-irculating pump. This curve indicates that not more than half ıf that amount is actually obtained with a pressure of between ive and six meters (19.6 ft.) of water. Therefore, as compared vith the usual German practice, a radiator of about twice the sual dimensions is necessary with the Liberty engine, and a ange of cooling in the radiator amounting to 10 deg. cent., in rder that the necessary amount of heat should be carried off by ıe air.

An interesting series of curves is presented in Fig. 4, which ives the test data of the captured motor with the standard Zenith ırburetor.

The following comment is given: The curve of output, as funcon of the number of revolutions, is unusually good, which is cribed mainly to well-selected valve-opening cross-sections to-ther with moderate velocity of the flow of gases through the ılves. The fuel consumption of 226 grams (0.49 lb.) per hp.-hr. called very good for "foreign" (which means non-German) gines. The output at 1550 r.p.m. was 381 hp., which is somewhat less than the nominal rating of 400 hp., but it is stated that it is likely that an output of 400 hp. could be secured at that speed with a different setting of the carburetor.

The weight of approximately one kilogram per horsepower is said to be very good.

The general opinion of the motor is that its construction and weight are very good and that the ignition system is novel. The only objection made as regards the ignition system is in respect to the starting of the engine.

The direct drive of the air propeller is considered to be a basic defect of construction, in that with a motor of such a high output it is possible to secure an efficient propeller operation only by reducing the speed in revolutions. It is considered desirable that the motor should be equipped with a reducing gear.

In order to increase the output it would be further necessary to raise the speed of revolution of the motor as high as possible, say about 1800 r.p.m., which would, however, necessitate a redesign of the pistons and connecting rods. In this way, it might be possible to raise the motor output to about 500 hp., maintaining the propeller speed at its most efficient level and reducing the unit weight, including water and oil, to 0.9 kg. (1.9 lb.) per hp. (Der Liberty-Flugmotor, Otto Schwager, *Der Motorwagen*, vol. 22, No. 5, February 20, 1919, pp. 75-80, 20 figs., *e*)

Italian Diesel Engine for Submarine Use Developed During the War

Tosi Diesel Engines for Submarines. The Tosi Company has built a considerable number of Diesel engines for submarines both on the 2-cycle and on the 4-cycle principle. Table 2 for the first time gives in detail test results of these engines.

TABLE 2 COMPARATIVE DATA OF TESTS OF TOSI DIESEL ENGINES FOR SUBMARINES

	Full Load	Full Load	Three-quarter Load	Half Load	Overload
Type of engine.....	Two-cycle	Four-cycle	Four-cycle	Four-cycle	Four-cycle
Number of cylinders	6	8	8	8	8
Duration of trial, hr.	...	36	96	12	1
Power, hp.........	1300	1300	950	650	1485
Revs. per min......	300	300	260	240	...
Fuel-oil consumption, lb. per b.hp-hr....	0.540	0.390	0.410	0.438	...
Lubrication-oil consumption, lb. per b.hp-hr.........	0 0334	0.0180	...	...	...

The conclusions arrived at as a result of these trials were in favor of the 4-cycle type on account of lower fuel- and lubricating-oil consumption and greater flexibility. At the same time it should be borne in mind that they have built a considerable number of very large 2-cycle engines which are running quite satisfactorily and it is possible that for very large powers the 2-cycle engine may be at least as good as the 4-cycle.

The article for the first time gives drawings for certain interesting details of construction.

Thus, Fig. 5 shows the gudgeon-pin construction with the sleeve keyed on to the pin proper and forming the bearing surface. This sleeve permits of a reduction of pressure in the gudgeon-pin bearing from about 2000 lb. per sq. in. to 1400 lb. The bearing is force-lubricated by a supply of oil under pressure through the hollow connecting rod.

The piston crown is made concave to increase the efficiency of oil cooling (its outward shape being somewhat like that in the Willys-Knight engines built in this country).

Two exhaust valves per cylinder are provided but they are placed in separate cages and do not sit in the cylinder head as in the slow-speed engine. Although the diameter of each valve

is relatively small (there being two per cylinder), the valves are internally water-cooled, the water supply being by means of a spiral pipe attached to a spiral nut on the top of the exhaust valve spindle. The construction of the valve and its cage is shown in Fig. 6. The inlet valves sit in the lower face of the cylinder head. The main water-cooled exhaust connecting pipe is fitted internally with a light spiral baffle to prevent interference

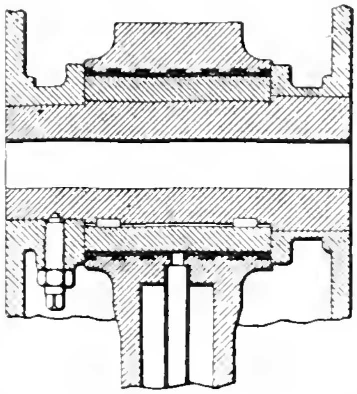

Fig. 5 Gudgeon-Pin Construction for Tosi Submarine Diesel Engine

of the exhaust of one cylinder with that from another, which is necessary since with an 8-cylinder 4-stroke-cycle engine two cylinders will exhaust at the same time at certain points in the revolution, as indicated by one of the diagrams in the original article.

The 4-cycle engine is not fitted with any starting device and is started electrically by the main propelling motors or by a separate starting engine. There are, however, certain objectionable

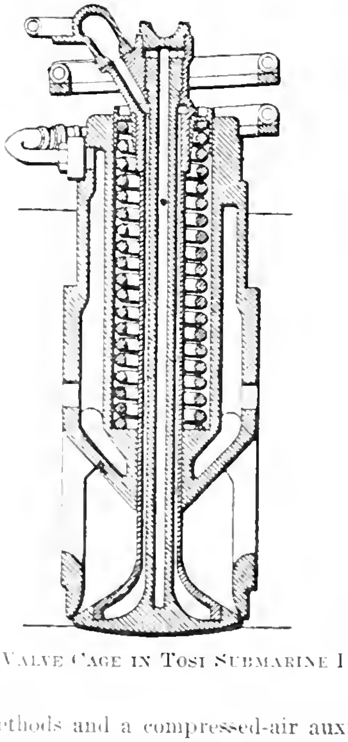

Fig. 6 Valve and Valve Cage in Tosi Submarine Diesel Engine

features to such methods and a compressed-air auxiliary starting engine has been designed for starting by compressed air. This engine has three radial cylinders and drives a pinion with teeth engaging with the periphery of the flywheel. These teeth are slightly spiraled in order to keep in engagement as long as the starting motor is driving, but when the main engine picks up and becomes the driver the thrust of the spiral teeth pushes this pinion forward sufficient to throw it out of engagement with the flywheel. (*Engineering*, vol. 107, no. 2788, June 6, 1919, pp. 732-734, 8 figs., *de*)

LUBRICATION

Economical Lubrication of Steam Engines, K. Schmid. (*Würtemberg Revisions-Verein, Geschaeftsbericht*, 1915. *Elektrot. u. Maschinenbau*, 35, pp. 194-195, April 22, 1917. Abstract.) The data presented are derived from material collected by inspecting a great number of working installations. Only in five engines among those investigated was there a really low consumption of lubricating oil; the minimum was 0.178 gram of cylinder oil and 0.23 gram of bearing oil. In order to obtain results applicable to any engine, the oil consumption must be referred to the actual engine dimensions rather than to the horsepower developed. The temperature of the cylinder walls and their area are of primary importance in determining the oil consumption. The piston speed is also an important factor; and so is the diameter of the low-pressure cylinder in multi-cylinder engines. If D_n = diameter of cylinder (low-pressure cylinder in multi-cylinder engine); s = stroke, both in meters; n = r.p.m.; and K = constant; then the consumption of cylinder oil in grams per hour is given by: $O_s = KD_n \times \pi \times sn/30$. Denoting by μ the term $K\pi/30$, we have $\mu = O_s/D_n sn$. In the five most economically lubricated engines, O_s = 99.1, 100.6, 164.5, 148, 180 grams per hour and corresponding values of μ = 1.275, 1.633, 1.48, 1.6, 1.6 respectively. The author concludes that μ may be as low as 0.8 or 1.0 before wear occurs. With $\mu = 1.6$ there is about 50 per cent saving in oil compared with present consumption, and this saving may be increased to 75 per cent if special efforts be made.

It is recommended that oil separators be installed in the exhaust, and that the separated oil be cleansed and used again for lubrication; also, that the exhaust pipes be drained and the superheat reduced. An allowance of oil on the basis of $O_s = 1.6\ D_n sn$ should suffice, and a premium may be offered to encourage economy. When using drip-feed lubricators with thick oil, the lubricator should be heated by locating it on a hot part of the cylinder, or by other means. Springs and valves are to be avoided in lubricators. Improved bearings and lubricators save oil. Graphite often makes possible important economy in oil. Suitable greases may replace considerable quantities of oil, especially in bearings. "Tar fat" oils are a useful substitute for petroleum oils in bearings but not in cylinders. The author considers that 90 per cent saving in cylinder oil is possible. A saving of 87 per cent in bearing oil has already been effected. (*Science Abstracts*, Section B—Electrical Engineering, vol. 22, pt. 4, no. 256; April 30, 1919, Item 230, pp. 114-115.)

MOTOR-CAR ENGINEERING

Motor-Car-Engine Governors of German Design

Governing of Motor-Car Engines, Pretorius. Description of some of the governor devices developed in Germany.

The devices shown do not represent anything radically different from those used in this country. Of interest is the governor for aircraft motors diagrammatically shown in Fig. 7, the purpose of which is to cut out ignition in case the motor exceeds the desired speed of revolution. The underlying idea in this governor is that in the case of the rupture of the transmission system, the engine may run away to a dangerous extent. It should be borne in mind, however, that the cutting out of the ignition when the engine has reached a very high speed of revolution may produce dangerous stresses in the engine parts.

The device shown in Fig. 7 is so designed as to obviate this to a certain extent. At the normal speed of rotation the governor *a*, and the spindle *b* controlled by it, take the position indicated in the figure. As this speed is exceeded the governor takes gradually the position indicated in the figure in broken lines, and thereby the ignition apparatus is short-circuited by passing the current through the engine frame mass *f*, and the ignition system is put out of action. In order to restart the engine the spring *g* has to be brought by hand into its original position where it engages with the catch *c*.

Fig. 8 shows an interesting device, the purpose of which is to keep several engines running at the same speed. The speed indicators of various engines are provided with sliding contacts so

arranged that the ignition of the engine running beyond the desired speed is cut out until the engine reaches a certain lower speed.

It is not quite clear how the engine of which the ignition has

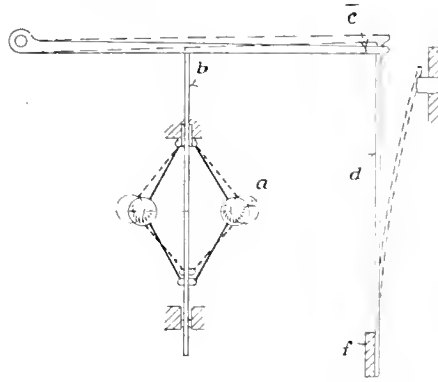

FIG. 7 AIRCRAFT-ENGINE GOVERNOR

been cut out is restarted, unless this is done by the driven element utilizing the power of the engines still running. (Die Regelung der Kraftwagenmotoren, *Der Motorwagen*, vol. 22, no. 8, March 20, 1919, pp. 138-142, 5 figs.)

Recent Developments in Design of Small and Medium-Sized Turbines for Mechanical Drives

TURBINES FOR MECHANICAL DRIVES, R. R. Lewis. A comparatively recent development in the construction of small and medium-sized turbines are the units intended for the direct drive of pumps, fans, and other moderate-speed apparatus.

Turbines of this type are often located in basements and similar more or less inaccessible places where they are likely to receive very little care and attention, and must be therefore of a rugged and simple construction.

This can be secured by the utmost care in design and manufacture and by the use of the best material throughout, conditions which are very difficult to meet because it is necessary that the units should be of moderate cost and at the same time suitable for a wide range of operating conditions. For instance, in driving centrifugal pumps, the speed depends largely on the head under which a pump is to operate; and turbines for this service must run at speeds from 800 to 3600 r.p.m. Again, the steam pressure may be anywhere from 75 to 200 lb. or over, and the back pressure may be from atmospheric pressure to 20 or 30 lb., or the turbine may be required to operate with a vacuum.

To build a special turbine for each combination of conditions, of course, would be impossible; but practically the same result is secured by designing certain standard elements, a number of which can be combined to form a complete turbine that will exactly fit any particular case.

In the design of the type L turbine of the General Electric Company, the plan of construction involves the use of one, two, or three bucket wheels, and a variation in the length of the buckets and the arc of steam admission through the first stage nozzles, in addition to which the size of the steam and exhaust connections is varied and also the governor parts for regulation at different speeds.

The turbine (Fig. 9) is of the Curtis impulse type, in which the steam is given relatively high velocity by passing through a divergent nozzle. In entering the turbine the steam passes first through an emergency valve chest, if one is used; then through a steam strainer, and next through the governor valve. From this it enters the turbine proper through the first-stage nozzles, and after passing through the buckets of a single-stage turbine goes out of the exhaust opening.

The governor is of the centrifugal type and is mounted on the

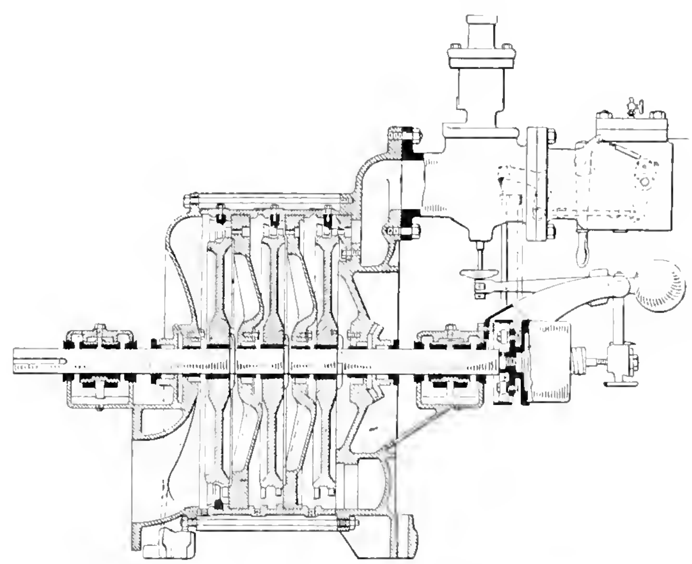

FIG. 9 CURTIS IMPULSE TURBINE FOR MECHANICAL DRIVE

end of the shaft. It operates, through a bellcrank, the governor valve of which is of the double balanced poppet type.

By means of a simple device the speed may be altered while the turbine is running, the governor continuing to exert full control at the altered speed. An emergency governor may be fitted to the machine to shut off the steam supply in emergency, and prevent excessive speed. Hand valves may be used for operation at two different steam pressures. These valves modify the effective capacity of the nozzles. (*General Electric Review*; vol. 22, no. 6; June, 1919; pp. 438-442; 12 figs. *d*)

RAILROAD ENGINEERING

Startling Savings in Power Achieved by Applying Aeronautical Experience to High-Speed Locomotives

THE WIND RESISTANCE ON A TRAIN, C. F. Dendy Marshall. This article is abstracted partly for the information which it contains and partly because it presents a good example of the benefits of what is known as the cross-fertilization of sciences, that is, the application in one branch of science of theory in another and apparently unrelated branch.

It has been known for a number of years that wind resistance affects the power consumed in propelling fast trains, but little or nothing has been done actually to take care of this condition. The author mentions only the fact that about 25 years ago on the South-Western Railway, Mr. Drummond made some of his

smokebox doors conical in shape, a plan followed on some continental railways. With the same end in view a wedge formation has been adopted on the Paris, Lyons and Mediterranean Railway.

It might be added here that the question of wind resistance attracted considerable attention in connection with the high-speed electric railway tests on the experimental line at Zossen, Germany, but the matter had not been placed on a scientific basis until quite recently—thanks to the work which has been done in connection with aeronautics.

The horsepower needed to overcome front wind pressure increases with the cube, not merely of the speed of the train, but also with that of what is called the "created wind," which in the case of express trains may easily exceed 80 m.p.h.

The resistance of the air to a surface moving normally to itself at high speed may be represented by the expression KAV^2, where A is the area exposed, V the speed, and K a constant. If A is measured in square feet and V in miles per hour, $K=0.0033$. At 60 m.p.h. the value of this expression per square foot of transverse surface is approximately $1\frac{1}{4}$ hp., and at 80 m.p.h., 3 hp. If we know the "all out" speed in a calm, say, 70 m.p.h., numerical limits can be assigned between which the speeds will lie for any ratio of train to wind speed, such as are shown in Fig. 10. Here $V \cos \alpha$ represents the resolved part in the direction of travel over wind blowing with velocity V at an angle α to the rails.

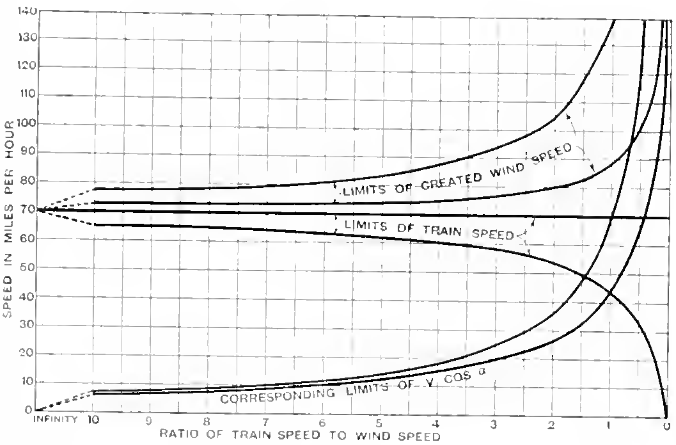

FIG 10 TRAIN-SPEED AND WIND-SPEED CURVES FOR FAST-MOVING TRAINS

The speed of the "created wind" increased with the strength of the natural wind and 80 m.p.h. is quite a moderate figure to take for it.

Aeronautical practice has shown what is the best shape for a body which is to be driven through the air at speeds of the order under consideration. The front should be quite "bluff," a sharply conical or wedge-shaped form not being at all the ideal to be aimed at. What is required is to reduce the transverse flat surface as much as possible, smooth off projections and use gentle curves parallel to the natural flow of the air.

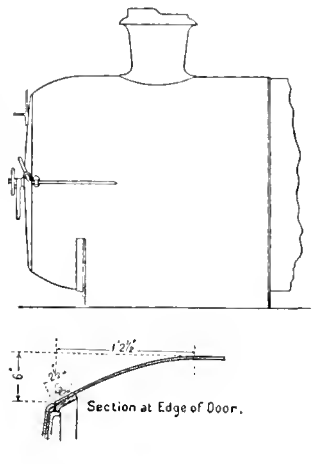
The modern "extension" type of smokebox lends itself very well to modifications in this direction.

Take, for example, a large smokebox 5 ft. 8 in. in diameter. With the very slight bulge usually adopted for the door, the front may be taken as equivalent, as far as the pressure is concerned, to a flat surface—in this case an area a little over 25 sq. ft. The horsepower abstracted for $V=60$ is 32, and for $V=80$, is 75.

It is a simple matter to reduce these figures to a great extent. If the ring at the front end ot the box is made only just large enough to carry the door, as shown in Fig. 11, or, say, 4 ft. 8 in. diameter instead of 5 ft. 8 in., the front surface is reduced by 8.12 sq. ft. The result is a clear saving of 10.5 hp. for $V=60$, and as much as 24 hp. when $V=80$.

But we can go further than this. By forming the door with a radius of something under 3 ft., instead of the usual one, which is frequently as much as 18 ft., we can produce a front door much superior from an aeronautical point of view, such, for example, as is shown in Fig. 12. It is reasonable to expect this smokebox to effect a saving of the order of 25 hp. when the "created wind" speed is 60 m.p.h. and 60 hp. when it is 80 m.p.h.

The author claims that the shape of the locomotive is deserving of careful study and that some modifications of such value as not only to be worth making in the case of new engines, but possibly even worth while to be introduced in the existing ones as they come into the shops for heavy repairs.



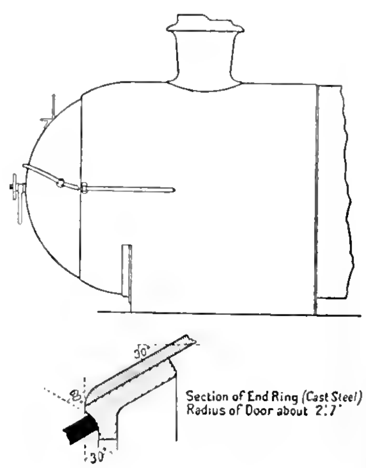


FIG. 11 (LEFT) LOCOMOTIVE DESIGN WITH REDUCED RING AT THE FRONT END OF THE BOX

FIG. 12 (RIGHT) IMPROVED SMOKEBOX DESIGN EFFECTING A GREAT SAVING IN AIR RESISTANCE

Credit is given to the Report of the Electric Railway Test Commission, New York, 1906. (*The Engineer,* vol. 127, no. 3207, May 16, 1919, pp. 473-474, *p.d.*)

LIMIT OF WEAR OF STEEL WHEELS. A test was recently conducted by the testing department of one of the large railroads to determine whether or not steel wheels of $\frac{1}{4}$ in. below the present scrap wearing limit can be used with safety.

For this purpose four rolled-steel wheels which had been in service under locomotive tenders were selected from a lot of scrap wheels. They had treads worn from $2\frac{3}{8}$ to $2\frac{1}{2}$ in. below the new diameter or about $\frac{1}{4}$ in. above the limit mark.

The treads of two of the wheels, Nos. 1 and 4, were turned to a thickness of 1 in. or to the present scrap wearing limit. All flanges were turned to the minimum allowable thickness of 15/16 in. and with vertical surfaces and sharp fillets, similar to the worn conditions developed in service.

The M.C.B. drop-test machine was used for this test, the wheels being supported in a way that caused the entire thrust to be taken by the flange.

For static tests sections 1 in. thick were cut from each steel wheel and tested in a Riehlé testing machine in a manner shown in an illustration in the original article. The arrangement was such as to provide a loading which produced a thrust in a direction parallel to the axis of the wheel and similar to that which occurs in service.

In addition to this three cast-iron wheels were selected from among the scrapped wheels at a large wheel foundry and tested in a manner similar to the steel wheels.

The results showed a decided superiority of steel over cast-iron wheels under the drop test and indicated that a reduction of the thickness of the tread does not affect the strength of the flange in rolled-steel wheels.

The failures of the 1-in. test sections were similar in that all broke in the same way at about the same place. In no case did the break occur at the throat of the flange or at the thinnest section of the tread, but always to one side of the thinnest section toward the center of the tread.

The results of the drop test indicate that the rolled-steel wheels whose treads were turned 1/4 in. below the present scrap wearing limit, with flanges of the minimum allowable thickness, have decidedly stronger flanges than cast-iron wheels, the flanges of which are worn to the minimum allowable thickness.

The nature and similarity of the failures of the 1-in. sections indicate that there is no weakening effect on the flange proper caused by reducing the tread thickness. There is, however, a weakening of the tread due to its own reduced section. (*Railway Mechanical Engineer,* vol. 93, no. 7, July 1919, pp. 437, 438, 6 figs. *ep*)

Pulverized Fuel for the Railways. Abstract of a report presented by a special committee at the 11th Annual Convention of the International Railway Fuel Association, held in Chicago the week of May 19, 1919. This report is based on tests made under regular service conditions just before the war.

A carefully conducted test between two engines of the same class, one burning pulverized coal and the other hand-fired, showed a saving of 23 per cent in fuel burned in favor of pulverized coal.

The main difficulties encountered were the slagging over of the fuel sheet and burning out of the brick arch, and the first was largely overcome by an air jet to blow off the slag accumulations.

The cost of replacing the arch brick largely overcame the saving in fuel, in addition to which there was a delay to the locomotive. In the end a comparison of total costs of hand firing vs. pulverized-coal firing on the locomotives tested, which include cost of pulverizing, cost of handling, cost of arch maintenance, interest and depreciation, showed the hand firing to be most economical. It was, however, thought possible to design a firebox that would avoid burning out the brick arch.

On the other hand, pulverized fuel had been burned satisfactorily, generating all the needed steam and with good control.

The report recommends that experiments should be made to determine if thoroughly air-dried coal ground to the fineness of, say, coarse granulated sugar, and burned in suspension, in specially designed furnaces, will not produce greater overall economy.

It is further suggested that it might be possible to arrange a pulverizing or stoking device that would prepare any grade of coal on the tender and deliver it to the firebox in the pulverized form. (*Power,* vol. 49, no. 25, June 24, 1919, p. 997, *g*)

SAFETY ENGINEERING

Safety in Power-Press Work Without Reduction in Output

Safety Practice in Power-Press Work. Accident records show that more injuries occur on power presses than on any other machine except, perhaps, the circular saw. In practically all press accidents the operator's fingers are caught under the ram at the point of operation. This may be due to the press repeating, or the operator leaving his hand between the dies as the ram descends, or an unexpected stroke caused by accidental tripping.

Analysis of the accidents tends to prove that to prevent them a study of the operation of each press must be made to eliminate if possible the need of the operator placing his hands between the dies, or if this is not practicable, to install a guard which will prevent the operator's hands being caught between the dies when the ram descends.

The most effective way to remove the operating-point hazard is by using the automatic feed, but for some operations it is difficult to develop such a feed.
